1 Introduction

1.1 Overview

This report has been prepared in line with Condition 4.2.2 (a) of Crymlyn Tip Environmental Permit EPR/AP3990LR and subsequent variations (the Permit), which states:

'4.2.2 A report or reports on the performance of the activities over the previous year shall be submitted to the Environment Agency [now Natural Resources Wales] by 31 January (or other date agreed in writing by [NRW] each year. The report(s) shall include as a minimum:

a) A review of the results of the monitoring and assessment carried out in accordance with this permit against the relevant assumptions, parameters and results in the risk assessments submitted in relation to this site and any agreed amendments thereto.'

This report covers the monitoring period January 1st 2023 to December 31st 2023.

1.2 Background

St. Modwen Developments Limited (St. Modwen) acquired responsibility for Crymlyn Tip (the Tip) in 2008, when they purchased the former Llandarcy Oil Refinery from BP. For the Tip to enter 'definitive' closure NRW must be satisfied that a Closure and Aftercare Management Plan has been produced.

St. Modwen appointed Englobe in 2022 to address Improvement Requirements IP1 and IP2 of permit EPR/AP3990LR, including preparation of a Closure and Aftercare Management Plan for agreement by NRW.

Works associated with IP1 and IP2 are reported under separate cover by Englobe and are subject to separate, ongoing discussions with NRW.

1.3 Summary of Works

The environmental monitoring programme was initially undertaken by Atkins on behalf of St. Modwen until March 2019. From April 2019, PJA were appointed by St. Modwen to undertake elements of the monitoring and to prepare annual reports for submission to NRW.

PJA collect groundwater and surface water samples on a monthly basis as part of the monitoring programme.

GeoEnvironmental Applications Ltd (GAL) have been contracted by St. Modwen to manage the recovery of local free phase oil within the Tip and its peripheries. Alongside oil recovery, GAL carry

out groundwater level and free phase hydrocarbon monitoring within boreholes/sumps and obtain monthly gas readings from available boreholes within/surrounding the Tip.

A programme of environmental monitoring consistent with previous years has been undertaken during 2023.

1.4 Supporting Documents

The previous annual monitoring report covering the year 2022 was produced by PJA and submitted to NRW:

- PJA Crymlyn Tip Environmental Monitoring Annual Report. Ref: 04020-PJA-23-XX-RP-R-0084. Dated June 2023

Additional information relating to the history, operation, previous assessments, and risk assessments of the Tip are presented in the following reports:

- Atkins (2013) Coed Darcy – Hydrogeological Risk Assessment Crymlyn Tip;
- Atkins (2013) – Coed Darcy – Landfill Gas Risk Assessment and Gas Management Plan;
- Atkins (2017) – Coed Darcy Crymlyn Tip Partial Surrender of Coed Darcy Wetlands. EPR/AP3990LR/S003 Site Condition Report. Ref 5041216-RAP-RPT-0001788;
- Atkins (2019) – Coed Darcy Crymlyn Tip – Environmental Permit Monitoring. Ref: 5041216. Dated: 31/01/2019;
- Natural Resources Wales (2019) – Compliance Assessment Report. Ref: CAR_NRW0034811. Dated: 13/03/2019;
- PJA (2019) – Coed Darcy – Crymlyn Tip Factual Summary Report, April – September 2019: Ref: 4020-PJA-19-XX-TN-R-005. Dated 22/10/2019; and
- PJA (2020) – Crymlyn Tip – Environmental Monitoring Annual Report. Ref: 04020/OUT/0027. Dated April 2020.
- Coed Darcy (2021) – Crymlyn Tip Environmental Monitoring Annual Report, February 2021 –Ref: 4020-PJA-20-XX-RP-R-0045
- PJA (2022) – Crymlyn Tip – Environmental Monitoring Annual Report. Ref: 04020-PJA-21-XX-RP-R-0063. Dated March 2022.
- PJA (2023) – Crymlyn Tip – Environmental Monitoring Annual Report. Ref: 04020-PJA-23-XX-RP-R-0085. Dated June 2023.

It is assumed that the reader has access to the above documentation and is familiar with previous assessments undertaken. This report is not intended to repeat or reproduce findings of previous assessments in any great detail.

1.5 Limitations

This report has been prepared by PJA, on behalf of St. Modwen, for submission to NRW. This report shall not be relied upon or transferred to any other parties. If an unauthorised third party comes into possession of this report, they rely on its contents at their own risk.

The findings within this report are based upon information gained from a variety of sources and field measurements as detailed within this report which PJA believes are reliable. Nevertheless, PJA cannot guarantee the authenticity or reliability of third-party information.

The conclusions made within this report are based on relevant guidance available at the time of writing.

2 Site Setting

2.1 Site Location and Description

The Tip is located in the historical 'Containment Area' in the western section of the wider Coed Darcy development at the former Llandarcy Oil Refinery. The 'Containment Area' also includes a series of lagoons and wetlands. The containment area is shown in Appendix A on PJA drawing 04020-A-0110-00: Notable Areas & NRW Discharge Consent Points.

The area covered by the Permit, and to which this report relates, is shown on drawing 04020-A-SK201-P2 and consists of the 'lower tip' in the west and the 'main tip' in the centre and east. To the north is Crymlyn Bog and to the south of the permitted area are the wetlands within the Containment Area which were surrendered from the Permit in 2017.

2.2 Brief Site History

When the refinery opened in the early 1920s the 'Containment Area' comprised a series of lagoons and wetlands, congruent with Crymlyn Bog. The lagoons were initially constructed during the operational years of the refinery and were intended to intercept oil, preventing it from entering Crymlyn Bog. There are three lagoons in the Containment Area: Crymlyn Bog Lagoon (approx. 10,500m^3), South Bay (approx. 4,450m^3) and West Bay (approx. 1,500m^3).

Prior to the Second World War an ash bund was constructed around the Containment Area to provide a containment area for oil, which may have otherwise flowed into Crymlyn Bog if the tank farm area had been struck by bombs during the war. The ash bund also contained drainage systems, serving the southern half of the former refinery.

In 1977 a waste disposal licence was granted for the Containment Area. The licence granted the deposition of refinery waste, including both inert and potentially hazardous materials. Waste was filled in the area north of the wetlands. No waste has been accepted since 1999 and the landfill has been non-operational since July 2001.

Remedial works have taken place within the wetlands (South Bay, West Bay, and Crymlyn Bog Lagoon) between 2011 and 2015. These works were summarised as part of the submission for the partial surrender of the waterbodies from the permitted area. The partial surrender report (Atkins report reference- 5041216-RAP-RPT-0001788) was submitted to NRW and the Coed Darcy wetlands removed from the permitted area in 2017. The remaining permitted area is outlined in red on drawing 04020-A-SK201-P2.

3 Environmental Setting

3.1 Geology

Published British Geological Survey records indicate superficial deposits at the Tip to predominantly comprise Peat underlain by Devensian Till; however, Peat is absent from the eastern portion of the Tip. Bedrock of the Pennant Sandstone Formation underlies the superficial deposits.

Based on historical borehole logs Made Ground/waste thicknesses are variable but extend to depths in excess of 17mbgl locally. Made Ground generally comprises grey, brown, and black, sandy, gravelly clay, with sand, gravels, and cobbles. Gravels and cobbles consist of bricks, concrete, timber, metal, and ash. Much of the infill material is consistent with waste derived from refinery operations. There are areas where asbestos waste is reported to have been deposited as well as tank sludges, other industrial waste by-products, oil, and tar residues.

Available borehole logs are presented in Appendix B.

3.2 Hydrogeology

Peat is classified as Unproductive Strata and Till as a Secondary (Undifferentiated) Aquifer. The underlying bedrock is classified as a Secondary A Aquifer.

Following an investigation across the wider Llandarcy Oil Refinery, including the Tip, URS produced groundwater contour plots for the bedrock and superficial aquifers (URS Report: 39991-044-785: Final Factual Report Whole Site Investigation BP Llandarcy Refinery 12th August 2005). These plots indicated groundwater in the bedrock beneath the Tip to flow from south to north across the permitted area. Artesian and sub-artesian conditions may be present in the bedrock around the boundary between the Tip and Crymlyn Bog. Monitoring of shallow groundwater beneath the Tip indicates possible local radial flow although this may be distorted by the presence of residual oil and by the heterogeneous nature of the waste material.

For reference the groundwater contour plots taken from the original URS report are presented in Appendix C.

3.3 Hydrology

A ‘peripheral trench’ separating the Tip from Crymlyn Bog to the north is a narrow channel that intercepts groundwater flowing to the north from the Tip. A plywood wall in the trench traps free phase oil, whilst allowing groundwater to flow underneath the plywood into the bog. Oil is periodically collected from the trench (and from sumps and boreholes within the Tip) and sent for offsite processing.

Three water bodies located in the south of the wider Containment Area, namely South Bay, West Bay, and Crymlyn Bog Lagoon, were surrendered from the Permit in 2017.

3.3.1 South Bay

South Bay has a capacity of approximately 4,450m^3 and is located to the south of the Tip. The waterbody was originally created to intercept uncontrolled discharge of free product from the refinery and prevent it from entering Crymlyn Bog.

3.3.2 West Bay

West Bay is approximately 1,500m^3 in capacity and lies to the south west of the Tip. Similar to South Bay, West Bay was installed to intercept uncontrolled discharge of free product from the western section of southern tank farm and prevent it from entering Crymlyn Bog.

3.3.3 Crymlyn Bog Lagoon

Located to the south of the Tip, Crymlyn Bog Lagoon receives inputs from both South Bay and West Bay, prior to discharging into Crymlyn Bog. Discharge to the bog from Crymlyn Bog Lagoon is via a siphon valve and a historical oil-water interceptor located within the ash bund. The outfall from the siphon valve is a NRW consented discharge point, W3, under Environmental Permit EPR/ LB3293HN which is held by St. Modwen.

4 Surface Water and Groundwater Monitoring and Sampling

4.1 Monitoring and Sampling Locations

Current sampling locations are shown on PJA drawing 04020-A-SK201-P3 in Appendix A and are summarised in Table 1.

Table 1: Summary of Monitoring and Sampling Locations

Location ID	Monitoring Type	Response Zone
SW1 –SW6	Surface water	Surface water
Sumps 14 – 21 & 24-28	Groundwater monitoring and oil recovery	Made Ground

MSMW034D	Groundwater monitoring and sampling	Mudstone (Coal Measures Formation)
MSMW034S	Groundwater monitoring and sampling	Gravel (Glacial Deposits)

Location ID	Monitoring Type	Response Zone
MSMW035	Groundwater monitoring	Sandstone (Coal Measures Formation)
MSMW91	Gas and groundwater monitoring	Gravel (Glacial Deposits)
MSMW155D	Gas, groundwater monitoring, and sampling	No borehole log (presumed bedrock)
MSMW155S	Gas, groundwater monitoring, and sampling	No borehole log (presumed superficial deposits)
MSMW227	Groundwater monitoring	Made Ground
MSMW231	Gas and groundwater monitoring	Made Ground
MSMWs232	Groundwater monitoring	Made Ground
MSMW238	Groundwater monitoring	Made Ground

GAL carry out field measurements, monitoring of the groundwater levels and record gas readings from locations installed with a gas bung and tap using a GA5000 gas analyser. PJA carry out monthly groundwater and surface water sampling. Sampling is carried out using a peristaltic pump where possible or bailer where excessive groundwater depth or the presence of free phase prevent the use of the pump.

4.2 Laboratory Analysis

A total of 131 groundwater samples and 70 surface water samples were scheduled for the following suite of laboratory analysis during 2023:

- pH
- Ammoniacal Nitrogen as N*;
- Chloride*;
- Total hardness as $CaCO_3$;
- Dissolved Organic Carbon;
- Dissolved and total metals (arsenic, boron, cadmium, calcium, chromium, copper, lead, mercury, nickel, selenium, vanadium, zinc)*;
- Hardness (total as $CaCO_3$ unfiltered)*;
- Total Petroleum Hydrocarbons Criteria Working Group (TPHCWG);
- BTEX compounds (Benzene, Toluene, Ethylbenzene and Xylenes);
- MTBE (methyl tertiary butyl ether); and
- Polycyclic Aromatic Hydrocarbons (PAH) US EPA 16 (aqueous).

*Analysis not scheduled on samples collected on 3rd August due to a scheduling error.

4.3 Surface Water Sampling Regime

The six surface water locations, SW1 to SW6, were all sampled on twelve occasions during 2023, with the exception of SW1 during the monitoring round undertaken on 11th July, due to the sample point being dry and SW2 on 30th October because of inaccessibility.

Groundwater Sampling Regime

Table 2 shows when each of the groundwater locations has been sampled over the course of 2023. During each sampling visit, collection of groundwater samples is attempted from a number of locations within and surrounding the Tip to provide good spatial distribution. During some sampling rounds it may not have been possible to obtain a sample because of any one or a combination of the following factors:

- difficulty in obtaining a sample due to the presence of free phase hydrocarbons;
- sampling equipment error;
- dense vegetation growth preventing access to the sample point.

5 Groundwater and Non-Aqueous Phase Liquid Monitoring Results

5.1 Introduction

Groundwater level and non-aqueous phase liquid (NAPL) monitoring was undertaken in boreholes and sumps at the Tip during 2023. PJA Drawing 04020-A-SK201-P3 which shows all monitoring locations is presented in Appendix A.

Available borehole logs, presented in Appendix B, have been reviewed to identify response zones for each of the monitoring locations. Response zones are constructed within either waste material, superficial deposits, or bedrock. In a small number of locations, the response zone spans Made Ground and the upper strata of the superficial deposits.

It was not possible to monitor every monitoring location on every round because of access restrictions and blockages within the boreholes. The number of monitoring rounds completed at each location during 2023 is recorded in Table 3.

5.2 Groundwater Level Monitoring

Monthly groundwater level monitoring was carried out across a total of 38 borehole locations during 2023. A summary of the groundwater levels recorded during 2023 is provided in Table 3.

5.3 Non-Aqueous Phase Liquid Levels (NAPL)

Light non-aqueous phase liquids (LNAPL) have been recorded in boreholes and/or sumps during 2023. A summary of LNAPL recorded in boreholes is presented in Table 4 LNAPL recorded in sumps is presented in Table 5. No suspected dense non-aqueous phase liquids (DNAPL) were detected in any of the monitoring locations during 2023.

Table 3: Summary of Recorded Groundwater Levels in Boreholes

5.4 Groundwater and LNAPL Levels Discussion

5.4.1 Groundwater Levels

A review of groundwater level monitoring data collected over the monitoring period shows the majority of lowest groundwater levels were recorded during January and June and the highest groundwater levels were recorded in March.

There is an average variability of 0.84m between the lowest and highest recorded groundwater level in any location which shows a decrease to the degree of groundwater level variability recorded in 2022 (1.40m), 2021 (2.57m), and 2020 (2.70m).

Borehole CBH46 (3.59m) and CBH32 (2.72m) exhibited the greatest variability in recorded groundwater levels. Borehole CBH46 is located in the central area of the Tip where a high degree of local heterogeneity would be expected in the waste material. CBH32 is located in the north of the Tip in an area where saturated ash deposits are prevalent.

Boreholes CBH42 (0.01m), CBH37 (0.04m), and MSMW035 (0.04m) recorded the least variability in groundwater levels. Borehole CBH42 is located in the eastern area of the Tip, where soils comprise waste/Made Ground. Borehole CBH37 is located towards the north of the Tip close to where saturated ash deposits are present and MSMW035 is situated in the far south east of the Tip within Sandstone bedrock.

5.4.2 Light Non-Aqueous Phase Liquid (NAPL) Levels and Distribution

LNAPL has been detected in 26 boreholes out of 36 monitored during 2023. Boreholes where no LNAPL was detected were: MSMW034D, MSMW034S, MSMW035, MSMW91, MSMW155S, MSMW155D, MSMWs232, CBH29, CBH30, CBH43, CBH64, and CBH65. These boreholes are mostly located in the eastern area of the Tip with response zones installed in sandstone, mudstone, peat, and waste/Made Ground. Boreholes MSMW155S and MSMW155D are located beyond the waste area to the south west.

The greatest recorded LNAPL thickness of 1.29m was recorded in CBH2 in April. CBH2 is located in the central region of the Tip, with the response zone installed in waste/Made Ground. LNAPL thicknesses of 1.09m and 0.78m were recorded in CBH32 and CBH39 respectively in June (CBH32) and January (CBH39). Both CBH32 and CBH39 are located in the northern part of the eastern area of the Tip.

The lowest recorded LNAPL thickness was recorded in borehole CBH51 where 0.01m of oil was recorded in August. CBH51 is located within the main landfill area of the Tip.

LNAPL has been detected in six sumps during 2023. The greatest thickness of LNAPL in sumps was recorded in November when a 0.28m thickness of LNAPL was recorded in Sump 19 which is located centrally in the north of the Tip. The lowest thickness of LNPAL (0.01m) was recorded in several sumps (Sump 18, Sump 20, Sump 21, and Sump 27) at various times through the year.

6 Groundwater and Surface Water Quality Assessment

6.1 Assessment Criteria

Results from laboratory analysis of groundwater and surface water samples obtained during 2023 have been screened against relevant Water Quality Standards.

Groundwater data have principally been screened against threshold concentrations ('Drinking Water Standards') in The Water Supply (Water Quality) Regulations 2018, and against Environmental Quality Standards (EQS) in The Water Framework Directive (Standards and Classification) Directions (England and Wales) 2015. The threshold concentrations in The Water Supply (Water Quality) Regulations 2018 have been used to give a broad indication of overall groundwater quality, however they are overly conservative in this instance, because groundwater is not abstracted from the Tip for water supply purposes. The use of EQS is considered to be overly conservative because EQS apply to the receiving surface water.

Surface water data have been screened against EQS in The Water Framework Directive (Standards and Classification) Directions (England and Wales) 2015.

Both surface water and groundwater data have been screened against the specified petroleum hydrocarbon emission limit in environmental permit EPR/LB3293HN for the site drainage from Coed Darcy. Whilst the permit emission limit is not strictly applicable to the SW1-SW6 surface water monitoring locations, or to groundwater in the Tip, it has been used to identify the presence of elevated concentrations of petroleum hydrocarbons in proximity to Crymlyn Bog. The Environmental Permit EPR/ LB3293HN emission limit for 'visible oil and grease' of 5,000 µg/l in surface water has been used to assess total petroleum hydrocarbon concentrations.

Copper, nickel, and zinc have been screened against predicted no effect concentrations (PNEC) values derived using the metal bioavailability tool (M-BAT), taking account of the fact that the respective EQS for these substances relates to bioavailable concentrations. The measured dissolved organic carbon (DOC) concentration recorded within the receiving water body (Crymlyn Bog) exceeded the upper limit of the validated range for copper, nickel, and zinc. As a result, the site-specific PNEC for copper was calculated using a DOC concentration of 15mg/l and site-specific PNEC for nickel and zinc were calculated using a DOC concentration of 20mg/l. The measured pH in Crymlyn Bog exceeded the upper limit of the validated range for zinc and the site-specific PNEC for zinc has been calculated using a pH of 8. Remaining PNEC have been calculated using the average of pH and calcium values recorded in Crymlyn Bog during 2023, in accordance with the WFD UKTAG M-BAT Method Statement (July 2014).

Laboratory analytical data screening is presented in Appendix D.

6.2 Groundwater

Comparison of laboratory analytical data for groundwater against UK Drinking Water Standards (DWS) indicates exceedances for arsenic, lead, and benzene.

There were no exceedances of the available Maximum Allowable Concentration (MAC) EQS for metals with the exception of two exceedances of the MAC-EQS for mercury in CBH29 and CBH46 and two exceedances of the MAC-EQS for lead in CBH64 and MSMW034S. An exceedance of the available MAC-EQS for anthracene was recorded on a single occasion in CBH46.

In relation to the available Annual Average (AA) EQS for metals, the average recorded cadmium concentrations across the groundwater dataset marginally exceed the respective AA-EQS and the average recorded chromium and benzene concentrations exceeds the respective AA-EQS in groundwater.

Twenty-five exceedances of the calculated copper PNEC (3.23µg/l) were recorded out of 120 samples. Copper PNEC exceedances ranged from 4.4µg/l to 31µg/l and were detected in CARW034, MSMW034S, CBH23, CBH29, CBH46, CBH57, and CBH64. The remaining groundwater data are largely compliant with the calculated PNEC for nickel and zinc, with the exception of two recorded zinc concentrations in sample locations CBH57 and CBH64 in early February 2023.

The Environmental Permit emission limit of 5,000µg/l for 'visible oil and grease' in surface water has been used to make an indicative assessment of TPH concentrations in groundwater. The emission limit was not exceeded in any groundwater samples during 2023.

The EQS for 'total ammonia as N' was exceeded based on a calculation of the 90th percentile value for groundwater across the Tip.

6.3 Surface Waters

Surface water data were largely compliant with MAC-EQS and AA-EQS during 2023.

A single marginal exceedance of the cadmium MAC-EQS was recorded at sample point SW4 in early February 2023 and a single exceedance of the lead MAC-EQS was recorded in a sample collected from SW1 in early February 2023.

The average recorded cadmium concentrations exceed the AA-EQS, principally because the limit of detection is slightly higher than the AA-EQS. The average recorded chromium concentrations marginally exceed the AA-EQS.

No exceedances were reported with respect to TPH and PAH.

The surface water data are compliant with the calculated PNEC for nickel. Nine exceedances of the calculated PNEC for copper were recorded in SW1, SW3, SW4, SW5 and SW6. Three exceedances of the calculated PNEC for zinc were recorded in SW1, SW4 and SW5.

7 Landfill Gas

7.1 Landfill Gas Monitoring

Landfill gas monitoring was undertaken by GAL at 13 boreholes across the Tip and its surroundings, using a GA5000 gas analyser. Due to the age of a number of boreholes across the Tip, some headworks are noted to be damaged, and the boreholes therefore cannot be monitored for gas. Of the 13 boreholes that were monitored during 2023, ten are located within the Permit boundary, and three are located outside of the Permit boundary to the south west, as summarised in Table 6.

Table 6: Landfill Gas Monitoring Location Information

Monitoring locations in the Tip	Monitoring locations outside the Tip
CBH20	MSMW155S (located to the south west)
CBH23	MSMW155D (located to the south west)
CBH32	MSMW91 (located to the south west)
CBH49	
CBH51	
CBH52	
CBH57	
CARW008 (located outside fill area)	
CARW009 (located outside fill area)	
MSMW231	

7.2 Landfill Gas Concentrations

The minimum atmospheric pressure reading was recorded as 1004 millibars (mbar) in January and February 2023, whilst the highest atmospheric pressure was recorded as 1029 mbar in April 2023. Monitoring rounds carried out in February, October, and December 2023 were carried out during falling atmospheric pressure events, which represent conditions when positive flow of landfill gas is most likely to be recorded. Landfill gas monitoring data is presented in Appendix E.

Methane (CH_4)

Based on the graph for boreholes in the Tip presented as Figure 2, methane concentrations during 2023 appear to show some variability. Generally, average methane concentrations within the Tip were below 10% with the exception of CBH20, CBH57 and MSMW231. Recorded methane concentrations in CBH20 ranged from 2.50% (May) to 45.10% (October), in CBH57 from 0.1% (Match and August to October) to 12.9% (January) and in MSMW231 ranged from 0.40% (November) to 56.80% (August). The lowest methane concentration of <0.1% was recorded across several monitoring locations in the Tip during the year.

Outside the Permit Area, a maximum methane concentration of 3.50% was recorded in MSMW91 (assumed to be screened with a response zone in granular superficial deposits) in April 2023. The minimum methane concentration of <0.1% was recorded outside the former landfill area in all three monitoring locations on multiple monitoring rounds. Stable recorded methane concentrations in boreholes located outside of the Permit area are shown on Figure 1.

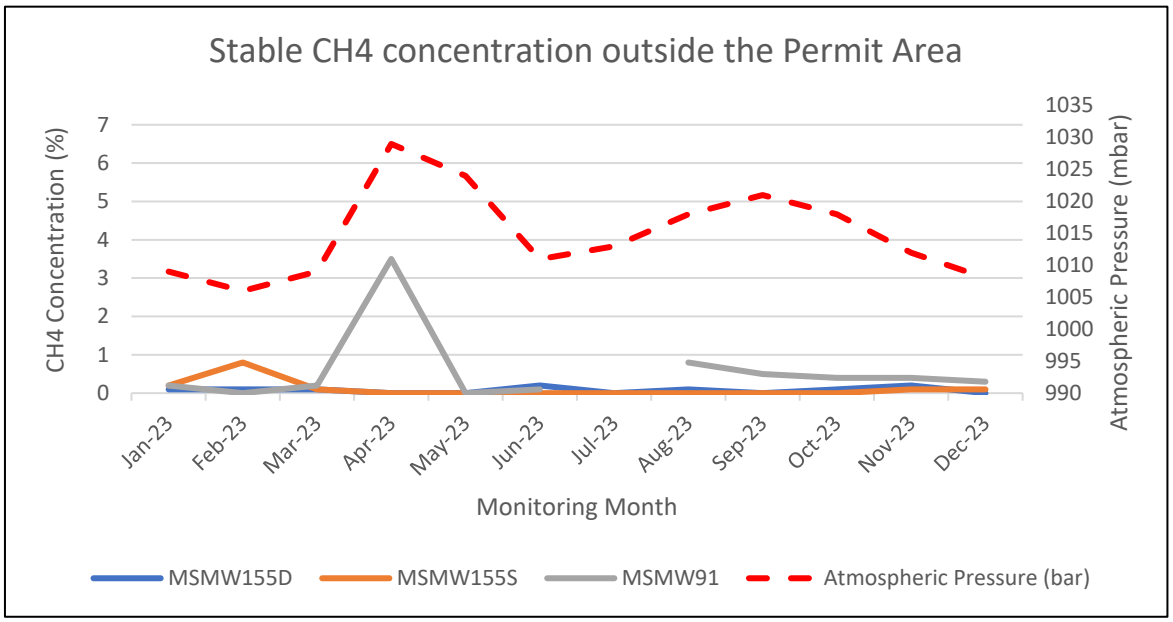

Figure 1: Methane concentrations in boreholes outside Permit Area

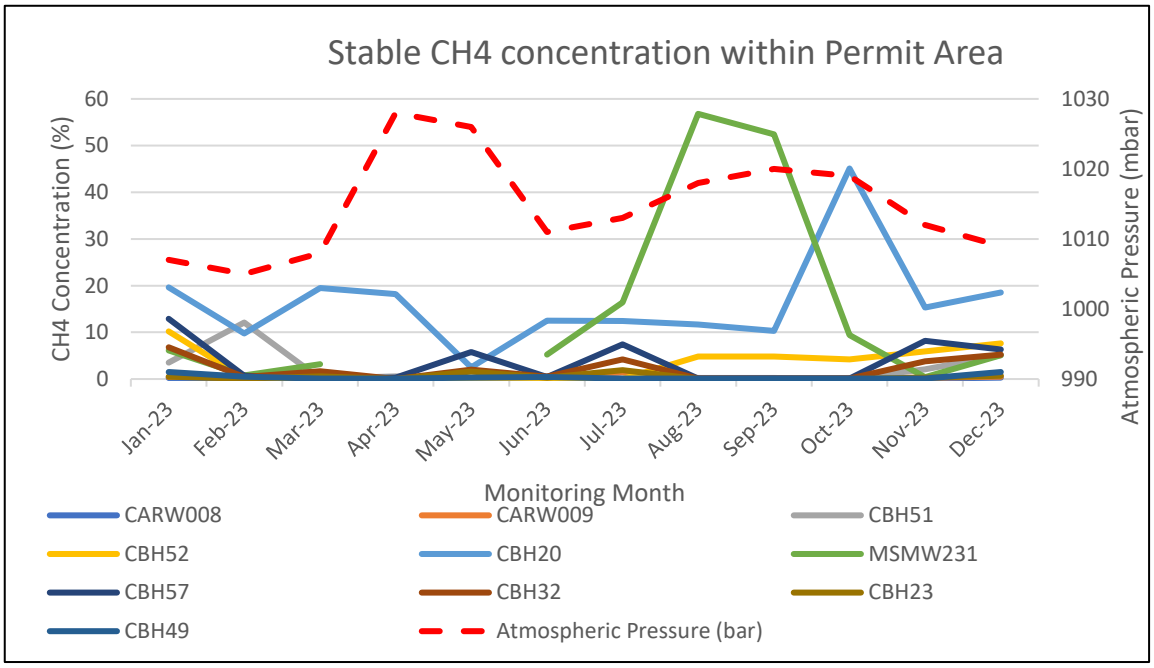

Figure 2: Methane Concentrations in Boreholes within Permit Area

Carbon Dioxide (CO_2)

Based on monitoring data presented in Figure 4 stable carbon dioxide concentrations in the Tip ranged from <0.10% to 11.40%. The maximum carbon dioxide concentration of 11.40% was detected in CBH32 in July and the lowest concentration (<0.10%) detected in several monitoring locations across the Tip.

The maximum carbon dioxide concentration of 5.60% recorded outside of the Tip was in MSMW091 (screened in granular superficial deposits) in April 2023 and the lowest concentration of <0.1% was recorded in MSMW155S and MSMW155D at several points throughout 2023 (screened in superficial deposits and bedrock respectively). Figure 3 presents a graph showing stable recorded carbon dioxide concentrations outside the Permit Area.

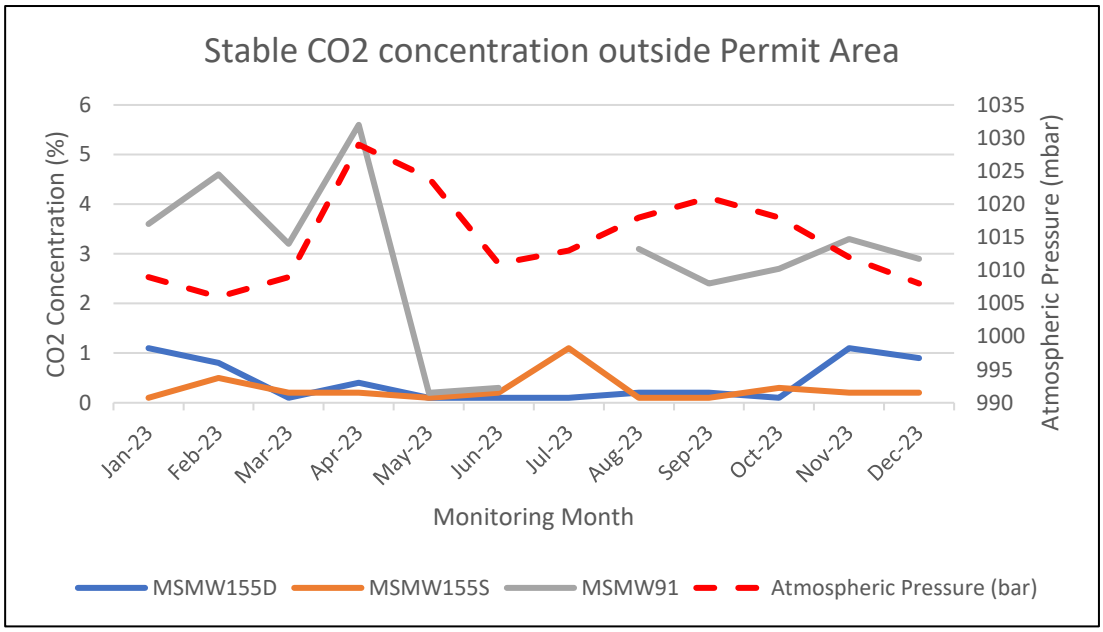

Figure 3: Carbon Dioxide Concentrations in Boreholes Outside Permit Area

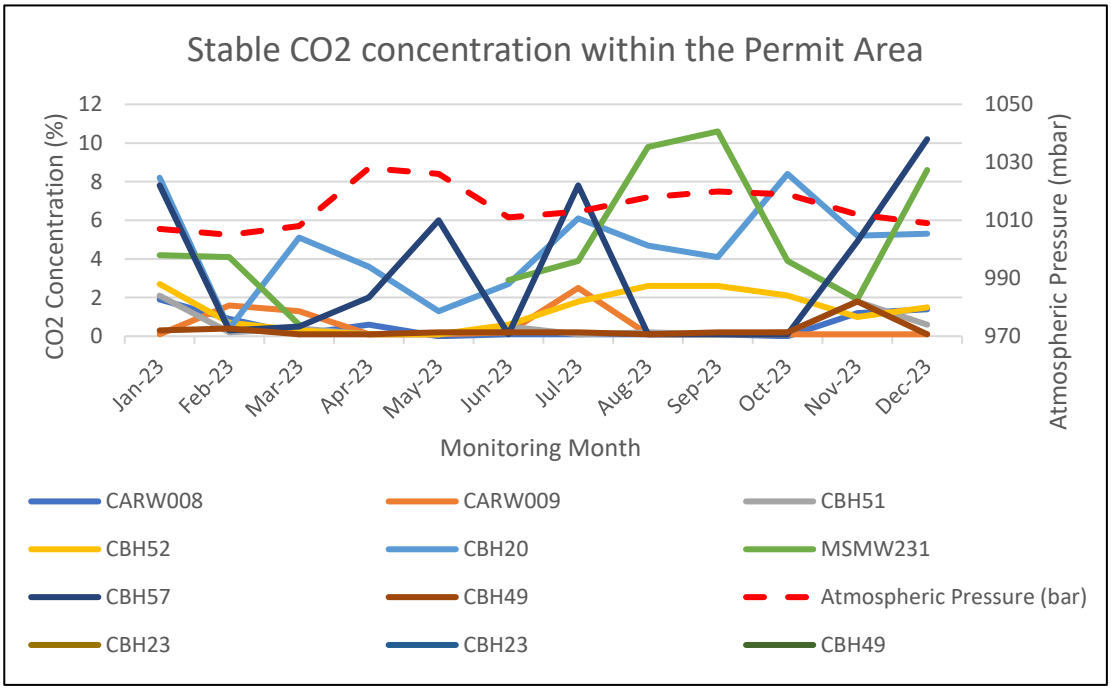

Figure 4: Carbon Dioxide Concentrations in Boreholes in Permit Area

Oxygen (O_2)

Oxygen concentrations recorded in the Tip shown on the graph presented as Figure 6 range from 0.10% to 23.20%, with the lowest concentration recorded in CBH20 in October and also in CBH57 in December. The maximum concentration of 23.20% was detected in CARW008 during June.

Outside of the Tip, oxygen concentrations shown in the graph presented as Figure 5 ranged from 6.30% to 22.90%. The minimum concentration of 6.30% was recorded in MSMW91 in December and the maximum concentration of 22.90% was recorded in MSMW155D in June.

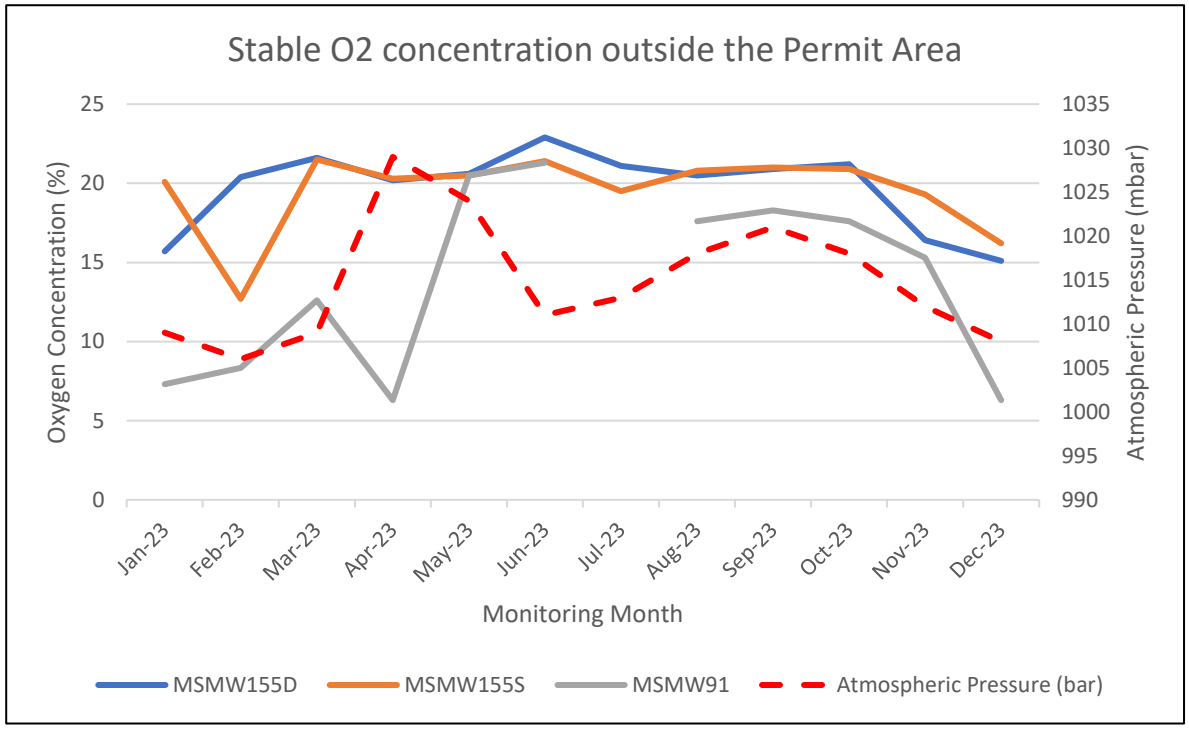

Figure 5: Oxygen Concentrations in Boreholes Outside Permit Area

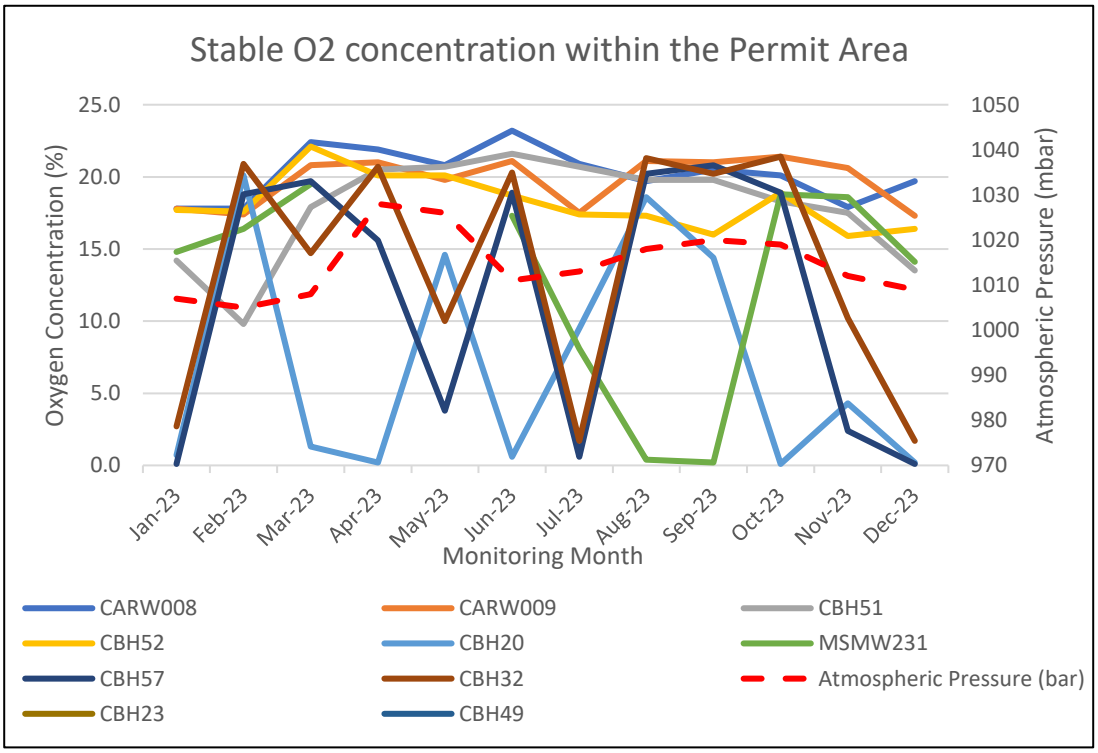

Figure 6: Oxygen Concentrations in Boreholes within Permit Area

Landfill gas monitoring results recorded during 2023 are summarised in Table 7 below.

Table 7: Landfill Gas Stable Concentration Summary

Monitoring location	Location	Methane (%)		Carbon dioxide (%)		Oxygen (%)	
		Min	Max	Min	Max	Min	Max
CARW008	In waste on SE boundary	<0.1	0.5	<0.1	1.9	17.8	23.2

CBH57	In waste within central section	<0.1	12.9	<0.1	10.2	0.1	20.8
CBH23	In waste within central section	<0.1	1.9	<0.1	5	7.5	20.5
MSMW231	In waste within central section	0.4	56.8	0.6	10.6	0.2	19.5
MSMW155s	Beyond W boundary of landfill area	<0.1	0.8	<0.1	1.1	12.7	21.5
MSMW91	Beyond W boundary of landfill area	<0.1	3.5	0.2	5.6	6.3	21.3
MSMW155d	Beyond W boundary of landfill area	<0.1	0.2	<0.1	1.1	15.1	22.9

8 Commentary

Groundwater levels, NAPL, groundwater quality, surface water quality, and landfill gas have been monitored in and around the Tip during 2023.

Groundwater levels were generally most variable in boreholes located in the central area of the Tip during 2023, and lower levels of variability were noted beyond the extent of the landfilled area.

LNAPL levels were variable across the Tip during 2023, however the 'Lower Tip' to the west which has previously undergone removal of bulk sources of free phase hydrocarbons recorded more sporadic occurrences of LNAPL in sumps compared to previous years. No LNAPL was detected in MSMW034S, MSMW034D, MSMW035, MSMW91, MSMW155S, MSMW155D, MSMW232, CBH29, CBH30, CBH43, CBH64, and CBH65. The boreholes where no LNAPL was detected during 2023 are located within the eastern area of the Tip, with the exception of MSMW155S and MSMW155D which are located in the south western area outside of the permit boundary.

DNAPL was not detected during monitoring rounds undertaken in 2023.

Exceedances of the DWS were recorded in groundwater for arsenic, lead, and benzene. Local exceedances were recorded of the MAC-EQS for mercury, lead and anthracene. Marginal exceedances of the respective AA-EQS for cadmium, chromium, and benzene were recorded based on calculated mean groundwater concentrations. Regarding bioavailable metals, two exceedances of the calculated PNEC for zinc were recorded and 25 copper PNEC exceedances were recorded. The environmental permit emission limit for petroleum hydrocarbons was not exceeded in groundwater.

Surface water was largely compliant with the relevant standards during 2023. Single exceedances of the MAC-EQS were recorded for cadmium and lead in surface waters. Exceedances of the respective AA-EQS were recorded within surface waters for cadmium and chromium. Nine exceedances of the copper PNEC and three exceedances of the zinc PNEC were recorded in surface water in 2023. The TPH environmental permit emission limit was not exceeded with respect to surface waters during 2023.

Consistent with the various potential sources of gases including the heterogeneous waste material, presence of free phase hydrocarbons, and organic-rich superficial deposits, methane and carbon dioxide have been recorded at variable concentrations during 2023.

Oil recovery will continue from the peripheral trench, sumps, and wells in 2024, where LNAPL is consistently measured at recoverable thicknesses. Continued monitoring will show the impact this has on the NAPL distribution and thickness.

Discussions are ongoing regarding the Closure and Aftercare Management Plan and the overall restoration proposals, including the proposed monitoring strategies. Until agreement is reached with NRW regarding overall restoration proposals and proposed monitoring strategies, the current regime of groundwater level, NAPL, groundwater quality, surface water quality and landfill gas monitoring will continue throughout 2024.
