WADZ	West Anglesey Demonstration Zone

1. INTRODUCTION

1.1. THE PURPOSE OF THIS DOCUMENT

1. This document is the Environmental Statement (ES) for the proposed Morlais Project (the Project). The Project is being developed by Menter Môn Morlais Limited (hereafter referred to as Menter Môn), the applicant, a not for profit social enterprise company. The Project will have a generating capacity of up to 240 MW of tidal generating capacity within the Morlais Demonstration Zone (MDZ).

2. Menter Môn has contracted Royal HaskoningDHV to undertake the Environmental Impact Assessment (EIA) for the Project. A full project description for the Project is provided in **Chapter 4, Project Description**.

3. The purpose of this ES is to document the assessment of potential significant environmental impacts resulting from the Project and to demonstrate that this assessment is robust and comprehensive. This ES highlights the key environmental issues associated with the Project and provides an unbiased assessment of their effects and their relative significance. This process has ensured that these effects are fully considered and where appropriate, mitigation has been integrated into the design of the Project.

4. This ES describes the findings of the assessment of the potential environmental impacts associated with the construction, operation, maintenance, repowering and decommissioning of the Project, including the onshore and offshore infrastructure.

5. This ES is produced in support of an application for a Marine Licence under the Marine and Coastal Access Act 2009 and a Transport and Works Act Order (TWAO) with deemed planning permission under the Transport and Works Act 1992 for the Project. **Chapter 2, Policy and Legislation** provides further detail on the requirements of each permission.

1.2. BACKGROUND

6. The Project is located within one of several marine energy demonstration zones located around the United Kingdom (UK) coast, which have been leased out by The Crown Estate in a bid to encourage and accelerate the marine energy industry. Each of the zones were identified because they offer appropriate marine energy potential and access to necessary infrastructure, including ports and electricity grid. Environmental considerations were used in the process of determining the zone locations. The marine energy demonstration zones were incorporated into a plan level Habitats Regulations Assessment (HRA) before the leasing process was finalised and seabed agreements signed (ABPmer, 2014). The Project is located within the West Anglesey Demonstration Zone (WADZ), a zone primarily selected for its tidal resource.

7. Menter Môn Cyf (which established Menter Môn Morlais Limited as a Special Purpose Vehicle (SPV) for the development of the Project) has been appointed as the manager of the WADZ by The Crown Estate; however, Menter Môn Cyf fulfils an enabling role for the Project and does not act as a technology developer. For simplicity, no distinction between Menter Môn Cyf and Menter Môn Morlais Limited is made from this point in the ES. In this ES, the WADZ is referred to as the MDZ.

8. Two scoping reports were previously submitted to Natural Resources Wales (NRW), the Marine Management Organisation (MMO) and the Isle of Anglesey County Council (IoACC) in support of earlier (lower capacity) versions of the Project. However, since those reports were submitted the proposed installed capacity of the Project has been increased in response to industry demand and the project is now seeking consent for up to 240 MW capacity.

9. A further request for scoping opinion, for the current 240 MW capacity Project, was submitted to the Welsh Government and NRW in April 2018, superseding the earlier scoping requests. The Welsh Government and NRW provided a detailed scoping opinion, which has been the starting point for consultation on the project. Consultation with the Welsh Government and NRW has been ongoing throughout the EIA to discuss developments in the Project, scope and design parameters, and to agree methodologies and approaches used for environmental surveys and assessments during the EIA process (see **Chapter 6, Consultation**).

1.2.1. Need for the Project and Potential Benefits

10. Climate change is a global issue as a result of carbon emissions released into the atmosphere due to human activity. Generating and harnessing energy from low carbon, renewable sources such as tidal energy is one of the solutions available to substantially reduce carbon emissions, whilst answering the challenges of meeting energy demand as part of a balanced energy portfolio. The UK has an ambitious target of reducing greenhouse gas emissions by 57 % relative to 1990 levels by 2030, and by 80 % by 2050. In 2018, more than 50 % of the UK's electricity was generated by low carbon sources (Imperial College London, 2019). Targets for CO_2 reduction and the use of renewable energy sources are discussed further in **Chapter 2, Policy and Legislation**.

11. In its 2010 Energy Policy Statement, the Welsh Government set out aspirations to reach 22.5 Gigawatt (GW) of installed capacity from renewable energy technologies in Wales by 2020/25 (Welsh Assembly Government, 2010). The Environment (Wales) Act 2016 requires Welsh Government to reduce greenhouse gas emissions in Wales by at least 80 % by the year 2050. Since the passing of the Environment (Wales) Act, guided by the Well-Being of Future Generations Act 2015, the Welsh Government has set targets and provided additional support for renewable energy.

12. In March 2019, the Welsh Government published a new Low Carbon Plan, which aims to reach targets to deliver clean growth, protect the environment and ensure a healthier society for future generations (Welsh Government, 2019). The Environment (Wales) Act 2016 requires Welsh Ministers to set five yearly carbon budgets and the Low Carbon Plan details how Wales aims to meet the first carbon budget (2016 to 2020), with the second carbon budget to be published in 2021. Achieving a low carbon pathway for Wales ensures maximisation of the seven national well-being goals and the Welsh Government's well-being objectives. The Project would present a significant proportion of the Welsh carbon budgets (further detail on renewable energy policy is presented in **Chapter 2, Policy and Legislation**).

13. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the Welsh National Marine Plan (WNMP). A draft version has been issued for consultation with the aim of publishing the document in summer 2019. The draft Welsh National Marine Plan also sets out support for marine renewable energy generation where the

development of technologies, proposals for renewable energy generation and collaboration between sectors to understand the opportunities for renewable energy are encouraged. Full details of the draft WNMP are set out in **Chapter 2, Policy and Legislation**, and although not yet implemented consideration is given to the WNMP in each marine technical chapter (**Chapters 7** to **16**).

14. Tidal energy is a clean, renewable and highly predictable source of energy. The European Union (EU) has identified tidal energy, and more widely ocean energy (tidal and wave combined), as having the potential to contribute significantly to climate change reduction, socio-economic and energy security objectives. In 2014, the European Commission presented its action plan for achieving the potential for 'blue energy' by 2020 and beyond, aimed at facilitating the further development of the renewable ocean energy sector in Europe.

15. The Project, allowing long-term commercial demonstration of different technologies and small arrays of tidal devices, is an important step in developing the tidal energy industry within the UK and internationally, with significant potential socio-economic benefits (see **Chapter 25, Socioeconomics, Tourism and Recreation**) as well as contributing towards the reduction of greenhouse gas emissions and greater security of energy supply.

1.2.2. Morlais Objectives – Meeting Local Needs

16. Menter Môn's objectives for the Project are detailed in **Section 1.2.5** below. Key is local economic growth, including the potential for job creation. The design of much of the Project infrastructure will be undertaken with a view to maximising local content and developing locally based skills, with social value (including sub-contracts) an important consideration in the procurement strategy. During development of the procurement strategy, efforts will be made to identify local suppliers and contractors who could undertake each contract.

1.2.3. UK Tidal Resource

17. It is estimated that the UK has approximately 50 % of Europe's tidal energy resource (Department for Business, Energy and Industrial Strategy, 2013). Wave and tidal stream energy has the potential to meet up to 20 % of the UK's electricity demand, representing a 30 to 50 GW potential installed capacity (Department for Business, Energy and Industrial Strategy, 2013). However, the number of sites with sufficient tidal velocity to allow commercial exploitation is limited, with the MDZ being located within an area of high resource. The tidal resource in the MDZ is presented in **Chapter 7, Metocean Conditions and Physical Processes**.

1.2.4. The Project

18. Development of the MDZ is being led by Menter Môn who have been allocated funding from EU Structural Funds prioritised for marine energy in Wales.

19. The development of the Project will provide a consented tidal technology demonstration zone, specifically designed for the installation and commercial demonstration of multiple arrays of tidal energy devices. The Project will include permanent communal infrastructure for tidal technology developers which provides a shared route to a local grid connection via up to nine export cable tails, an onshore landfall substation at Ty Mawr, and an onshore electrical cable route to a grid connection substation at Orthios via a switchgear building at Parc Cybi.

20. The consented footprint of the Project will also include a design envelope for tidal devices for which the deployment is allowed under the consent, and the key parameters of which will encompass a range of currently available tidal devices, as well as seeking to anticipate the parameters of future technology.

21. Development of the Project will support those objectives of the 2017 Anglesey and Gwynedd Joint Local Development Plan, aimed at promoting the development of renewable or low carbon energy technologies (Isle of Anglesey County Council and Gwynedd Council, 2017). The Project will prioritise maximising opportunities for local communities directly via employment and indirectly via the establishment of a local supply chain.

22. The Project will have an installed capacity of up to 240 MW, enough to provide electricity to the equivalent of over 188,000[1] homes.

23. The Project will provide the supporting electrical infrastructure to connect tidal energy converters (TECs) within the MDZ and export the electricity generated to grid. The Project aims to secure a broad consent envelope, which will encompass a range of tidal device types and technologies with the potential to be installed and operated as part of the Project. The final details of all equipment to be installed, including tidal devices, will be confirmed following consent.

24. The EIA assesses the potential significant environmental impacts for the following project elements, during the construction, operation and maintenance, repowering and decommissioning phases of the Project life cycle (see **Chapter 4, Project Description**):

- **Offshore Development Area**
  - Tidal devices, incorporating:
    - Foundations or anchors;
    - TECs;
    - Supporting structures holding TECs in place in the water and connecting to foundations or anchors; and
    - Seabed preparation for foundations and anchors if necessary.
  - Possible use of electrical hubs or connectors as a way of connecting electrical cables from multiple tidal devices to electrical export cables;
    - Inter-array cables and cable protection;
    - Export cables and cable protection;
- **Onshore Development Area**
  - Landfall works including transition pits;

[1]Calculated taking the number of installed megawatts (240 MW) multiplied by the number of hours in one year (8,766 hours), multiplied by an expected load factor for tidal stream (35 %), divided by the average household energy consumption (3,900 kWhr), giving an equivalent of 188,806 homes.

  - Landfall substation at Ty Mawr (hereafter referred to as the Landfall Substation);
  - Cable installation from landfall to Landfall Substation;
  - Switchgear building at Parc Cybi (hereafter referred to as the Switchgear Building);
  - Grid connection substation at Orthios (hereafter referred to as the Grid Connection Substation);
  - Cable installation from Landfall Substation to Grid Connection Substation, via the Switchgear Building, including cable junction pits;
  - Temporary road and right of way closures;
- Temporary laydown and construction areas, including fencing / walls, and accommodation;
- Levelling works; and
- Parking areas (including electric vehicle charging points) and site access.

25. The infrastructure outlined above will be located within two development areas, as follows:

- Offshore Development Area (OfDA): including all intertidal and offshore areas where offshore infrastructure may be placed and encompassing the MDZ and the export cable corridor. The Offshore Development Area is shown in **Figure 1-1 (Volume II)**; and
- Onshore Development Area (ODA): including all intertidal and onshore areas where onshore infrastructure may be placed. The Onshore Development Area is shown in **Figure 1-2 (Volume II)**.

26. From the arrays of tidal devices, electricity will flow via subsea inter-array cables to an offshore hub or other connection point(s), from where subsea export cables will connect to export cable tails in the nearshore, with the export cable tails continuing to landfall.

27. On reaching shore the export cable tails will be joined to underground onshore cables via an underground transition pit, near to the point of landfall. The onshore underground cables will connect to a landfall substation, and from that substation, will connect via underground onshore cables and a switchgear building to a grid connection substation and grid connection.

28. A Front-End Engineering Design (FEED) study was undertaken by ITP Energised (ITPE) on behalf of Menter Môn in 2018, to provide the proposed design of the project necessary to inform the EIA project description for consent (**Appendix 4.1, Volume III**). Further to a revision of proposed installed project capacity to 240 MW, an addendum to the study was undertaken for the offshore infrastructure elements (**Appendix 4.2, Volume III**) by ITPE. In parallel, Black and Veatch Ltd. (B&V) have been responsible for further design of, and updates to, the onshore infrastructure within the ODA.

29. As a pre-consented and grid connected commercial demonstration zone, a number of different tidal devices and array configurations may be deployed at the Project over its anticipated 37-year lifetime, including construction and operation. The types of devices that have been used to define the Project Design Envelope (PDE) for the project are discussed in **Chapter 4, Project Description**.

1.2.5. The Developer

30. The Project's developer and the applicant for consent is Menter Môn. Menter Môn is a not for profit, third sector social enterprise, delivering socioeconomic development projects across North Wales. Menter Môn's motivation for the Project is to position itself as a community agency at the centre of renewable innovation, and to establish Anglesey as a marine energy hub, thereby securing maximum added value for the local economy and community.

31. Menter Môn has identified the following Project objectives;

- Generation of long-term financial income / resources for reinvestment in socio-economic and environmental projects to support the wider community;
- Development of locally based skills;
- Attracting investment to the area;
- Becoming a centre of excellence for tidal stream technologies;
- Providing a world class facility for tidal technology development;
- Preserving the environment; and
- Securing a sustainable energy supply for the area.

1.3. STRUCTURE OF THE ENVIRONMENTAL STATEMENT

32. The ES comprises three volumes:

- Volume 1: ES chapters (chapter list shown in **Table 1-1**);
- Volume 2: Figures; and
- Volume 3: Appendices.

33. A standalone Non-Technical Summary (NTS) is available which summarises the key characteristics of the Project and the findings contained within the ES.

1.4. KEY PROJECT TERMINOLOGY

34. The terminology presented in **Table 1-2** is used throughout the ES when describing the Project.

Table 1-2 Morlais Project Terminology

Applicant	Menter Môn Morlais Limited.
Array	A group of tidal devices connected to each other and to a common export cable.
Array Area	The area taken up by an array, including spaces between devices.
Array Export Cable	Export cable connecting an array of tidal devices to an export cable tail, and from there to grid via permanent infrastructure.
Berth	Discrete area of the Morlais Demonstration Zone identified for a specific tenant's array project demonstration.
Cable Protection	Protective materials strategically placed on sections of the export cable, export cable tails and inter-array cables, to hold them in place.
Code of Construction Practice	A document detailing the overarching principles of construction, contractor protocols, construction-related environmental management measures, pollution prevention measures, the selection of appropriate construction techniques and monitoring processes.
Cumulative effects	The combined effect of the Morlais Project in combination with the effects from a number of projects, on the same single receptor / resource.
Cumulative impact	Impacts that result from changes caused by other past, present or reasonably foreseeable actions together with the Morlais Project.
Device Area	Plan view surface area occupied by a tidal device.
Device Type	A grouping of tidal devices, with similar characteristics. For example, grouping on the basis of the nature of the Tidal Energy Converter (TEC) technology or grouping on the basis of the location and scale of the tidal device during operation, without consideration of the type of TEC deployed.
Effect	Term used to express the consequence of an impact. The significance of an effect is determined by correlating the magnitude of the impact with the importance, or sensitivity, of the receptor or resource in accordance with defined significance criteria.

Environmental Impact Assessment (EIA)	A statutory process by which certain planned projects must be assessed before a formal decision to proceed can be made. It involves the collection and consideration of environmental information, which fulfils the assessment requirements of the EIA Directive and EIA Regulations, including the publication of an EIA Report.
Export Cables	Up to nine lengths of cable from arrays within the Morlais Demonstration Zone (MDZ), connected to the export cable tails.
Export Cable Corridor	The corridor within which the export cables and export cable tails will be routed from the Morlais Demonstration Zone site to the landfall location at Abraham's Bosom.
Export Cable Tails	Up to nine lengths of cable installed from the transition pit in the landfall area, to a point in the nearshore offshore seabed via Horizontal Directional Drilling (HDD) or trenching.
Footprint	The surface area of a tidal device that is in physical contact with the seabed.
Grid Connection Substation	Grid connection substation at Orthios.
Horizontal Directional Drilling (HDD)	A method of cable installation where the cable is drilled beneath a feature without the need for trenching.
Hub	Electrical infrastructure used to connect two or more tidal devices within an array.
Inter-Array Cables	Offshore cables which link the arrays to each other and the offshore electrical platforms, these cables will include fibre optic cables.
Joint Pits	Underground structures constructed at regular intervals along the onshore cable route to join sections of cable and facilitate installation of the cables into buried ducts within the road.
Landfall	The area (from Mean Low Water Springs) where the offshore export cables would make contact with land and connect to the onshore cables.
Landfall Substation	Landfall substation at Ty-Mawr.
Morlais Demonstration Zone (MDZ)	Defined by The Crown Estate Lease boundary, the area within which the tidal devices/arrays will be deployed along with associated infrastructure such as inter-array cables, export cables, marker buoys, site monitoring equipment and electrical connections to the export cables. An offshore area of 35km^2 within which the Project will deploy arrays of tidal devices and associated infrastructure.
Offshore Development Area (OfDA)	The combined area of the Morlais Demonstration Zone and the Export Cable Corridor.
Offshore Infrastructure	All offshore infrastructure including tidal devices, foundations or anchors, inter array cables, hubs, export cables, export cable tails and cable protection.
Onshore cables	The cables which take the electricity from the landfall transition pit to the grid connection substation.
Onshore Cable Corridor	The area within which the onshore cables and associated infrastructure such as joint bays, will be located.
Onshore Development Area (ODA)	The area including the intertidal landfall location at Abraham's Bosom, the short onshore cable route between landfall and the landfall substation infrastructure (up to and including landfall substation/control room), and the onshore cable route to the grid connection substation. This area is larger than the order limits proposed within the Transport and Works Act Order.
Project Design Envelope (PDE)	The parameters within which the potential maximum extent of the project in terms of materials, scale, time and location can be described. Sometimes referred to as the 'Rochdale envelope'.
Repowering	The removal of a tenant's infrastructure at the end of a demonstration period and replacement with new tenant infrastructure.

Safety Zones	A marine area declared for the purposes of safety around a renewable energy, installation or works / construction area under the Energy Act 2004, the Electricity (Offshore Generating Stations) (Safety Zones) (Application Procedures and Control of Access) Regulations 2007 and Transport and Works Act Order.
Substation	A compound containing electrical equipment to enable connection to the existing electricity network. This also contains equipment to help maintain stable grid voltage.
Subzone	A part of the Morlais Demonstration Zone, within which defined types of tidal device may be deployed.
Swept Area	The cross-sectional area of the Tidal Energy Convertor perpendicular to the current flow.
Switchgear Building	Switchgear building at Parc Cybi.
Tenant / developer	A company or organisation which reaches agreement with Menter Môn to deploy tidal devices within the Morlais Demonstration Zone.
Tenant infrastructure	Tidal devices, hubs, inter array cables, cable protection, monitoring platforms / buoys and marker buoys.
Tidal Device	One complete unit including: Tidal Energy Convertor(s) (i.e. rotors and nacelle), foundations, support structure.
Tidal Energy Convertor (TEC)	A device that convert kinetic and potential energy contained within moving tidal water into electricity.
Transition Pit	Underground structures at the landfall and grid connection substation that house the joints between trenched and trenchless export cable sections.
Under-keel clearance	The vertical distance between the deepest underwater point of a vessels hull and the shallowest point of seabed or of an underwater structure.
Visually prominent	A tidal device where the large proportion of the support structure is visible above the water to the extent it is visually prominent, together with ancillary elements such as navigation lights, railings and mast

1.5. EIA PROJECT TEAM

35. Royal HaskoningDHV, in collaboration with MarineSpace, has been commissioned to undertake the EIA, providing consenting and licensing support to Menter Môn.

36. Royal HaskoningDHV has extensive experience in renewable energy EIA and a detailed understanding of the potential impacts of wave and tidal devices, having taken the lead EIA role for the following projects: the SeaGen project, Strangford Lough (tidal); the Kyle Rhea array project (tidal), the Sound of Islay (tidal) array project, the Lewis array (wave) project; and Perpetuus Tidal Energy Centre (tidal). As a company, Royal HaskoningDHV is an accredited member of the Institute for Environmental Management and Assessment (IEMA) and registrant of the EIA Quality Mark, which provides a benchmark for EIA activities and allows demonstration of commitment to effective practice. Royal HaskoningDHV has used in-house experts in the following areas to compile this ES: terrestrial archaeology; hydrology; geology; water quality; coastal processes; terrestrial ecology; marine mammals; ornithology; air quality; traffic and transport and onshore noise.

37. MarineSpace is a specialist marine consultancy and has supported a range of projects including providing consultancy support to Tidal Energy Limited (TEL) on its Ramsey and St David’s Head projects and consenting support to Tidal Lagoon Power Ltd (TLP) in developing the Adaptive Environmental Management Plan (AEMP) for the Swansea Bay Tidal Lagoon project. MarineSpace has used in-house experts in the following areas to compile this ES; benthic and intertidal ecology, fish ecology and fisheries, marine archaeology, and navigation.

38. External expertise has been sourced from the following subcontractors:

- Partrac Limited – geophysical survey;
- BSG Ecology – ecological survey;
- Ocean Ecology Limited – benthic survey;
- Wessex Archaeology – terrestrial archaeological survey and desk-based assessment;
- Marico Marine – navigational risk assessment and navigation survey;
- Anatec – navigation survey;
- Aquaterra – socio-economics, tourism and recreation impact assessment;
- Axiom Traffic Ltd. – road traffic survey;
- Wynns Ltd. – Abnormal Indivisible Load; and
- SLR Consulting, with support from Hepla – seascape and landscape visual impact assessment.

39. Public consultation support and management of the public consultation record has been provided by Ateb.

2. POLICY AND LEGISLATION

2.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) identifies the key National and European legislative and policy drivers and commitments in areas of climate change and renewable energy, which are relevant to the Morlais Project (the Project). It also outlines the key consenting legislation and planning policy (both national and local) under which consent for the Project would be delivered. The technical chapters (**Chapters 7 to 26**) outline any legislation which is specific to the relevant receptors.

2. The Project aims to:

- Generate long-term financial income / resources for reinvestment in socio-economic and environmental projects to support the wider community;
- Develop locally based skills;
- Attract investment to the area;
- Become a centre of excellence for tidal stream technologies;
- Provide a world class facility for tidal technology development;
- Preserve the environment; and
- Secure sustainable energy supply for the area.

2.2. POLICY BACKGROUND

2.2.1. Climate Change and Renewable Energy

3. Climate change is one of the greatest environmental challenges facing the world today, with increasing pressure to reduce carbon emissions as a way of mitigating predicted increases in average global temperatures. As a result, climate change and reducing the rate of global warming is a key driver behind the continued development of the renewable energy industry. A summary of relevant climate change policies is provided in **Table 2-1**.

4. The UK is currently a member of the G7 (formerly the G8) and plays a leading role in tackling climate change at an international level. Whilst the UK remains within the European Union (EU), the UK is obliged to continue to meet its commitments to reducing climate change. Through the Kyoto Protocol (1997) and the Paris Climate Agreement (2015), the UK has a legally binding target to reduce emissions of greenhouse gases. The Environment (Wales) Act 2016 sets target to reduce emissions by at least 80 % by 2050 and provides the legislative framework for establishing a carbon budgeting approach in Wales. Since the passing of the Environment (Wales) Act, guided by the Well-Being of Future Generations Act 2015, the Welsh Government has set targets and provided additional support for renewable energy.

5. In March 2019, the Welsh Government published a new Low Carbon Plan, which aims to reach targets to deliver clean growth, protect the environment and ensure a healthier society for future generations (Welsh Government, 2019). The Environment (Wales) Act 2016 requires Welsh Ministers to set five yearly carbon budgets and the Low Carbon Plan details how Wales aims to

meet the first carbon budget (2016 to 2020), with the second carbon budget to be published in 2021. Achieving a low carbon pathway for Wales ensures maximisation of the seven national well-being goals and the Welsh Government's well-being objectives.

6. The Climate Change Act 2008 also formally commits the UK to reduce its carbon emissions by at least 80 % by 2050, in line with commitments under the Kyoto Protocol. In order to achieve this, the UK Government sets carbon budgets to benchmark the reductions. Currently targets are to reduce carbon emissions by 37 % below 1990 levels in the period 2018-2022. The forward planning targets are for a 51 % reduction (below 1990 levels) in greenhouse gases by 2025 and a 57 % reduction by 2030 (Committee on Climate Change, 2018).

7. Renewable energy is seen as a primary method of reducing emissions of greenhouse gases, in particular CO_2. The UK has implemented the EU Renewable Energy Directive (Directive 2009/28/EC) into UK law, primarily through the Promotion of the Use of Energy from Renewable Sources Regulations 2011, to deliver national targets and priorities in greenhouse gas reductions as well as our domestic targets of reducing greenhouse gas emissions by 80 % by 2050 (HM Government, 2011).

8. In addition to the reduction in greenhouse emissions, renewable energy is an important element in working towards a more varied energy mix and increased energy security to insulate the UK against global fluctuations in energy prices. Currently, renewable energy generation has been able to provide up to 24 % of the UK's energy requirements during periods of optimum conditions. The renewable energy industry has also been an important economic driver helping to create direct and indirect jobs and benefit the wider economy.

9. Specific measures for renewable energy were set out in the UK Renewable Energy Strategy (RES) which was published in parallel with the UK Low Carbon Transition Plan in July 2009 (HM Government, 2009a; HM Government, 2009b).

10. The RES sets out the path by which the UK can meet the legally-binding target of 15 % energy consumption from renewable sources by 2020. The UK interim target was for 5.4 % of energy consumption to be provided by renewable energy by 2013. Preliminary calculations indicate that this target was met.

11. The Renewable Energy Roadmap (DECC, 2011a; DECC, 2012; DECC, 2013) updated some of the aims within the RES and identifies eight types of technology capable of providing 90 % of the renewable energy required to meet the UK's 2020 target of 15 % of energy consumption derived from renewable sources. It reports that energy from tidal stream devices could make a significant contribution to meeting the UK future energy needs.

Table 2-1 Summary of Relevant Climate Change Legislation

Policy	Summary
United Nations Framework Convention on Climate Change (Paris Climate Agreement)	▪ Limit global temperature increase to below 2 °C, while pursuing efforts to limit the increase to 1.5 °C; ▪ Commitments by all parties to prepare, communicate and maintain a Nationally Determined Contribution; and

Policy	Summary
	▪ In 2023, and every five years thereafter, a global stocktake will assess the collective progress towards meeting the purpose of the Agreement.
European Union Renewable Energy Directive	▪ A reduction of 20 % in greenhouse gases by 2020 (below 1990 levels); and ▪ 20 % of the total EU energy (electricity, heat and fuel) consumption to come from renewable sources by 2020.
The Environment (Wales) Act 2016	▪ A reduction of 80 % in greenhouse gases by 2050; and ▪ Welsh Ministers must set interim emissions targets for 2020, 2030 and 2040, together with 5-year carbon budgets for the periods 2021-2025 and 2026-2030.
The UK Climate Change Act 2008	▪ A reduction of 34 % in greenhouse gases by 2020 (below 1990 levels); and ▪ A reduction of 80 % in greenhouse gases by 2050 (below 1990 levels).
The UK Energy Act 2013	▪ Introduction of provisions to enable a statutory 2030 decarbonisation target range for the GB electricity sector; and ▪ Electricity Market Reform including introduction of the Contracts for Difference (CfDs) support mechanism.

2.2.2. Renewable Energy Policy Wales

12. Welsh renewable policy focuses on the transition to a low carbon energy system and maximising the benefits for both Wales and Welsh communities. The 2012 Welsh Government policy document, Energy Wales: A Low Carbon Transition, updated in 2016, outlines the Welsh Government's approach to utilising the marine environment for renewable energy deployment (Welsh Government, 2012b). Marine renewable energy has been identified as a key way of meeting renewable energy objectives, with an aim to capture 10 % of the potential tidal stream and wave energy off the Welsh Coastline by 2025.

13. The Welsh Government policy document sets out the Welsh goals for providing and encouraging growth of renewable energy generation within the energy mix whilst ensuring development is pursued in a socially, environmentally and economically responsible manner that is compliant with the policies outlined in the Welsh Government resource management paper; Sustaining a Living Wales (Welsh Government, 2012a).

14. The Welsh Government has outlined the Anglesey Energy Island Programme which sets out to promote Anglesey as a hub for energy developments such as the Minesto Holyhead Deep project, Wylfa B Nuclear Power Station and Holyhead Biomass Energy Centre (IoACC, 2010). Through this, the Welsh Government is aiming to maximise socio-economic benefits to Anglesey and the wider area. The Project, whilst not identified in the Programme, will help achieve this objective and is being developed to maximise local socio-economic benefits where possible.

15. The Welsh First Minister has also set up the Energy Wales Unit, who's remit is to build on the policies set out in the 2012 Policy document and focus on progressing marine energy.

2.3. CONSENTING REGIME

16. The Project will be authorised via the following principal consents:

- A Transport and Works Act Order under the Transport and Works Act 1992; and
- A Marine Licence under the Marine and Coastal Access Act 2009 (MCAA).

17. The following is proposed to be authorised through the Transport and Works Act Order:

- The establishment of Marine Safety Zones;
- Public Rights of Way temporary closures; and
- The carrying out of street works.

18. Deemed planning permission will be granted with the Transport and Works Act Order.

19. The following is proposed to be addressed via the Marine Licence:

- Marine Disposal Sites.

20. Applications for consent to perform specific activities will also be made. These are likely to include, but not limited to:

- European Protected Species Licence (if required).

21. This ES presents the results of the EIA which will be submitted with the applications for consent.

2.3.1. Transport and Works Act 1992

22. The Transport and Works Act 1992 empowers orders to be made authorising the construction and operation of linear and other guided transport schemes and other types of infrastructure in England and Wales, including works that interfere with rights of navigation in waters up to the limits of the territorial sea provided that they will fall within a prescribed category of works; these include both offshore installations and utilities structures. The Department for Business, Energy and Industrial Strategy (BEIS) administers applications made under the Transport and Works Act 1992 in respect of energy-related projects in those UK territorial waters adjoining England; however, for developments adjacent to Wales, the National Assembly for Wales is the determining body.

2.3.2. Marine and Coastal Access Act 2009

23. The MCAA introduced a new system for marine planning in the marine and coastal environment in England and Wales. Under the MCAA, a Marine Licence is required for carrying out a 'licensable marine activity' in Welsh waters, including construction works on the seabed, depositing of any subject, dredging and aggregate extraction. The Welsh Government is the licensing authority for the Welsh inshore and offshore region; however, the Marine Licensing Team in NRW administers marine licenses on behalf of the Welsh Government.

24. The MCAA also provides the Welsh Government with the powers to introduce Marine Conservation Zones (MCZs) in the Welsh inshore area. The primary aim of MCZs is to deliver the Government's vision for an 'ecologically coherent network of MPAs across the UK and to

ensure the health of the wider UK marine environment'. In 2014, the first MCZ in Welsh waters was established, Skomer MCZ. These sites are intended to protect habitats and species not necessarily covered by existing mechanisms and complement the existing MPA network designated under the Habitats and Birds Directives (see **Section 2.4.3**).

2.3.3. Planning (Wales) Act 2015

25. The application for the Transport and Works Act Order will be accompanied by an application for deemed planning permission. The decision in respect of the application will have due regard to the requirements of the Planning (Wales) Act 2015.

26. The Planning (Wales) Act 2015 sets out the legislative changes to deliver reform of the planning system in Wales. The main objectives of the Planning (Wales) Act 2015 are to improve the existing planning process by producing a modernised framework for the delivery of planning services, strengthening the plan led approach, improving resilience, improving the development management system and enabling effective enforcement. The Planning (Wales) Act 2015 introduced a statutory framework for the planning system in Wales, and any statutory body carrying out a planning function must exercise those functions in accordance with the principles of sustainable development as set out in the Well Being of Future Generations (Wales) Act 2015 (see **Section 2.3.5**).

2.3.4. Wales Act 2017

27. The Wales Act 2017 introduces a new reserved powers model of devolution for Wales. The Wales Act 2017 makes the National Assembly a permanent part of the UK's political framework. As a result, the National Assembly will be able to legislate on anything not reserved to the UK Parliament. The Wales Act 2017 therefore devolves powers to the National Assembly and Welsh Government in areas including consenting for new energy projects. The Wales Act 2017 provides significant powers and responsibility to the Welsh Government over energy and environmental matters, including authorising planning permission for energy generating schemes up to 350 MW. Although the Wales Act 2017 came into force in 2017, whilst the powers rest with the Welsh Government, the framework for the majority of changes, including the exercise of the reserved powers model, is not yet in place.

2.3.5. The Well Being of Future Generations (Wales) Act 2015

28. The Wellbeing of Future Generations (Wales) Act 2015 promotes improvement of the social, economic, environmental and cultural well-being of Wales. The Wellbeing of Future Generations (Wales) Act 2015 places a statutory duty on public bodies in relation to sustainable development, based on seven well-being goals, outlined in **Table 2-2**.

29. Climate change is integral to the wellbeing goals, which recognise that the case for action on climate change is clear and fundamental to future prosperity and the future resilience of communities. The Wellbeing of Future Generations (Wales) Act 2015 provides a mechanism for public bodies to set targets and report progress against indicators. Through its well-being objectives, the Wellbeing of Future Generations (Wales) Act 2015 sets a clear agenda for sustainable development.

Table 2-2 Well-Being Goals and Adherence by the Project

Well-being Goal	Description	How is this addressed by the Project
A prosperous Wales	An innovative, productive and low carbon society which recognises the limits of the global environment and therefore uses resources efficiently and proportionately (including acting on climate change); and which develops a skilled and well-educated population in an economy which generates wealth and provides employment opportunities, allowing people to take advantage of the wealth generated through securing decent work.	If built, the Project would have a design life of approximately 37 years, after which it may be either decommissioned or repowered (subject to separate consenting). During its operation the project would contribute to reaching global, European and national targets on CO_2 reduction and renewable energy production. It is estimated that the Project could produce enough electricity each year to power the equivalent of over 188,000 houses. Further information on tidal energy is provided in **Chapter 1, Introduction**.
A resilient Wales	A nation which maintains and enhances a biodiverse natural environment with healthy functioning ecosystems that support social, economic and ecological resilience and the capacity to adapt to change (for example climate change).	The ES details the considerations of the Project on the baseline environment for a number of key receptors. A habitats regulations assessment (HRA) report has been compiled to inform the assessment as to whether the Project has the potential to have an adverse effect on the integrity and features of a Natura 2000 site. Where appropriate, mitigation measures are provided to ensure that no residual significant impacts are caused by the Project. The technical chapters (**Chapters 7** to **26**) outline any legislation which is specific to the relevant receptors. Information to support the HRA is provided in **Document MOR/RHDHV/DOC/0067, Information to Support HRA**.
A healthier Wales	A society in which people's physical and mental well-being is maximised and in which choices and behaviours that benefit future health are understood.	An assessment of the impacts of the project on Health and Socio-economics is provided in **Chapter 25, Socioeconomics, Tourism and Recreation**. The Project will have no significant negative impact on health and wellbeing, and is expected to have a minor beneficial impact to a number of receptors.
A more equal Wales	A society that enables people to fulfil their potential no matter what their background or circumstances (including their socio-economic background and circumstances).	An assessment of the impacts of the project on Socio-economics is provided in **Chapter 25, Socioeconomics, Tourism and Recreation**. The Project is being developed by Menter Môn Morlais Limited (hereafter referred to as Menter Môn). Menter Môn is a not for profit, third sector social enterprise, delivering socioeconomic development projects across North Wales. Menter Môn's motivation for the Project is to position itself

Well-being Goal	Description	How is this addressed by the Project
		as a community agency at the centre of renewable innovation, and to establish Anglesey as a marine energy hub, thereby securing maximum added value for the local economy and community.
A Wales of cohesive communities	Attractive, viable, safe and well-connected communities.	The developers of the Project have a strong local presence on Anglesey and are committed to developing renewable energy on the Island. The developers of the Project also have a desire to increase and diversify employment and economic development opportunities across the communities.
A Wales of vibrant culture and thriving Welsh language	A society that promotes and protects culture, heritage and the Welsh language, and which encourages people to participate in the arts, and sports and recreation.	Menter Môn is a welsh-speaking not for profit company providing solutions to the challenges facing rural Wales. The developer works with businesses, communities and individuals, to deliver meaningful projects, that harness their strengths and contribute to a sustainable future. Menter Môn embrace and recognise the value of our resources and seek to add value for the benefit of the community. These include natural and built environment, cultural heritage, agricultural and food sectors and most importantly the Welsh people. Copies of the Morlais Non-Technical Summary (NTS) and the Transport and Works Act Order are available in Welsh.
A globally responsible Wales.	A nation which, when doing anything to improve the economic, social, environmental and cultural well-being of Wales, takes account of whether doing such a thing may make a positive contribution to global well-being.	The Project seeks to provide a platform for commercial tidal energy device development, the first of this scale in the world. Evidencing the Projects importance, the development phase has been supported by the European Regional Development Fund.

2.3.6. Maritime Spatial Planning Directive

30. The Maritime Spatial Planning Directive (EU Directive 2014/89) (MSPD) has been in effect since September 2014. The Directive requires EU countries to draw up maritime spatial plans no later than 31st March 2021. These plans will enable public authorities to organise human activities in marine areas ensuring efficiency and sustainability of ecological, economic and social objectives.

31. Draft Resource Areas (RA) and Strategic Resource Areas (SRA) are identified within the draft Welsh National Marine Plan (WNMP) currently under preparation. RAs are broad areas that describe the distribution of a particular resource that has the potential to be used or is used by certain marine sectors, e.g. aggregates, aquaculture or marine energy. SRAs are used to further allocate space and focus future use of the Welsh inshore and offshore areas. These are areas of good opportunity for future use by a particular sector over the plan period and beyond. SRAs lie within the related RA. SRAs have been identified at a broad scale; local issues and

constraints that relate to the general policies that have a spatial dimension will be taken into account when considering individual proposals. As laid out in the WNMP, the Project is located within a SRA identified for Tidal Stream Energy.

2.3.7. National Policy Statements

2.3.7.1. National Policy Statement

32. The Project is seeking consent for a Transport and Works Act Order from the Welsh Ministers and a Marine Licence from Natural Resources Wales (NRW). Although this Project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts on marine water and sediment quality for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to marine water and sediment quality include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011b); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011 (DECC, 2011c).

33. The NPS for renewable energy infrastructure (EN-3) does not cover other types of renewable energy generation that are not at present technically viable over 50MW onshore or over 100MW offshore such as schemes that generate electricity from tidal stream or wave power. It is expected that tidal range schemes may be the subject of applications to the IPC within the near future (DECC, 2011c).

2.3.7.2. Marine Policy Statement

34. The Marine Policy Statement (MPS) adopted by all UK administrations in March 2011 provides the policy framework for the preparation of marine plans and establishes how decisions affecting the marine area should be made in order to enable sustainable development. The MPS sets out a vision of having ‘clean, healthy, safe, productive and biologically diverse oceans and seas’ by supporting the development of Marine Plans.

35. The MPS states that “*Marine based activities can provide opportunities for employment in long established industries such as…offshore electricity transmission. This employment provides wide and long-term benefits for both national and local economies*.”

36. Furthermore, it is expected that “*Wave and tidal stream technologies also have significant potential in the medium to long-term*”. The MPS estimated that up to 20 % of the UK’s current energy demand could be supplied by wave and tidal energy.

37. The MPS states that “*It is important for marine planning to take account of appropriate locations for such developments alongside more established uses of marine space and to recognise the timescales and stages against which the sector is likely to progress, including the lead time for grid and infrastructure development. For example, pre-commercial demonstration deployments will need to manage the potential environmental impacts in relation to the scale of risks and*

legislative requirements while recognising that not all uncertainties can be addressed in the early life of this technology."

38. The document suggests to developers that adaptation and mitigation methods for these technologies may be supported by detailed monitoring programmes and co-ordinated research initiatives, including post deployment of devices. This approach is being followed by Menter Môn, with the intention to supply a detailed construction and operation monitoring and mitigation plan.

39. All public authorities are to take into account the MPS and relevant Marine Plans when making decisions in regard to the marine area. This ensures that marine resources are used in a sustainable way in line with the high-level marine objectives.

2.3.7.3. Welsh National Marine Plan

40. By adopting the MPS, the Welsh Government committed to the requirement to introduce Marine Plans for Wales. The Project adheres directly to the vision for the Welsh inshore and offshore marine planning region, which states that during the 20-year plan period the Welsh Government will ensure that "*Through the responsible deployment of low carbon technologies, the Welsh marine area is making a strong contribution to energy security and climate change emissions targets*".

41. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the WNMP. The WNMP is being developed in accordance with the MCAA, the MPS and the MSPD. A draft version has been issued for consultation with the aim of publishing the document in summer 2019.

42. Until the WNMP comes into effect, the MCAA, MPS and MSPD will be adhered to and the guidance within the draft WNMP has been referred to within this section.

43. The Project falls within the supporting sector policy 'ELC_01: Low carbon energy (supporting)', as detailed within the draft WNMP. The draft WNMP states that "*Proposals for all types of marine renewable energy generation (wind, tidal and wave energy) and associated infrastructure are strongly encouraged, especially: a) in corresponding wave, tidal stream and any other defined renewable energy technology test and demonstration zones; and b) in corresponding wave, tidal stream and tidal lagoon Strategic Resource Areas. Relevant public authorities should, in liaison with the sector and other interested parties, collaborate to understand opportunities for the sustainable use of: a) renewable energy Strategic Resource Areas; and b) wider natural resources that provide renewable energy potential in order to support the sustainable growth of the renewable energy sector through marine planning".*

44. The draft WNMP contains the policies in **Table 2-3** which are particularly relevant to the Project.

Table 2-3 WNMP Policies Relevant to the Project

Policy	Details	Where this is considered within the ES
ECON_01: Blue growth	Proposals for economically sustainable activities are encouraged, particularly where they contribute to: ▪ a more resilient economy; ▪ employment opportunities particularly for coastal communities; ▪ generating wealth; ▪ allowing people to take advantage of the wealth; ▪ protecting and creating employment at all skill levels; ▪ maintaining communities with a high-density of Welsh speakers; ▪ tackling poverty by supporting deprived coastal communities; and / or ▪ the sustainable management of natural resources thereby supporting ecosystem resilience.	Chapter 1, Introduction and Chapter 25, Socioeconomics, Tourism and Recreation
SOC_02: Well-being of coastal communities	Proposals that contribute to the well-being of coastal communities are encouraged.	Chapter 25 Socio-economics, Tourism and Recreation
SOC_05: Historic assets	Proposals should demonstrate how potential impacts on historic assets and their settings have been taken into consideration at an early stage and should, in order of preference: a) avoid adverse impacts on historic assets and their settings; and/or b) minimise impacts where they cannot be avoided; and/or c) mitigate impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Opportunities to enhance historic assets are encouraged.	Chapter 13 Offshore Archaeology and Cultural Heritage Chapter 20 Onshore Archaeology and Cultural Heritage Chapter 24 Seascape, Landscape and Visual Impact Assessment
SOC_06: Designated landscapes	Proposals that demonstrate that they are compatible with the purposes and special qualities for which National Parks or Areas of Outstanding Natural Beauty have been designated are encouraged.	Chapter 24 Seascape, Landscape and Visual Impact Assessment
SOC_07: Seascapes	Proposals should demonstrate how potential impacts on seascapes have been taken into consideration at an early stage and should, in order of preference: a) avoid adverse impacts on seascapes; and/or b) minimise impacts where they cannot be avoided; and/or c) mitigate impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Opportunities to enhance seascapes are encouraged.	Chapter 24 Seascape, Landscape and Visual Impact Assessment
SOC_12: Support for wider resilience to climate change	Relevant public authorities should support opportunities that contribute towards climate change adaptation and/or mitigation	Chapter 2 Policy and Legislation

Policy	Details	Where this is considered within the ES
ENV_05: Underwater Noise	Proposals should demonstrate that they have considered man-made noise impacts on the marine environment and, in order of preference: a) avoid adverse impacts; and/or b) minimise impacts where they cannot be avoided; and/or c) mitigate impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding	Chapter 9 Benthic and Intertidal Ecology, Chapter 10 Fish and Shellfish Ecology, Chapter 12 Marine Mammals, Chapter 14 Commercial Fisheries
ENV_06: Air and Water Quality	Proposals should demonstrate that they have considered their potential air and water quality impacts and should, in order of preference: a) avoid adverse impacts; and/or b) minimise adverse impacts where they cannot be avoided; and/or c) mitigate adverse impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding.	Chapter 8 Marine Water and Sediment Quality, Chapter 22 Air Quality
ELC_01: Low carbon energy (supporting)	Proposals for all types of marine renewable energy generation (wind, tidal and wave energy) and associated infrastructure are strongly encouraged, especially: a) in corresponding wave, tidal stream and any other defined renewable energy technology test and demonstration zones; and b) in corresponding wave, tidal stream and tidal lagoon Strategic Resource Areas. Relevant public authorities should, in liaison with the sector and other interested parties, collaborate to understand opportunities for the sustainable use of: a) renewable energy Strategic Resource Areas; and b) wider natural resources that provide renewable energy potential in order to support the sustainable growth of the renewable energy sector through marine planning.	Chapter 1 Introduction, Chapter 3 Site Selection and Consideration of Alternatives and Chapter 4 Project Description
GOV_01: Cumulative effects	Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	Chapter 26, Cumulative Impact Assessment

45. The WNMP outlines the following aspects that Menter Môn should be undertaking to ensure that the Project is in accordance with the plan:

- Engage early across and between relevant stakeholders;
- Apply the general cross-cutting and sector-specific policies set out in this plan to guide proposals;
- Consider the potential beneficial and adverse impacts of their proposed activity on the economy, society and the environment; minimise adverse effects and maximise opportunities for coexistence and securing multiple benefits;
- Supply the information required for the relevant public authorities to assess their proposal(s) including fit with relevant planning policy; and
- Ensure that evidence provided is sound and proportionate given the development in question and its associated risks.

46. Each of the above has been provided throughout the EIA process (**Chapter 5, EIA Methodology**).

2.3.7.4. Planning Policy Wales

47. Planning policy for Wales is set out in the document Planning Policy Wales (Welsh Government, 2018). The planning policy document outlines the Welsh Government's approach to ensuring that the planning system contributes to the delivery of sustainable development and improves the social, economic, environmental and cultural well-being of Wales, as required by the Planning (Wales) Act 2015 and the Well-Being of Future Generations (Wales) Act 2015.

48. The Planning Policy also takes into consideration meeting the aims of Sustaining a Living Wales document to ensure that development does not take precedence over and impact on other factors. The policy encourages a positive approach to the development of renewable and low carbon energy development and encourages collaboration where possible.

49. The Project falls within the following Planning Policy Wales key planning principles:

- Growing Our Economy in a Sustainable Manner;
- Making Best Use of Resources;
- Facilitating Accessible and Healthy Environments;
- Creating and Sustaining Communities; and
- Maximising Environmental Protection and Limiting Environmental Impact.

50. The following Planning Policy Technical Advice Notes (TAN) have been reviewed within the relevant chapters of the ES:

- TAN 5: Nature Conservation and Planning;
- TAN 8: Renewable Energy;
- TAN 11: Noise;
- TAN 12: Design;
- TAN 13: Tourism;
- TAN 14: Coastal Planning;

- TAN 15: Development and Flood Risk;
- TAN 18: Transport;
- TAN 21: Waste;
- TAN 23: Economic Development; and
- TAN 24: The Historic Environment

2.3.8. Regional Plans

2.3.8.1. Anglesey and Gwynedd Joint Local Development Plan (JLDP)

51. Development of the Project will support those objectives of the 2017 Anglesey and Gwynedd Joint Local Development Plan, aimed at promoting the development of renewable or low carbon energy technologies. The project will prioritise maximising opportunities for local communities directly via employment and indirectly via the establishment of a local supply chain.

52. Of the policies contained in the JLDP, those presented in **Table 2-4** are considered to be of particular relevance to the Project.

Table 2-4 Relevant Policies of the Anglesey and Gwynedd JLDP

Policy	Description	Where considered within the ES
Strategic Policy PS 1: Welsh Language and Culture	Promote and support the use of the Welsh language in the Plan area.	Menter Môn are a welsh-speaking company. Copies of the NTS and the draft Transport and Works Act Order are available in Welsh.
Strategic Policy PS 2: Infrastructure and Developer Contributions	New development to ensure sufficient provision of essential infrastructure (either on-site or to service the site) is either already available or provided in a timely manner to make the proposal acceptable.	**Chapter 3, Site Selection and Consideration of Alternatives** **Chapter 4, Project Description**
Policy ISA 1: Infrastructure Provision	Proposals will only be granted where adequate infrastructure capacity exists or where it is delivered in a timely manner.	
Policy TRA 2: Parking Standards	Parking provision for all modes of transport should be in accordance with the Councils' Parking Standards.	Parking, traffic and transport impacts during construction and operation are outlined within **Chapter 23, Traffic and Transport**.
Policy TRA 4: Managing Transport Impacts	Where appropriate, proposals should be planned and designed in a manner that promotes the most sustainable modes of transport	
Strategic Policy PS 5: Sustainable Development	Development will be supported where it is demonstrated that they are consistent with the principles of sustainable development	The nature of the Project is to alleviate the causes of climate change and develop low carbon technologies.

Policy	Description	Where considered within the ES
Strategic Policy PS 6: Alleviating and Adapting to the Effects of Climate Change	Proposals will only be permitted where it is demonstrated that they have fully taken account of the energy hierarchy and reducing greenhouse gas emissions	**Chapter 4, Project Description**
Policy PCYFF 1: Development Boundaries	Proposals within Development Boundaries will be approved in accordance with the other polices and proposals of this Plan, national planning policies	The Project considers the relevant Development Boundaries within the JLDP. All relevant local and national plans and policies are considered within **Chapter 2, Policy and Legislation**.
Policy PCYFF 2: Development Criteria	A proposal should demonstrate its compliance with: 1. Relevant policies in the Plan; 2. National planning policy and guidance	
Policy PCYFF 3: Design and Place Shaping	All proposals will be expected to demonstrate high quality design	**Chapter 3, Site Selection and Consideration of Alternatives**; **Chapter 4, Project Description**; **Chapter 24, Seascape, Landscape and Visual Impact Assessment**
Policy PCYFF 4: Design and Landscaping	All proposals should integrate into their surroundings	
Strategic Policy PS 7: Renewable Energy Technology	the Plan area wherever feasible and viable realises its potential as a leading area for initiatives based on renewable or low carbon energy technologies	**Chapter 1, Introduction**; **Chapter 3, Site Selection and Consideration of Alternatives**; **Chapter 4, Project Description**
Policy ADN 3: Other Renewable Energy and Low Carbon Technologies	Proposals for renewable and low carbon energy technologies, other than wind or solar, which contribute a low carbon future will be permitted, provided that the proposal conforms to certain criteria	**Chapter 7** to **26** present the assessments of impacts from the Project on all receptors.
Policy ARNA 1: Coastal Change Management Area (CChMA)	Proposals for the following types of new non-residential development will be permitted on sites within the CChMA predicted as being at risk from coastal change during the second indicative policy epoch (2026 – 2055), subject to a compliant Flood Consequence Assessment or a Stability Assessment.	**Chapter 17, Water Resources and Flood Risk**. A Flood Risk Assessment has been prepared and is appended to **Chapter 17, Water Resources and Flood Risk**.
Strategic Policy PS 13: Providing Opportunity for a Flourishing Economy	Whilst seeking to protect and enhance the natural and built environment, the Councils will facilitate economic growth in accordance with the spatial strategy of the Plan	**Chapter 3, Site Selection and Consideration of Alternatives**; **Chapter 25, Socioeconomics, Tourism and Recreation**.
Strategic Policy PS 14: The Visitor Economy	Ensuring compatibility with the local economy and communities and ensuring the protection of the	Menter Môn will ensure design of the Project takes appropriate consideration of landscape and seascape sensitivities.

Policy	Description	Where considered within the ES
	natural, built and historic environment	**Chapter 24, Seascape, Landscape and Visual Impact Assessment**
Strategic Policy PS 19: Conserving and Where Appropriate Enhancing the Natural Environment	Manage development so as to conserve and where appropriate enhance the Plan area's distinctive natural environment, countryside and coastline	**Chapter 19, Onshore Ecology**; **Chapter 24, Seascape, Landscape and Visual Impact Assessment**, **Chapter 25, Socioeconomics, Tourism and Recreation**
Policy AMG1: Area of Outstanding Natural Beauty (AONB) Management Plans	Proposals within or affecting the setting and/ or significant views into and out of the AONB must, where appropriate, have regard to the relevant Area of Outstanding Natural Beauty Management Plan.	
Policy AMG 4: Coastal Protection	Developments in Heritage Coasts must have overriding economic and social benefit and not cause unacceptable harm	**Chapter 19, Onshore Ecology**; **Chapter 20 Onshore Archaeology and Cultural Heritage; Chapter 24, Seascape, Landscape and Visual Impact Assessment; Chapter 25, Socioeconomics, Tourism and Recreation**
Policy AMG 5: LOCAL Biodiversity Conservation	Proposals must protect and, where appropriate, enhance biodiversity that has been identified as being important	**Chapter 19, Onshore Ecology; Document MOR/RHDHV/DOC/0067, Information to Support HRA.**
Policy AMG 6: Protecting Sites of Regional or Local Significance	Proposals that are likely to cause direct or indirect significant harm to Local Nature Reserves (LNR), Wildlife Sites (WS) 1 or regionally important geological / geomorphologic sites (RIGS) must have overriding economic and social benefit and not cause unacceptable harm	**Chapter 7, Metocean Conditions and Coastal Processes**; **Chapter 19, Onshore Ecology**
Policy PS 20: Preserving and Where Appropriate Enhancing Heritage Assets	It is important that heritage assets - encompassing archaeology and ancient monuments, listed buildings, conservation areas and historic parks, gardens and landscapes are preserved	**Chapter 20, Onshore Archaeology and Cultural Heritage**; **Chapter 24, Seascape, Landscape and Visual Impact Assessment**

2.3.8.2. Shoreline Management Plan

53. A Shoreline Management Plan (SMP) provides a large-scale assessment of the risks associated with coastal evolution and presents a policy framework to address these risks to people and the developed, historic and natural environment in a sustainable manner. In doing so, an SMP is a high-level document that forms an important part of the Department for Environment, Food and Rural Affairs (Defra) strategy for flood and coastal defence (Defra, 2001).

54. The SMP is a non-statutory policy document for coastal defence management planning. It takes account of other existing planning initiatives and legislative requirements and is intended to

inform wider strategic planning. The shoreline of Wales is divided into a number of Policy Development Zones (PDZ). The coastal area of the Project lies within PDZ17 – Holy Island and West Anglesey (Twyn y Parc to Twyn Cliperau). Further information on the baseline environment presented in the SMP is shown in **Chapter 7**, **Metocean and Coastal Processes**.

2.4. ENVIRONMENTAL LEGISLATION

2.4.1. The EIA Directive

55. Environmental Impact Assessment (EIA) was introduced under the EU EIA Directive 85/337/EEC in 1985 (as amended by Directives 97/11/EC, 2003/35/EC and 2009/31/EC). In 2011, the original EIA Directive and amendments were codified by EIA Directive 2011/92/EU (as amended by Directive 2014/52/EU) (the EIA Directive). The EIA Directive ensures that projects likely to have significant effects on the environment are subject to an EIA prior to their approval or authorisation. The requirement to comply with them is transposed into law by regulations and/or amendments legislation such as the Transport and Works Act 1992 and Transport and Works (Applications and Objections Procedure) (England and Wales) Rules 2006.

56. Key changes which are of note relate to:

- A requirement to provide a description of the likely significant effects of the development on the environment resulting from impacts on climate change, risks to human health and use of natural resources;
- Ensuring EIA quality by requiring that those who undertake the work are competent experts;
- More detailed demonstration of the consideration of reasonable alternatives to the proposed Project; and
- Further consideration of how to avoid, prevent, reduce and / or off-set significant adverse effects where possible and develop monitoring strategies.

2.4.2. The Marine Works (Environmental Impact Assessment) Regulations 2010 (as amended)

57. In respect of works in respect of which a marine licence is required, the EIA Directive has been implemented in to national legislation by The Marine Works (Environmental Impact Assessment) Regulations 2010 as amended by the Marine Works (Environmental Impact Assessment) (Amendment) Regulations 2017. These Regulations implement the EIA Directive, referring to Annex I projects that require mandatory EIA and Annex II projects which may be subject to an EIA, should certain thresholds be exceeded. The Project will require an EIA as an Annex II project that exceeds the relevant thresholds.

58. Schedule 3 of the Marine Works (EIA) Regulations 2010 (as amended) sets out information that must be included in the ES, including:

- A description of the Project;
- A description of the reasonable alternatives studied by the applicant;

- A description of the baseline environment and an outline of the likely evolution thereof without implementation of the Project;
- A description of the factors likely to be significantly affected by the Project;
- A description of the likely significant effects of the project on the environment, including direct effects and any indirect, secondary, cumulative, transboundary, short-term, medium-term and long-term, permanent and temporary, positive and negative effects;
- A description of the forecasting methods or evidence used to identify and assess the significant effects on the environment including details of difficulties (for example, technical deficiencies or lack of knowledge) encountered compiling the required information and the main uncertainties involved;
- A description of the measures envisaged to avoid, prevent, reduce or if possible offset any identified significant adverse effects on the environment and, where appropriate, of any proposed monitoring arrangements (for example, the preparation of a post-project analysis);
- A description of the expected significant adverse effects of the Project on the environment deriving from the vulnerability of the project and the regulated activity to risks of major accidents or disasters which are relevant to the Project and the regulated activity concerned;
- A non-technical summary of the information provided; and
- A reference list detailing the sources used for the descriptions and assessments included in the report.

2.4.3. The Town and Country Planning (Environmental Impact Assessment) (Wales) Regulations 2017

59. Following the amendment to the EIA Directive, the Town and Country Planning (EIA) (Wales) Regulations 2017 came into force. The Town and Country Planning (EIA) (Wales) Regulations 2017 restate the EIA Regulations, with amendments to reflect the changes required by the 2014 Directive and some domestic policy.

60. The primary purpose of the Town and Country Planning (EIA) (Wales) Regulations 2017 is to transpose the changes made to the EIA Directive in respect of land use planning. The Town and Country Planning (EIA) (Wales) Regulations 2017 would therefore be engaged by the grant of deemed planning permission for the onshore works.

2.4.4. Habitats and Birds Directive

61. EC Directive 92/43/EEC on the Conservation of Natural Habitats and of Wild Fauna and Flora (known as the Habitats Directive) is intended to protect biodiversity by requiring Member States to take measures to maintain or restore natural habitats and wild species listed in the Annexes to the Directive at a favourable conservation status. It provides robust protection for those habitats and species of European importance.

62. EC Directive 2009/147/EC on the Conservation of Wild Birds (known as the Birds Directive) provides a framework for the conservation and management of, and human interactions with, wild birds in Europe. It sets broad objectives for a wide range of activities.

63. For territorial waters in England and Wales, where the Project is located, the Habitats Directive and the Birds Directive are implemented under the Conservation of Habitats and Species Regulations 2017 (the Habitats Regulations). The provisions of the Birds Directive are implemented through the Wildlife and Countryside Act 1981 (as amended) and the Habitats Regulations, as well as other legislation related to the uses of land and sea.

64. Under this legislative framework a network of protected areas (the Natura 2000 network) has been established. These protected areas include Special Areas of Conservation (SAC) for habitats and species, and Special Protection Areas (SPA) for wild birds.

65. Ramsar Sites are designated under the Convention on Wetlands of International Importance, ratified by the UK in 1976. Ramsar sites are afforded protection as if they were part of the Natura 2000 network (i.e. SPAs and SACs as set out in the Habitats Regulations). The majority are also classified as SPAs and all terrestrial Ramsar sites in Wales are also notified as Sites of Special Scientific Interest (SSSIs) (see **Chapter 19, Onshore Ecology**).

66. Under the Habitats Regulations the Secretary of State, before granting consent for a plan or project, must consider whether a plan or project has the potential to have a significant effect on a Natura 2000 site either alone or in combination with other plans or projects if it is not directly connected with or necessary to the management of that site. If there is potential for a plan or project to have a likely significant effect on a Natura 2000 site, there is a requirement for the competent authority (in this case NRW (Marine Licence) and Welsh Government (Transport and Works Act Order)) to carry out an Appropriate Assessment. This process is known as Habitats Regulations Assessment (HRA). However, it is the developer's responsibility to provide sufficient information to the competent authority to enable them to assess whether there are likely to be any significant effects and to enable them to carry out the Appropriate Assessment. A standalone Habitats Regulation Assessment (HRA) report is submitted alongside this ES as part of the application (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**). This report will provide all the necessary information for the competent authority to carry out the Appropriate Assessment as required before determining applications for the Transport and Works Act Order and Marine Licence.

67. European Protected Species (EPS) are animals and plants listed in Annex IV of the Habitats Directive for whom Great Britain is their natural range. They are listed in Schedules 2 and 5 of the Habitats Regulations. The Habitats Regulations make it an offence to kill, injure, capture or disturb marine EPS and to pick, collect, cut, uproot or destroy a wild plant which is an EPS. In relation to the Project, **Chapter 12, Marine Mammals** will identify whether an EPS licence is expected to be required for disturbance of cetaceans in the study area and **Chapter 19, Onshore Ecology** will discuss the potential requirement of an EPS licence for terrestrial species. The need for an EPS licence will be determined in consultation with NRW.

2.4.5. Water Framework Directive

68. The EU Water Framework Directive 2000/60/EC is transposed into law in England and Wales by the Water Environment (Water Framework Directive) (England and Wales) Regulations 2017. The Regulations mean that the requirements of the Water Framework Directive (WFD) need to be considered at all stages of the planning and development process, which may impact on water bodies. The WFD requires that Environmental Objectives are set for all surface waters and ground waters in each EU Member State.

69. The WFD set a target of aiming to achieve at least ‘good status’ in all water bodies by 2015. However, provided that certain conditions are satisfied, in some cases the achievement of good status may be delayed until 2021 or 2027.

70. Specific mitigation measures are set for water bodies to achieve the Environmental Objectives of the WFD. These are listed within the Programme of Measures for each River Basin Management Plan (RBMP). RBMPs have been drawn up for each River Basin District across England and Wales and propose measures to protect and improve the water environment. These measures have been developed in consultation with organisations and individuals and are intended to mitigate impacts that have been or are being caused by human activity, such as flood and coastal defence works, with the aim of restoring and enhancing the quality of the existing environment. The Project is located within the Western Wales River Basin District. **Chapter 17, Water Resources and Flood Risk** provides further information on the WFD as well as providing an assessment of the project in relation to the WFD objectives.

2.4.6. Marine Strategy Framework Directive

71. The Marine Strategy Framework Directive 2008/56/EC (MSFD) establishes a common approach and objectives for the prevention, protection and conservation of the marine environment. The MSFD outlines a transparent legislative framework for an ecosystem-based approach to the management of human activities, which supports the sustainable use of marine goods and services. It requires countries to develop strategies and set targets to achieve ‘good environmental status’ by 2020, which include measures that protect the marine ecosystem and ensure economic activities linked to the marine environment are sustainable.

72. The Convention for the Protection of the Marine Environment of the North-East Atlantic (the OSPAR Convention) plays a key role as one of the co-ordinating mechanisms to help Member States meet the obligations of the MSFD. The OSPAR Convention has been signed and ratified by sixteen Contracting Parties, including the United Kingdom, and contains a series of Annexes covering prevention and elimination of pollution, assessment of the quality of the marine environment and protection and conservation of the ecosystems and biological diversity of the maritime area. **Chapter 8, Marine Water and Sediment Quality** provides further information on the MSFD.

2.4.7. Wildlife and Countryside Act 1981

73. The Wildlife and Countryside Act 1981 is the principal legislative mechanism for the protection of wildlife in Great Britain and is the means by which the Convention on the Conservation of European Wildlife and Natural Habitats (the 'Bern Convention') and the Habitats Directive are implemented. For territorial waters in England and Wales, where the Project is located, the Habitats Directive and the Birds Directive are implemented under the Conservation of Habitats

and Species Regulations 2017 (the Habitats Regulations). The provisions of the Birds Directive are implemented through the Wildlife and Countryside Act 1981 (as amended) and the Habitats Regulations, as well as other legislation related to the uses of land and sea.

74. The Wildlife and Countryside Act 1981 is divided into four parts. Those relevant to the Project are as follows:

- Part I: relates to the protection of wildlife; and
- Part II: deals with the protection of Sites of Special Scientific Interest (SSSIs) and other designated sites.

75. The Wildlife and Countryside Act 1981 provides for the notification and confirmation of Sites of Special Scientific Interest (SSSIs) through the local planning authority. SSSIs are sites identified for their flora, fauna, geological or physiographical features by Natural England in England and NRW in Wales. The Act also contains measures for the protection and management of SSSIs.

76. Any potential impacts on terrestrial flora and fauna are discussed further in **Chapter 19, Onshore Ecology** and those on marine flora and fauna in **Chapter 9, Benthic and Intertidal Ecology**, **Chapter 12, Marine Mammals**, and **Chapter 10, Fish and Shellfish**.

2.4.8. Countryside and Rights of Way Act 2000

77. The Countryside and Rights of Way Act 2000 (CRoW) provides for public access on foot to certain types of land, increases measures for the management and protection of SSSIs, strengthens wildlife enforcement legislation and provides for better management of Areas of Outstanding Natural Beauty (AONB).

78. The CRoW requires local authorities to produce management plans for each AONB, and enables the creation of Conservation Boards in order to assume responsibility for AONBs, particularly where the land designated crosses several local authority jurisdictions. The CRoW also requires all relevant authorities to have regard to the purpose of conserving and enhancing the natural beauty of AONBs when performing their functions. Any potential impacts as a result of the Project on the natural beauty of AONBs are discussed further in **Chapter 24, Seascape, Landscape and Visual Impact Assessment.**

2.4.9. Natural Environment and Rural Communities Act 2006

79. The UK Biodiversity Action Plan (UK BAP), published in 1994, was the UK Government's response to signing the Convention on Biological Diversity (CBD) at the 1992 Rio Earth Summit. The new UK post-2010 Biodiversity Framework replaces the previous UK level Biodiversity Action Plan.

80. The Natural Environment and Rural Communities (NERC) Act came into force in 2006. Section 42 (s42) of the NERC Act 2006 requires the Secretary of State to publish a list of habitats and species which are of principal importance for the conservation of biodiversity in Wales. The NERC Act is repealed by the Environment (Wales) Act 2016 (**Section 2.4.10**).

81. Fifty-five habitats and 557 species of principal importance are included on the s42 lists. These are all the habitats or species in Wales that were identified as requiring action in the UK BAP

and continue to be regarded as conservation priorities in the subsequent UK Post-2010 Biodiversity Framework. They include terrestrial, freshwater and marine habitats and species.

82. Any potential impacts on habitats and species of principal importance as a consequence of the Project are discussed further in **Chapter 19, Onshore Ecology** and on marine flora and fauna in **Chapter 9, Benthic and Intertidal Ecology**, **Chapter 12, Marine Mammals** and **Chapter 10, Fish and Shellfish**.

2.4.10. The Environment (Wales) Act 2016

83. The Environment (Wales) Act 2016, which replaces the Section 40 and Section 42 duty in the NERC Act 2006, puts in place a modern statutory process to plan and manage natural resources in Wales. The Environment (Wales) Act 2016 enables Welsh resources to be managed in a more proactive, sustainable and joined up way and provides Welsh Ministers with powers to put in place statutory emission reduction targets. The Environment (Wales) Act 2016 also places a duty on Welsh Ministers to prepare and implement a statutory National Natural Resource Policy (NNRP) which should be used to set out priorities in relation the natural resource management.

84. Section 6 under Part 1 of the Environment (Wales) Act 2016 introduces a duty on local authorities in Wales to seek to enhance biodiversity and resilience of ecosystems when carrying out functions. Section 7 under the Environment (Wales) Act 2016 replaces the Section 42 duty in the NERC Act 2006. Welsh Ministers are required to publish and review lists of species and habitats in Wales, which are of key significance to sustain and improve biodiversity in relation to Wales. All public authorities, in complying with the Section 6 duty, must have regard to the Section 7 list of habitats and species. Currently, the interim list is exactly the same as the previous list under Section 42 of the NERC Act 2006; however, it is under review in consultation with NRW.

2.5. PROJECT DESIGN ENVELOPE (ROCHDALE ENVELOPE)

85. An essential element of any EIA is defining the project description against which impacts will be assessed. Due to the nature of the Project and the evolving nature of the tidal energy sector, full details of the offshore element of the proposed development cannot be fixed at the time of the application. For example, the tidal devices to be installed are dependent on an array selection process, and the detailed installation method is dependent on the tidal device type and the availability/procurement of vessels at the time of installation. Therefore, the project description and methods upon which this application for consent is based, fall within a range of defined criteria – an envelope of potential development, which describes the maximum potential extent and nature of the development. This approach allows a degree of flexibility in determining the final specific project details, while still meeting the requirements of the EIA process.

86. This approach is termed the 'Rochdale Envelope' approach in the context of applications for Development Consent Orders, with associated case law established in R.v Rochdale Metropolitan Borough Council ex p. Milne (2000). This approach is endorsed in the revised draft Overarching National Policy Statement (NPS) for Energy (EN-1), the revised draft NPS for Renewable Energy Infrastructure (EN-3), and guidance provided in the Infrastructure Planning Commission (IPC, now the Planning Inspectorate) Advice Note Nine.

87. The ‘Rochdale Envelope’ approach defines a series of realistic maximum extents and magnitudes for the description of a development (an envelope), of which the impacts are assessed. In this way a realistic ‘worst case scenario’ is assessed. Post consent, a detailed design of the scheme can vary within that envelope and the parameters assessed, without rendering the EIA inadequate. By adopting this approach, the ES can conclude that the environmental impact of the Project will be no greater than that set out in the ES and may be less.

88. **Chapter 4, Project Description** sets out the parameters of the Project. Where site specific details have not yet been finalised, then a minimum and maximum number have been presented. Where that specific parameter is relevant to the assessment, the worst case for that element has been identified by the relevant specialist and used as the basis for that assessment. Each technical chapter (**Chapters 7** to **27**) provides an outline of the relevant worst case for that receptor.

89. The design will be refined in response to technology availability, consultation, environmental sensitivities, choice of contractors and economic considerations. Best efforts have been made to incorporate all permutations of infrastructure that may be associated with the Project.

90. Prior to each array deployment, it is expected that there will be consent conditions requiring documentation to be submitted to the licensing authorities (Welsh Government and Natural Resources Wales, NRW) outlining the parameters of the tidal devices to be installed as well as providing details of the construction methodology, O&M strategy, and the array removal (decommissioning) methodology. This will allow review of each array’s characteristics against the consented Project Design Envelope (PDE).

91. A statement confirming that each array deployment fits within the PDE will be submitted by Menter Môn to the Welsh Government and NRW for approval. If an array deployment is outwith the PDE, additional consenting or amendment to the Project consent will be required before deployment.

92. In addition to the development site flexibility, options are included within the onshore site to allow the consent to be future proofed in relation to land availability and to allow flexibility to avoid constraints if identified during pre-construction site investigations. In particular, the Onshore Development Area (ODA) encompasses sufficient area to allow the micro-siting and potential relocation of onshore infrastructure if required.

TABLE OF CONTENTS

TABLE OF TABLES

TABLE OF FIGURES (VOLUME II)

GLOSSARY OF ABBREVIATIONS

DP	Dynamic Positioning
ECC	Export Cable Corridor
EIA	Environmental Impact Assessment
ES	Environmental Statement
FEED	Front End Engineering and Design
GBS	Gravity Based Structures
HDD	Horizontal Directional Drilling
km	Kilometres
kV	Kilo volts
LAT	Lowest Astronomical Tide
MDZ	Morlais Demonstration Zone
MW	Megawatts
NRW	Natural Resources Wales
O&M	Operation and Maintenance
PDE	Project Design Envelope
RLB	Red Line Boundary
rpm	Rotations per Minute
TEC	Tidal Energy Converters
TWAO	Transport and Work Act Order
UKC	Under Keel Clearance

GLOSSARY OF TERMINOLOGY

Axial Flow	Horizontal axis rotors.
Category 1 tidal device	Seabed Mounted Sub-Surface Tidal Devices.
Category 2 tidal device	Buoyant Mid-water Column Tidal Devices.
Category 3 tidal devices	Floating and / or Surface Emergent Tidal Devices.
Cross Flow	Vertical axis rotors.

3. SITE SELECTION AND CONSIDERATION OF ALTERNATIVES

3.1. INTRODUCTION

1. Menter Môn Morlais Limited (hereafter referred to as Menter Môn) proposes the development of 240 MW of tidal generating capacity within the Morlais Demonstration Zone (MDZ). Development of the Morlais Project (the Project) will support the objectives of the Anglesey and Gwynedd Joint Local Development Plan (JLDP), aimed at promoting the development of renewable energy technology. The Project will prioritise the maximisation of opportunities for local communities directly via employment and indirectly via the establishment of a local supply chain. Through development of the Project, Menter Môn seeks to establish Anglesey as a marine energy hub.

2. The development of the Project will provide a consented tidal technology demonstration zone, specifically designed for the installation and demonstration of arrays of tidal energy devices (tidal devices). The Project will provide communal infrastructure to its tenants, tidal technology and project developers, enabling a shared route to grid connection using the Project's export cables, Landfall Substation, onshore cable route and Grid Connection Substation.

3. Details of the infrastructure that forms the Project and is considered in this ES, are provided in **Chapter 1, Introduction** and in **Chapter 4, Project Description**.

4. This chapter summarises the site selection process for the Project, including the background to selection of the MDZ, tidal devices, the offshore cable route, cable landfall location, landfall substation location, the onshore cable route, Switchgear Building location and the Grid Connection Substation location.

5. This chapter presents an overview of the decision-making process for each element of the project outlined above and is separated in to these discrete sections. However, note that these aspects are often interrelated and were undertaken in a parallel and iterative basis, rather than sequential approach. For example, selection of the landfall substation location was based on an overview of onshore constraints but also took into consideration the outcomes of the assessment of offshore export cable corridor and cable landfall point locations.

6. The broad process of project selection is outlined in **Plate 3-1**. The processes are iterative, ensuring that the ES chapters inform the decision-making process.

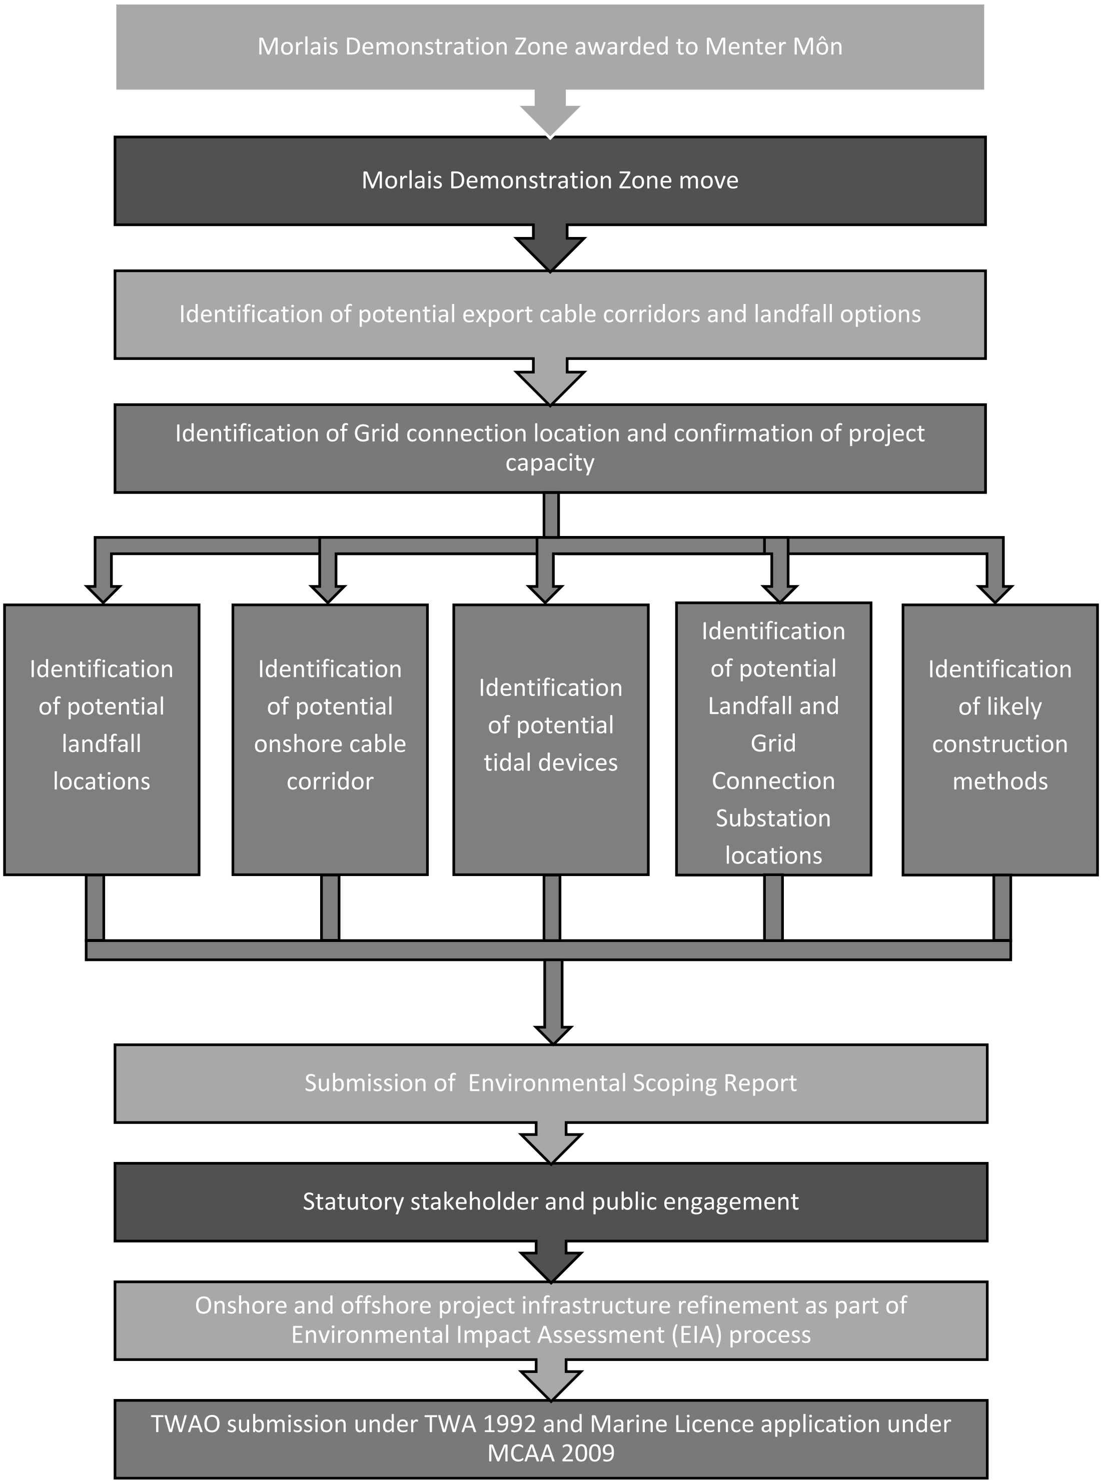

Plate 3-1 Site selection process for the Project

3.2. LEGISLATION AND GUIDANCE

3.2.1. Environmental Impact Assessment Regulations

7. The consideration of alternatives and major design decisions made during the development of a project has been part of Environmental Impact Assessment (EIA) legislation since the adoption of the original European Union (EU) EIA Directive 85/337/EEC in 1985 (as amended by Directives 97/11/EC, 2003/35/EC and 2009/31/EC) and is also included within amended Directive 2014/52/EU.

8. The Marine Works (Environmental Impact Assessment) (Amendment) Regulations 2017 and The Town and Country Planning (Environmental Impact Assessment) (Wales) Regulations 2016 provide the following description of what should be included within the Environmental Statement (ES); "*A description of the reasonable alternatives (for example in terms of project design, technology, location, size and scale) studied by the developer, which are relevant to the proposed project and its specific characteristics, and an indication of the main reasons for selecting the chosen option, including a comparison of the environmental effects*."

9. The Transport and Works (Applications and Objections Procedure) (England and Wales) Rules 2006 amend the wording slightly but do not significantly change the position. The legislation requires an ES to include "*an outline of the main alternatives to the proposed works studied by the applicant and an indication of the main reason for his choice, taking into account the environmental effects*".

3.3. WHY ANGLESEY?

10. The United Kingdom (UK) has the largest wave and tidal resource in Europe. The Marine Renewable Energy Strategic Framework (MRESF), found a potential for 1.5 to 6.5 GW of installed capacity in Welsh waters (Regeneris, 2013). **Chapter 1, Introduction** provides an overview of the tidal resource of the UK.

11. The MDZ is one of several development areas around the UK which have been identified by The Crown Estate (TCE) in a bid to encourage and accelerate technology development. Each area was identified because it offered appropriate wave and tidal energy potential, as well as access to necessary infrastructure, including ports and electricity grid.

12. The MDZ is an area of 35 km^2 located west of Holy Island, itself off the west coast of the Isle of Anglesey. The MDZ is approximately 7 km from north to south and 5 km from east to west, with the eastern boundary less than 1 km from shore at its closest point. The strength of tidal flow varies across the site with higher levels experienced to the north of the MDZ and in those parts of the MDZ closest to the coast of Holy Island.

13. The MDZ has a mean and maximum water depth of 38.4 m and 80 m, respectively. A mean spring peak velocity (V_{msp}) was estimated by TCE to be 1.7 m/s. Other sources estimate peak spring tide currents (V_{pk}) in excess of 2.5 m/s across large areas of the region (Piano *et al*., 2015), with the potential to reach accelerated flows of up to 3.1 m/s V_{msp} in some parts of the MDZ. The highest velocities within the MDZ are recorded just off Holy Island (4.0 m/s) (see **Chapter 7, Metocean Conditions and Coastal Processes**).

14. A feasibility study commissioned by Isle of Anglesey County Council (IoACC) (Feasibility Study for a Marine Energy Programme – a Marine Energy Sector Development Programme 2013) described the marine energy sector as "*a major opportunity for transformational economic growth*" for North Wales and recognised the importance of "*supporting and encouraging local marine skills capability and supply chain capacity…to create positive regional impacts and benefits*."

15. In pursuit of this commitment, IoACC established The Anglesey Energy Island Programme, a collective effort between several stakeholders within the public, private and third sectors working in partnership, putting Anglesey at the forefront of low carbon energy research and development, production and servicing, and bringing with it potentially huge economic rewards.

16. Energy Island's vision is to create a once-in-a-lifetime opportunity for jobs, economic growth and prosperity through capitalising on a number of transformational projects on Anglesey. The Energy Island Programme collaborates with a number of key stakeholders to:

- Attract and de-risk major strategic investment;
- Influence potential developers;
- Support development of competitive people and communities;
- Support development of competitive businesses;
- Support development of competitive infrastructure;
- Realise the benefits major projects can bring and mitigate adverse impacts; and
- Maximise long-term legacy benefits.

17. The developer, Menter Môn, is a not for profit social enterprise company providing solutions to the challenges facing North Wales. Menter Môn has a strong local presence on Anglesey and a passion for developing renewable energy on the Island, and to increase and diversify employment and economic development opportunities.

3.4. PROJECT ALTERNATIVES

18. A number of alternatives have been considered as part of the decision-making process. The early strategic project consideration of alternatives which fed directly into the site selection process are detailed in **Table 3-1**.

Table 3-1 Outline of Alternative Considerations and Final Selection

Topic	Consideration of alternatives	Final selection for the Project
Project size	The initial project concept had a capacity of less than 100 MW. However, the availability of tidal resource (velocities between 2.2 to 2.8 m/s across most of the site, with peak of 4.0 m/s) across the MDZ, updates in technology and increased interest from tidal device developers for deployment in the MDZ led to an increase in the proposed installed	The final capacity for the Project to be applied for consent is 240 MW.

Topic	Consideration of alternatives	Final selection for the Project
	capacity, initially to 180 MW and now to 240 MW.	
MDZ location	A review of the baseline metocean conditions highlighted that the tidal range across the MDZ is variable and is greater to the north and east of the MDZ. Shortly after appointment of Menter Môn as managers of the MDZ by TCE, Menter Môn requested to TCE that the MDZ be moved north, so as to include more areas of greater tidal resource.	Menter Môn consulted with marine stakeholders on the request to move the MDZ north. TCE subsequently agreed to the request.
Tidal devices	A wide variety of devices was initially proposed as providing exemplars to define the design envelope for the Project. The list of devices considered was revised to allow for removal of devices for which insufficient information was available to allow definition of design parameters.	12 shortlisted devices (those with sufficient information from developers), were used to define this aspect of the project design envelope. The tidal devices have been placed into categories depending on their scale, and their position in the water column (see **Section 3.8.1**).
Export cable corridor	An area from Holyhead to Trearddur Bay was analysed to identify suitable landfall points and substation locations. An initial review of the baseline physical environment by Menter Môn identified that cable burial would not be possible throughout the majority of the potential export cable corridor.	A variety of alternative cable laying options was reviewed due to the existing geomorphological conditions. This will be refined post submission; however, a worst-case scenario forms the basis of the Morlais ES (**Chapter 4, Project Description**).
Landfall area	A long list of 15 landfall areas with a variety of construction techniques was reviewed for suitability to the variable Holy Island coastline.	Landfall sites were shortlisted on the basis of a number of considerations including, nature conservation designations, existing infrastructure, feasibility of construction, seabed suitability for cable laying and length of export cables.
	A short list of four landfall locations within the Abrahams Bosom area of west Holy Island were selected for further investigation. Due to the cliff and foreshore geology, a range of construction techniques were reviewed.	Key receptors included noise and visual disturbance to residential properties adjacent to the landfall site, and minimising disturbance to both ecological designations, foreshore and cliff line within Area of Outstanding Natural Beauty (AONB) and Heritage Coast. Options for split pipe cable laying within trenches, and Horizontal Directional Drilling (HDD) were identified.
Landfall Substation	A long list of 13 landfall substation locations was considered. Landfall substation locations were shortlisted based on a number of considerations, including nature	A final site was chosen based on further consideration of nature conservation designations and landowner discussions. Further consideration of potential visual impacts results in the position of the Landfall Substation within

Topic	Consideration of alternatives	Final selection for the Project
	conservation designations, existing infrastructure and potential visual impacts. Key considerations were the feasibility of landfall construction using the preferred trenching and HDD methods, and the distance of the Landfall Substation from the landfall. A short list of four options, within Abrahams Bosom were selected for further investigation.	a recessive location in the landscape and uses the landform to help integrate the substation into the landscape.
Grid connection point	The closest four options to the project site were considered. Those were refined to the three closest, with two on Holy Island to minimise disturbance during cable trenching works; one at the Parc Cybi employment site and one at the existing Anglesey Aluminium and Orthios site.	The preferred location for connection to the existing electricity network, for the full 240 MW installed capacity, is the Grid Connection Substation at Orthios. This is due to the proximity to an existing substation for minimising visual impacts, technical considerations and the use of land within a brownfield site, in order to minimise disturbance to onshore ecology and local residents.
Switchgear station	The location of a substation at Parc Cybi was considered as one of 4 grid connection point options (above).	The 33 kV connection point at ‘Parc Cybi’ is selected as a suitable location for a switchgear building. This offers connection of early phases of the Project to the local electricity network, whilst the 132 kV grid connection point ‘Orthios’ is connected to the national transmission network.
Onshore cable route	Given the rural nature of the project, the location of the AONB, public perception and consultation with IoACC, it was decided that overhead cables would not be appropriate. Only options for traditional trenching methods of cable installation between the Landfall Substation and Grid Connection Substation were reviewed.	The final onshore cable route is selected to minimised disturbance to the natural environment on Holy Island. Therefore, the onshore cable route will be of up to 8.1 km total route length, dependent on final detailed route design, with the cables trenched into the local road network so much as is practicable given constraints in road width and services already within the road. The final cable corridor and proposed route is presented in **Chapter 4, Project Description**.

3.5. SITE SELECTION PROCESS

19. The siting, design and refinement of the Project has followed a site selection process, taking account of environmental, physical, technical, commercial and social considerations and opportunities, as well as engineering requirements. The aim has been to identifying sites that will be environmentally acceptable whilst also being technically and financially achievable. A multi-disciplinary design team was formed to undertake the site selection process, which included engineering and EIA consultants.

20. Menter Môn has undertaken extensive pre-application engagement with stakeholders, communities and landowners in order to refine the final project design, and to communicate decisions made to achieve those refinements.

21. Consultation and refinements to project layout and configurations has been undertaken since Menter Môn Cyf had been awarded the right to manage what was then known as the West Anglesey Demonstration Zone (WADZ) in July 2014. Further details of consultation are outlined in **Chapter 6, Consultation** and described in detail in the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**). In summary, mechanisms used to refine the project have included:

- Drop in Exhibitions held at locations within and adjacent to the Onshore Development Area;
  - First Public Information Day (PID) held on the 19th March 2019; and
  - Second PID held over three sessions on 11th, 12th and 17th June 2019.
  - Feedback from each group at the PIDs is incorporated into the Consultation Report (Document MOR/RHDHV/DOC/0066, Consultation Report) and used in the relevant receptor impact assessments, as well as being outlined in the ES.
- Community engagement events, focussing on town and community councillors;
- Engagement with relevant local authorities, landowners, community councils and other local stakeholders, in order to raise awareness of the Project, to outline the consenting process and to highlight opportunities to input to proposals.
  - Consultation has been undertaken directly with landowners and interested parties including tenants, occupiers and other parties with land rights. Engagement with individual land owners within or adjacent to the proposed development was managed directly by Menter Môn, with support from their appointed Land Agent. Letters were sent to all potentially affected parties offering to meet to discuss the project proposals;
- Menter Môn's land agents have contacted the affected landowners. A number of onshore cable route change suggestions have been put forward by those affected by the red line boundary (RLB). Menter Môn have been able to incorporate a number of those suggestions into the final design of the Project. Newsletters distributed throughout the Scoping Area, as described in the Consultation Report. These newsletters were distributed prior to each PID event; in March and June;
- Leafleting relevant communities to 'capture' hard to reach groups;
- Provision of a dedicated project website; and
- Regular and targeted discussion with regulators and other stakeholder bodies through various means including Technical Working Group meetings, where the siting of project infrastructure was discussed in detail. More information is provided in **Chapter 6, Consultation**.

22. In addition to the consultation activities presented below, Menter Môn met with the Planning Inspectorate and IoACC's Planning Officer on a regular basis throughout the development of

the Project, to provide updates and to seek advice on subjects including the site selection process, approach to the EIA and drafting the application documents.

3.6. DEFINING THE SCOPING AREA

23. The initial offshore scoping area followed the boundaries of the MDZ. The onshore scoping area encompassed the location of all landfall, substation and cable route options being considered, including appropriate buffers around each location (minimum of 500 m around landfall and onshore substation locations and 300 m around onshore cable routes). The buffers applied include all areas required for temporary construction.

24. The scoping area around the potential onshore infrastructure locations was developed to identify sensitive receptors likely to be present a distance of the development where they are likely to receive impacts. For most receptors, physical disturbance is likely to be a key consideration. Disturbance from noise is also likely to be a key consideration, particularly to ecological and human receptors.

25. Onshore construction works will be restricted to the footprint of the substations and onshore cable routes, plus an appropriate buffer, ensuring that physical disturbance is localised.

26. Noise receptors within 500 m of the substation are likely to be most impacted, although potential for impacts to occur beyond 500 m will also be considered within the EIA.

27. Potential for visual impact over a far greater area exists and zones of theoretical visibility (ZTV) were used to define the potential scale of impacts.

28. Terrestrial ecological receptors are anticipated to be less sensitive to cable installation, and a 300 m buffer was used for identifying sensitive receptors for this reason. The potential to impact on receptors further than 300 m away will also be considered in greater detail during the EIA.

29. Following the definition of the offshore project area, site selection for all other infrastructure was assessed in a strategic manner such that the areas identified would be sufficiently assessed and to allow for site refinement.

30. A number of external studies were commissioned by Menter Môn, including the following;

- Cable Routing Report (ITP Energised Ltd. (ITPE), 2018a);
- Device Developer Consultation Report (ITPE, 2018b);
- Generation Connection Options (Sustainable Electrical Supply Ltd. (SESupply) 2016;
- Morlais Above Ground Landfall construction options (ITPE, 2017);
- Preliminary Design Options Report (ITPE, 2018c); and
- Substation Location Feasibility Study (ITPE, 2016d).

31. The outputs of these technical studies are provided in sections (**Section 3.9.1** to **Section 3.12**).

32. Utilising the details within these technical studies, a Front-End Engineering Design (FEED) study was undertaken by ITP Energised (ITPE) on behalf of Menter Môn in 2017, to provide the

proposed design of the project necessary to inform the EIA project description for consent **(Appendix 4.1, Volume III)**. Further to a revision of proposed installed project capacity to 240 MW, an addendum to the study was undertaken for the MDZ elements **(Appendix 4.2, Volume III)**, also by ITPE. In parallel, Black and Veatch Ltd. (B&V) have been responsible for further design of, and updates to, the onshore infrastructure within the ODA.

3.7. IDENTIFICATION OF THE MORLAIS DEMONSTRATION ZONE

33. TCE's site selection process began in 2013 with the identification of 11 wave and tidal energy demonstration zones. The MDZ was identified as being a suitable location for the installation of tidal devices in the short to medium term, having a good tidal current resource, over a relatively uniform water depth to seabed and a relatively low wave regime.

34. TCE undertook extensive consultation with marine user groups during the process of demonstration zone identification and a competitive leasing process was then undertaken to identify suitable locally based organisations to manage and sub-let the sea bed within each of the zones.

35. In July 2014 TCE announced that Menter Môn had been awarded the right to manage what was then known as the West Anglesey Demonstration Zone (WADZ), and to sub-let use of the seabed to other bodies who could take forward the development of tidal technology in the UK. The WADZ is described in this ES as the Morlais Demonstration Zone (MDZ).

36. After an assessment of the distribution of tidal stream resource within the MDZ, in 2015, Menter Môn applied to TCE for the movement of the MDZ further to the north, to better capture the main areas of significant tidal stream flow to the west of Anglesey. Menter Môn consulted stakeholders on the proposed move and TCE approved the change in 2016.

3.8. IDENTIFICATION OF TIDAL ENERGY DEVICES

37. In order to understand the potential consent requirements for the project and the design envelope needed, it was necessary to identify the potential tidal devices which could be deployed within the MDZ.

38. A detailed review of the device types and technologies with realistic potential to be deployed in the MDZ was undertaken. A key objective of this review was to allow the Project Design Envelope to be defined to encompass a realistic range of tidal devices and technologies.

39. A number of tidal technology developers were contacted, either those expressing an interest in the project, or those whose technologies were considered to be potentially available at the time of the Project's construction.

40. The developers contacted were

- Andritz Hydro Hammerfest;
- Aquantis;
- Atlantis Resources Corporation;

- Instream Energy Systems;
- Magallanes;
- Nova;
- OpenHydro (now no longer trading);
- QED Naval;
- Renewable Devices;
- Repetitive Energy;
- Sabella;
- Orbital Marine Power;
- TidalStream (Schottel Hydro);
- Tocardo;
- Verdant Isles;
- Hydroquest; and
- Big Moon.

41. Consultation was undertaken to obtain information on the technical data of the devices, infrastructure requirements, and deployment, operation and maintenance requirements. Other objectives included obtaining an understanding of the approximate deployment timescales and phasing options and the power output characteristics to inform grid connection studies. A number of parameters were discussed and are summarised in **Table 3-2**.

Table 3-2 Design Considerations of Potential Tidal Devices to Inform PDE Development

Component	Design Considerations
Timing	Planned installation dates and phasing
	Length of deployments
Subzone layout	Number of devices
	Device spacing and potential layout of devices and infrastructure within the sub-zone
	Aggregation strategy
	Connection to transmission infrastructure
Device design	Device size
	Device configuration (axial/transverse/other)
	Surface piercing/floating/sub surface
	Foundation/mooring type and design (GBS/piled)
	Footprint of deployment
	Blade number, dimensions and rotation speed
	Electrical output – rated capacity and voltage; and import power requirements
	Control strategy including location of converters
	Communications and electrical isolation methodology
	Structure and materials

Component	Design Considerations
	Fluids on board and potential discharges
Installation approach	Duration and seasonality of offshore installation activity
	Installation equipment and vessels to be used
	Methodology
	Port requirements
	Hard standings and road access
Operational and maintenance considerations	Personnel and vessels required
	Frequency of scheduled maintenance interventions
	Frequency and type of scheduled surveys
	Unscheduled maintenance
	Back-up electricity supply requirement
	Port requirements
Decommissioning	Approach to decommissioning

3.8.1. Device Selection Methodology

42. A range of devices were identified during the initial consultation, from axial flow and cross flow turbines to turbine neutral platforms. The largest devices are 2 MW, and the smallest are between 50 kW and 100 kW. Rotor sizes vary between 5 m and 27 m in diameter. Some developers have a design employing more than one rotor on their structure. The average speed of TEC rotation considered within the Project Design Envelop (PDE) is between 7.5 and 26.7 rotations per minute (rpm).

43. Some developers would deploy surface emergent technology at the site. Whilst some require deep water (greater than 40 m), others would prefer shallower areas for deployment. Three foundation/mooring types are required: gravity base systems, drilled monopile and driller multi-pin pile.

44. The footprint of deployment varies significantly between developers, with single, bottom mounted turbines requiring a smaller seabed area per device (<300 m^2) in comparison to floating devices with a 'Swept Area' (area that could be subject to mooring line drag) up to 1,000 m^2 per device, in some cases.

45. Based on the information gained, significant consideration has been given to those device types which would be least likely to have an adverse effect on the particular site sensitivities (i.e. visual impact, collision risk to marine mammals and birds). There is a wide range of novel device types available; however, in order to achieve a meaningful impact assessment, some limitations were imposed. The typical, as well as the 'worst case', parameters for all of the devices are summarised in ITPE's Project Design Envelope Definition report to Menter Môn (ITPE, 2018c).

46. A number of device categories were excluded from further consideration due to technology status, or wider potential consenting risks. Those categories included;

- Surface emergent, seabed mounted tower;
- Large seabed mounted cross flow, horizontally orientated;

- Ducted cross-flow; and
- Other 'novel' designs.

47. The devices to be included within the Project Design Envelope have been categorised into three categories: seabed mounted devices, mid-water column devices and surface emergent / floating devices. Devices in each category can support single or multiple tidal energy converters (TEC), with those TECs potentially being of a horizontal axis, or vertical axis form. The categories are described in more detail in **Chapter 4, Project Description**, however, the following key elements are common across the device types:

- Foundation or anchors on the seabed;
- A supporting substructure;
- A Tidal Energy Converter (TEC);
- Seabed preparation; and
- Cable connections.

48. Further detail on the device types is included in **Chapter 4, Project Description**. The device types assessed in this EIA, are deemed to represent the most realistic worst case device parameters for deployment at Morlais. Any device types which are not encompassed by the Project Design Envelope, but which are proposed for deployment at Morlais following consent, will require additional licencing from the Welsh Government and NRW.

3.8.2. Zoning

49. The MDZ has been provisionally divided into eight indicative subzones. Each subzone should have the potential to be developed with up to 30 MW of installed capacity in terms of resource availability and physical space for deployment. However, the eventual installed capacity of each subzone will vary based on the nature of environmental constraints, potential requirements for phasing of deployment and the needs of specific tidal device developers. The Project Design Envelope is designed to represent a realistic worst-case scenario, incorporating the technologies most likely to be deployed, at a capacity and in a location that is realistic.

50. Indicative layouts, each with a different combination of device arrays (sub-categories) in different locations were examined, based on a number of constraints, such as tidal resource, water depth navigation and potential seascape impacts. Further information on the devices included in the PDE and indicative layouts are presented in **Chapter 4, Project Description**.

3.9. IDENTIFICATION OF EXPORT CABLE CORRIDOR AND LANDFALL AREA

3.9.1. Route Feasibility and Screening

51. An area of coast from Holyhead to Trearddur Bay was analysed to identify suitable cable landfall points export cable corridors. Areas outside of this region were not considered due to the length of the subsea cables that would be required from the offshore development site.

52. Offshore constraints identified in the export cable route feasibility exercise were as follows:

- Distance from the development site offshore to the identified landfall points;
- Bathymetry;
- Ground conditions and water depth in the area at landfall;
- Shipping and navigation routes;
- Existing infrastructure;
- Military Practice and Exercise Areas (PEXAs);
- Aggregate dredging grounds;
- Nature conservation designations;
- Commercial fishing; and
- Sensitive seabed features.

53. The majority of the coastline in this area is covered by high level designations, including:

- Glannau Ynys Gybi / Holy Island Coast Special Protection Area (SPA), Special Area of Conservation (SAC) and Site of Special Scientific Interest (SSSI);
- North Anglesey Marine / Gogledd Môn Forol SAC;
- Anglesey Terns / Morwenoliaid Ynys Môn SPA;
- Ynys Mon / Anglesey Area of Outstanding Natural Beauty (AONB);
- South Stack Cliffs Royal Society for the Protection of Birds (RSPB) Reserve; and
- Holyhead Mountain Heritage Coast.

54. In parallel with the landfall and export cable corridor assessment, Menter Môn identified location options for provisional landfall substations (described further in **Section 3.10**). **Figure 3-2 (Volume II)** illustrates the nearby nature conservation designations and initial long list of landfall and landfall substation locations.

55. Due to the heterogenous and complex nature of the coastal area evidenced by the large number of designations, a comprehensive site selection and feasibility assessment was undertaken to better understand the ecological and geological risks associated with each landfall and offshore export cable corridor option. Where possible, sensitive designation have been avoided. From this, offshore export cable corridors were outlined (see **Figure 3-1, Volume II**).

3.9.2. Export Cable Specifications

56. Three main options (and variations on these) for connecting the MDZ to the landfall location were reviewed as part of the route feasibility process;

- **Option 1:** Individual cable to shore for each subzone
    - Option 1a: Multiple cables for each subzone
    - Option 1b: Multi-core cable used so sub-zones are combined in pairs, with one 6 core cable per 2 sub-zones

- **Option 2:** Single 132kV cable to shore for all subzones with offshore substation
    - Option 2a: As Option 2 but with multiple sub-surface hubs
- **Option 3:** Radial arrangement with sub-zones strung along main cable
    - Option 3a: Passive offshore hub
    - Option 3b: Multiple 33kV cables to shore.

57. A detailed assessment of each of these options was undertaken within the Morlais Preliminary Design Options Report (ITPE, 2018). Option 1 was the overall preferred option for a project of this scale. It offers the most flexibility to the Morlais developers and would fulfil many of the points raised throughout the developer consultation exercise. It represents the least technical risk out of all the options as no unproven technology will be deployed. Furthermore, most of the active electrical systems will be located onshore thus further reducing the risk, operation and maintenance (O&M) costs and minimising reliability issues.

58. Option 2 and Option 3 were not deemed to be suitable as a feasibility basis for this project.

3.9.3. Export Cable Corridor Route Options

59. In parallel with the ECC route selection, three landfall options were identified from the search areas, Abraham's Bosom, Porth Dafarch and Holyhead (Soldier's Point), based on a review of offshore constraints.

60. Following this assessment, high-level routes were identified based on the following parameters (**Figure 3-1, Volume II**);

- Nine separate cable tails installed through the landfall by HDD;
- Eight subsea export cables connecting the Morlais tails to developer projects deployed within each sub-zone; installed independently;
- Separation of 10 m between HDD entry points;
- Separation of 20 m between HDD exit points;
- Cable tail length would be equal to the water depth multiplied by three, plus an additional 5 m buffer;
- Avoiding the worst of the seabed features, and slopes of more than 10 degrees; and
- At least 10 m separation between cables where possible.

61. The Morlais Substation Location Feasibility Study (ITP, 2016) provides an initial assessment of the potential offshore cable route, taking into consideration ground conditions and seabed hazards. Due to the hard and rocky nature of the seabed at the Project site, cable burial is not viable along the offshore sections of the export cable routes.

62. Gradients and complex bathymetry are likely to mean that even surface laid cables will be at risk of moving or sliding if laid across these gradient slopes. Cables in this position could slide and become snagged on rocks, potentially leading to cable damage and failure through abrasion and wear. This is particularly relevant for the cables in the Morlais project as they are being

installed in a high current environment. In addition, the complex bathymetry could result in suspensions due to the inability of the cable to conform to bottom irregularities. Large suspensions could also lead to potential cable damage through strumming, abrasion and wear.

63. Selection of cable protection will be based on the site-specific hazards expected in the MDZ (i.e. fishing). This is especially important as the admiralty charts show an anchorage area close to the landfall locations. Where possible, steep gradients will be avoided, and cables laid in line with the tide to minimise cross current effects. This will in part be mitigated against by careful positioning and routing of the cables.

3.9.4. Refinement of Export Cable Corridor

64. In parallel with the ECC refinement, Menter Môn were undertaking a detailed feasibility of the landfall point and landfall substation location, described further in **Section 3.10**. This resulted in three preferred landfall options at Abrahams Bosom; known as Option 1, Option 5a, Option 8 (and Option 8a). The refined area of the export cable corridor is shown in **Figure 3-3 (Volume II).** Porth Dafarch and Holyhead (Soldier’s Point) were both discounted due to reasons associated with the landfall point and onshore cable corridor, in conjunction with the long export cable corridor routes from the MDZ compared to the Abrahams Bosom option**.**

65. Soldier’s Point (search areas V, W, X, Y on **Figure 3-2, Volume II**) was discounted due to the proximity to the Breakwater Country Park and the high visibility from most locations within the Park. The area was also discounted, as indicated in **Plate 3-2**, due to the disruption to the main town of Holyhead associated with the installation of the onshore cable route selection within the road network.

Plate 3-2 Onshore cable route options to Grid Connection

66. The Porth Dafarch search areas (N, R, Q, S, U on **Figure 3-2**, **Volume II**) included Porth Dafarch beach, which is owned by the National Trust. This sheltered sandy beach is very popular, especially divers as there is a wreck of a cargo ship lost in 1886 (SS Missouri) a short distance from shore. The beach also has a subsea communications cable buried within it and there would not be sufficient space to avoid this cable. A number of constraints were present, such as;

- Narrow inlets in the area give little room for cable landfall;
- Areas of steep and high ridges to the south west of the South Stack Cliffs Nature Reserve requiring the cable to route around and therefore require a longer offshore cable route than most other options;
- The area is fairly visible with little natural screening available in some cases;
- Rock cutting or blasting required to bury cables where minimal sediment cover on beaches.

67. The Cable Routing Report (ITPE, 2018) provides a detailed review of both the offshore and onshore cable routes for the Morlais project. The Project will install up to nine export cables connecting the Landfall Substation to the offshore arrays. An overview of each route is provided in **Section 3.9.4.1** to **3.9.4.3** below.

3.9.4.1. Routes from Landfall Option 1

68. The total length of the nine zone export cables (to the easternmost boundary of each subzone only) is approximately 31 km with this option.

69. Up to 120 individual rock bags or concrete mattresses is estimated to be required for this option.

70. This route uses the most northerly landfall of the three options. It presents slightly more cable installation challenge as the Horizontal Directional Drill (HDD) exit points are furthest into the bay and the sub-zone export cables require routing round the complex bathymetry to the north of the bay.

3.9.4.2. Route from Landfall Option 5

71. The total length of the nine export cables (to the easternmost boundary of each subzone only) is approximately 30.5 km with this option.

72. Up to 120 individual rock bags or concrete mattresses is estimated to be required for this option.

73. This route uses the central landfall of the three options. It has the shortest total HDD drill length and although the drill exit points are far into the bay, they are in the middle, emerging into a relatively flat area, allowing good routing options towards the MDZ.

3.9.4.3. Route from Landfall Option 8

74. The total length of the nine export cables (to the easternmost boundary of each subzone only) is approximately 27.5 km with this option.

75. Up to 120 individual rock bags or concrete mattresses is estimated to be required for this option.

76. This route uses the most southerly landfall of the three options. The HDD exit points are furthest out into the bay at presents a good line for the most northerly routes/cables.

3.9.4.4. Selected Offshore Cable Route

77. This study was undertaken in parallel with the identification of landfall substation location, which is described fully in **Section 3.10** and should be read in conjunction with this Section (**Section 3.9**). From this assessment, Option 1 is the preferred landfall option based upon proximity to the preferred landfall substation location. The ECC presented in **Figure 3-3** (**Volume II**) illustrates the area within which each export cable will be positioned from each array, along the coastline where necessary and into Abrahams Bosom.

78. The final export cable route will be undertaken at the detailed design stage, utilising fine scale geophysical data. These may be installed either as a continuous export cable from onshore substation, each cable installed by a tenant to the Project or as a cable tail installed from the onshore substation to a location several hundred metres and each up to 620 m long. Each ‘tail’ would be terminated in the near shore of the export cable corridor, shortly after the ‘break out’ of planned HDD or trenching.

3.10. IDENTIFICATION OF LANDFALL AND LANDFALL SUBSTATION LOCATION

3.10.1. Site Feasibility and Screening

79. The cable landfall point for a tidal project is a critical part of the whole project; not only does it determine the length of the export cables in the subsea environment, but to a large extent, the approximate location of the landfall substation. This is because the landfall substation should be

as close as possible to the landfall point to reduce the distance the nine export cables would be laid onshore. This study was undertaken in parallel with the identification of the ECC, which is described fully in **Section 3.9** and should be read in conjunction with this Section (**Section 3.10**).

80. The initial desk-based search focussed largely on landfall sites, with associated substation locations identified nearby. A site visit to each of those locations was then undertaken. Important factors that were considered in the initial selection / screening of the cable landfall and substation sites are shown in **Table 3-3**.

Table 3-3 Key Considerations for Screening of Cable Landfall and Substation Site Selection

Factors	Criteria	Comments for Screening of Sites
Inter-project aspects	▪ Minimise the distance from landfall to the substation location ▪ Availability of space to locate an onshore substation, laydown and construction areas ▪ Consideration of likely grid connection points ▪ Ease of access to the substation and landfall site particularly for construction and delivery vehicles ▪ Subsea cable route length and challenges	▪ Preference for substation to be less than 1 km from landfall, to minimise extent of disruption ▪ Ease of access to the substation and landfall site for construction and delivery vehicles important, particularly to minimise disruption on Holy Island's minor roads ▪ Factors affecting the subsea cable route considered include; distance from the MDZ site; sea bed topography; water depth and ground conditions in the area immediately offshore from landfall
Physical baseline	▪ Avoid very high cliffs, hard rock strata and uneven and rocky ground ▪ Flood risk constraints	▪ The coastline in the search area has very few areas that are not high or has steep cliffs and the bedrock is extremely hard. ▪ Hard constraints for the search were taken as cliffs with a height above 50 m and extremely rocky or steep ground, thus the majority of the South Stack Cliffs Nature Reserve was excluded.
Environmental baseline	▪ Onshore nature conservation designations are generally avoided where possible ▪ Marine sensitivities to be considered for offshore cable route required to make landfall option ▪ Natural screening potential	▪ The search area has a large number of designated areas including Special Protection areas (SPAs), Special Areas of Conservation (SACs), AONBs, and Sites of Special Scientific Interest (SSSI) designations, as well as local nature reserves and a Country Park ▪ Marine sensitive areas that the route will cross such as environmental designations and fishing grounds minimised ▪ Designations could be avoided except where there existed a particularly attractive landfall or substation site

Factors	Criteria	Comments for Screening of Sites
Socio-economic baseline	▪ Proximity of residences ▪ Cultural heritage designations	▪ The majority of the Holy Island headland is covered by the Holyhead Mountain Heritage Coast

81. The desk-based search for suitable cable landfall and onshore landfall substation locations used Ordnance Survey maps, as well as aerial photography from Google Earth and Bing Maps. GIS data on environmental and cultural designations, sensitive habitats, landscape quality, coastal features, elevation, geology, bathymetry and seabed characteristics, flood risk and other constraints (such as proximity to residences) were also mapped for the search area. Additionally, considerations such as access and technical feasibility of likely construction methods were also applied to each potential location.

82. The search identified 15 possible landfall locations, with 13 associated possibilities for landfall substation locations identified. Two locations allowed the possibility of co-locating the landfall and substation (search area ‘B’ and ‘N’). All potential locations and routes were visited by the project engineering team. Landfall sites were also viewed from the sea during a vessel-based search. Each potential area is illustrated in **Figure 3-2 (Volume II)**.

3.10.2. Landfall Construction Options

83. The nature of the coastline at the landfall site is a key consideration in determining how landfall is achieved. An ‘open cut trench’ is the standard method of achieving landfall for offshore energy projects; however, this requires a generally flat coast and route to the onshore substation / control room location.

84. HDD is the preferred construction method proposed for the landfall, given the presence of cliffs, reefs, dunes and other sensitive habitats as well as hard rocky strata. However, the use of ducts or J-tubes pinned to the cliff and laid in a trench / slot are also assessed within the EIA, as a back-up should HDD be found to be technically infeasible at a later stage.

3.10.3. Site Short-Listing

85. Between June and October 2016, ITPE carried out a feasibility study to identify possible landfall and substation locations for the Project. The site visits and walkovers entailed an assessment of space, land cover, visibility, possible ground conditions, land stability issues and constraints to development, as well as confirming features, elevations and measurements on maps. Proposed cable routes and possible access routes were driven and areas of difficulty such as tight corners and narrow sections assessed. During the site visits, soil probing was also undertaken across the search areas visited to give an indication of the depth of soil for cable trenching, in conjunction with the use of soil cover maps from the NERC (Natural Environment Research Council).

86. Using exiting information and new knowledge gained from the site visits, the GIS system and a comparative costing exercise, as well as further assessment against all of the technical requirements and constraints, the list of sites was refined. A comparison between the potential onshore infrastructure locations was undertaken taking into account the following:

- Nature Conservation Designations;
- Sensitive habitats and environments;
- Considerations for substation location (e.g. space, proximity to residences, amenity and sensitivity of surrounding area);
- Ease of (and options for) landfall;
- Able route between landfall and substation;
- Ground conditions;
- Route to grid connection;
- Subsea cable route (length as well as possible installation concerns);
- O&M considerations; and
- Costs.

87. At the time, the outline design and construction method statement for all options was based on the following assumptions:

- 12 cable runs offshore – 12 cables will be laid individually, cables would be bundled for installation. Eight cables will require fewer runs;
- 12 HDD routes are required – for 24 cables, two cables will be pulled through each duct. Eight cables will require fewer drills;
- A transition pit is required for all cases where HDD is undertaken to joint subsea cables to land cables. A maximum of three cables are jointed in any one pit;
- Cables are laid approximately 800 mm apart in the onshore trench, requiring a 20 m wide trench for 24 cables; and
- Offshore cable tails are installed upon the seabed, to a distance of several kilometres offshore.

88. A full assessment of the landfall and substation search areas shown on **Figure 3-2** (**Volume II**) was conducted. A summary of the key constraints and outcomes is provided in **Table 3-4**.

Table 3-4 Long List of Landfall and Substation Search Areas

Search Area	Project Area	Description	Assessment
A	Substation	Consists of 11 fields and some small pockets of heathland	▪ The area closest to South Stack Road is sloping and highly visible from many viewpoints. To the north of those five fields there is an area adjoining Welsh Water reservoirs. This location is up to 1 km from the landfall point.
B	Substation	Consists of five sloping fields at cliff top overlooking Abrahams Bosom	▪ The site is in an exposed location is situated on high cliffs which adjoin the South Stack Cliffs RSPB Reserve, and the Holy Island Coast SSSI, SAC and SPA.

Search Area	Project Area	Description	Assessment
			▪ The cliffs to the south of the area appear to be variable in nature, with some areas of visible landslip, making this more less technically feasible for HDD works.
C	Landfall	Consists of two fields, between South Stack Road and the coast	▪ There are higher cliffs than most of the preferred landfall locations which also appear to be variable in nature, with some areas of visible landslip, potentially making this more challenging for drilling. ▪ Drill setback required for cliff height likely to make this option less technically feasible. ▪ The site is close to residences.
D	Landfall	Consisting of a single large field	▪ The is situated slightly further from the coast than other search area option and offers better prospects for achieving landfall.
E	Landfall	Consists of six fields and high cliffs	▪ Drill setback required for cliff height would severely restrict the space available to undertake the number of drills required, making the works less technically feasible.
F	Landfall	Single field separated from the cliff by the coastal road	▪ Search area is situated within the South Stack RSPB Reserve. ▪ The rocky seabed in the immediate vicinity is likely to require a slightly longer drill than other areas
G	Landfall	Two large fields	▪ Search area is situated within the South Stack RSPB Reserve. ▪ The cliff is higher in the area than the surrounding areas, this area will require a longer set-back distance than others, placing restrictions on the potential drill locations. ▪ A longer drill would be required (to the west) due to protruding rocks in the sea at the foot of the cliff.
H	Substation	Consists of a total of 12 fields surrounding farm building	▪ Two of these three areas may potentially have issues with water levels as they adjoin wetlands ▪ The area to the north of the main residence is quite visible from many viewpoints in the surrounding area. ▪ The location closest to the house has mounds of earth / rock on two sides, allowing for some natural screening for the substation. ▪ The location does not lie adjacent to the landfall point
I	Landfall	Consists of four adjoining fields	▪ Search area is situated within the South Stack RSPB Reserve. ▪ Adjoins a potential substation area, offering a very short onshore trench and the possibility of avoiding

Search Area	Project Area	Description	Assessment
			the need for transition pits by taking the subsea cables directly to the substation. ▪ The fields next to this potential landfall point are steeply sloped and quite visible from other viewpoints. Drills may have to be directed in a more westerly direction than straight out to sea to achieve sufficient setback. ▪ This landfall option offers one of the shortest possible subsea cable routes, broadly similar to the Abraham's Bosom option.
J	Substation	Consists of two fields adjacent to residential property	▪ This area is also close to a caravan park as well as adjoining the South Stack Cliffs RSPB Reserve and Holy Island Coast SSSI, SAC and SPA ▪ There is limited space for a substation and is highly visible from the surrounding area. ▪ The nearest landfall point is very close, approximately 400 m.
K	Substation	Consists of seven fields	▪ There are multiple options within this location that could be suitable and is quite well obscured. ▪ There are three landfall possibilities for this location.
L	Substation	Consists of a single field	▪ Site is within close proximity to Standing Stones heritage asset. ▪ The site is raised and on a slight gradient which makes it quite visible to the surrounding area. ▪ The nearest landfall points are at a distance of approximately 900 m to 1200 m.
M	Substation	Consists of two fields	▪ The site is higher in altitude than surrounding land and therefore quite visible. ▪ Site is also further from the coast than nearby alternatives.
N	Landfall and Substation	Consists of three fields and a narrow inlet	▪ The cliffs in this immediate area are low and this location is relatively obscured, however the Isle of Anglesey Coastal Path passes through the area. ▪ This inlet is within the Holy Island Coast SSSI, SAC and SPA designations and the steep bank to the north would need to be excavated for the trench. ▪ If HDD works were undertaken, the rock appears to have weak layers crossing the drill path causing eroded areas visible along the side of the inlets. ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.

Search Area	Project Area	Description	Assessment
O	Substation	Consists of four fields	▪ The fields in this area are fairly visible from the surrounding area. ▪ Situated to the north west of Porth Dafarch Beach adjoining the coastal road.
P	Substation	Consists of four fields	▪ The eastern most corner of this area offers a well obscured location ▪ Lies approximately 700 m to 800 m to the north east of Porth Dafarch Beach. ▪ The site is a long distance from the nearest landfall locations which are both challenging and would require a long onshore trench.
Q	Landfall	Area includes Porth Dafarch beach; owned by The National Trust.	▪ This sheltered sandy beach is very popular, especially divers as there is a wreck of a cargo ship lost in 1886 (SS Missouri) a short distance from shore. ▪ The beach also has a subsea communications cable buried within it. ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.
R	Landfall	Consists of a single field	▪ A long drill will be required in order to achieve landfall as the ground conditions are difficult due to little flat / even grounds. ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.
S	Landfall	Area of field and including the Porth y Corwgl beach	▪ Gentle gradient from the beach, however there is minimal sediment cover. ▪ This area offers the prospect of landing the subsea cables with no drilling ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.
T	Substation	Several fields to the north east of Porth y Corwgl	▪ The Western site boundary is adjoining the Holyhead Golf Club ▪ The furthest north east corner as this portion of the site is well obscured, however there are a number of residences within close proximity to the site.

Search Area	Project Area	Description	Assessment
			▪ The nearest landfall is approximately 550 m to 1000 m
U	Landfall	Area of land between two beaches	▪ This area offers the prospect of landing the subsea cables with no drilling ▪ As there is minimal sediment cover on either of these beaches; rock cutting or blasting will be required to bury cables if surface laying would not be acceptable at his location. ▪ This area is within close proximity to many residences; it would be difficult to route a wide enough cable trench through houses, and/or along the narrow road to the nearest substation location. ▪ Porth y Post beach has a subsea communications cable installed within it; although it is unclear whether this is still in use. ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.
V	Landfall	Consists of three fields and cliff top land	▪ A wastewater treatment works outfall pipe (WwTW) was previously installed in this area. As work was previously undertaken at this site, the ground conditions are known. ▪ This site is located within the Breakwater Country Park and is highly visible from most locations within the Country Park. ▪ The cliffs along this area is relatively low which means there could be many drill locations at this wide area. ▪ Due to distance from the MDZ, this option will require longer subsea cable route.
W	Landfall	The pebble beach immediately to the west of the Holyhead breakwater	▪ The wide beach offers approximately 100 m of 'useable' width to achieve landfall through open cut trenching. ▪ The beach consists of large cobbles and boulders (upwards of 200 mm in diameter) with a few isolated areas of exposed bedrock. ▪ Due to distance from the MDZ, this option will require significantly longer subsea cable route.
X	Substation	Area is located to the south of Holyhead breakwater	▪ Area adjoins a Stena Line storage shed. There would be no need for change of land use from current industrial use.

Search Area	Project Area	Description	Assessment
			▪ Short distance from landfall point, approximately 200 m.
Y	Substation	Land located to the south of the Breakwater Country Park	▪ This site sits outside the park boundary as well as other designations, however as the area is slightly raised, it is visible from the country park. There is a limited amount of flat space in this search area. The distance to the closest possible landfall point is between 400 and 500 m.
Z	Landfall	Consists of one field and a narrow inlet with a beach	▪ Consists of a beach with approximately 18 m of 'useable' width ▪ This site is within the South Stacks Cliffs nature reserve and was possibly the former site of a lifeboat station. Landfall at this location could possibly be achieved with open cut trenching, ▪ This inlet is within the Holy Island Coast SSSI, SAC and SPA designations and the steep bank to the north would need to be excavated for the trench. ▪ The subsea cable route from the offshore site would have to either cross through or be routed around the area of steep and high ridges to the south west, thus a longer subsea cable route is required for this location.

89. This assessment resulted in 14 different potential options of landfall and substation combinations, comprising seven different landfall sites and nine different substation locations, as summarised in **Table 3-5**.

90. From this, nine options were selected; Option 1; Option 2; Option 5; Option 6; Option 7; Option 8; Option 8a; Option 9; and Option 13. With the exception of Option 13, which is located in Holyhead, all sites are located in areas close to Abraham's Bosom.

91. The outline designs for each of the short-listed options are shown in the Project Design Envelope Definition (ITPE, 2018). Possible outline layouts for each option are available for both a trenched landfall and HDD approach.

Table 3-5 Comparison of Potential Onshore Infrastructure Location Options

Option No. (landfall & substation)	Distance from Nature Conservation Designation (m)[1]					Distance from Heritage Coast Designation (m)	Landfall construction method	Closest residential property (m)[2]	Cable route to substation (km)	Grid connection route (km)	Subsea cable route (km)[3]
	SSSI	SPA	SAC	AONB	RSPB						
Option 1 (D & A)	<10	<10	<10	0	<10	<10	HDD	<100	0.7	8.3	44

Option 12 (N & T)	<10	<10	<10	0	300	<10	HDD	150	1.7	3.5	85
Option 13 (X & W)	<10	<10	<10	700	900	900	Trench	<100	<0.1	5.0	81

[1] Closest distance of either substation or landfall location to nature conservation designation
[2] Closest distance of either substation or landfall location to residential properties
[3] Assuming 12 cables

92. In association with this study, proposed onshore cable routes and possible access routes were also taken in to consideration and areas of difficulty such as tight corners and narrow sections assessed. The selection of the onshore cable route is described in more detail in **Section 3.12** but should be read in conjunction with this Section (**Section 3.10**).

93. Through elimination of the less feasible options, the preferred landfall location was narrowed down to four possibilities, with some variation possible if necessary**.** These are outlined below and shown on **Figure 3-4 (Volume II)**:

- Option 1;
- Option 5a;
- Option 8a; and
- Option 8.

3.10.3.1. Option 1

94. The proposed Option 1 landfall substation was initially positioned in the furthest northern point of the search area identified **(Figure 3-4, Volume II)**. The substation location was considered to be well obscured next to an existing water works. However, the cable routes to grid connection as well as between landfall and substation were considered to be long and therefore other substation locations closer to the landfall were explored for this option.

3.10.3.2. Option 5a

95. The proposed Option 5a landfall and landfall substation is located far from roads and most designations and is a well obscured location. However, there are access issues and challenging ground conditions with possible flood issues. The space is also very small. The landfall is outside of the RSPB reserve, but very close to the boundary. The steep cliffs and then gradually sloping seabed also make HDD more challenging. Multiple landowners are present and initial discussions identified that some were not supportive. Therefore Option 5 was not taken forward for development.

3.10.3.3. Option 8 and 8a

96. The proposed landfall for Option 8 has a very short cable route to the proposed landfall substation location, which is the most accessible and one of the best prospects for connection to the onshore cable corridor. However, the substation was considered to be very visible and in close proximity to residences. Therefore Option 8 and 8a were not taken forward for development.

3.10.4. Refinement of Landfall and Substation Locations

97. As outlined above, Option 1 for the landfall location was the option selected on the basis of landowner support, minimising visual impact and technical feasibility.

98. Further refinement of the landfall substation location has been undertaken since the FEED study undertaken by ITPE. Black and Veatch Ltd. (B&V) have been responsible for the further design

of the onshore infrastructure within the ODA, including the landfall substation. Micro-siting of the landfall substation within the search area shown on **Figure 3-4 (Volume II)**, was undertaken in parallel with the completion of the EIA. Due to the position of the substation within the AONB, the potential visual impact was an important consideration. In collaboration with visual impact specialists from IoACC and NRW, a final site was chosen, within a recessive location in the landscape and uses the landform to help integrate the substation into the landscape.

99. Owning to the landfall substation location within the vicinity of the Ty Mawr farm, landowner consultation was undertaken frequently during the selection process.

3.11. IDENTIFICATION OF THE GRID CONNECTION POINT

100. It was assumed that a grid connection at 132 kV would be required. Four possible grid connection points were assessed by ITPE;

- ‘Orthios’ 132 kV connection point;
- ‘Parc Cybi’ 33 kV connection point;
- ‘Valley’ 132 kV connection point; and,
- Caergeiliog 132 kV connection point.

101. The 132 kV grid connection point ‘Orthios’ is the closest suitable 132 kV connection point and there are multiple options for cable routing in minor roads or cross country to minimise disruption during construction. The location is a brownfield site and already developed therefore there would be no significant change to the nature of the surroundings with further development.

102. Although the infrastructure of the 33 kV connection point at ‘Parc Cybi’ is not sufficient to accommodate the full project capacity, this would offer connection to the local electricity network. The location of Parc Cybi offers cable routing along mainly minor roads from all but the Holyhead landfall search area, as well as some potential cross-country routes.

103. The 132 kV connection point ‘Valley’ may be a suitable alternative to Orthios, however there is potential for disruption to major roads if the cable is not to be routed cross country. Valley is also a greenfield site rather the brownfield site (such as the Orthios site). There is possibly slightly better connection point about 700 m to the west, which is the same line into which connection at Anglesey Aluminium would be achieved, albeit some distance further south, and necessitating crossing of the estuary. Owing to the above reasons and the distance from the landfall location, it was considered to be significantly less attractive than the ‘Orthios’ point.

104. The 132 kV connection point ‘Caergeiliog’ is located further south east from Valley. This connection point also offers good connection potential within the existing grid substation site. There would likely be less road disruption than with the nearby ‘Valley’ connection point, although the minor road offering the best option for a cable route is very narrow and appears to support several utilities already. Due to the distance from the landfall location, it was also considered to be significantly less attractive than the ‘Orthios’ point.

3.11.1.1. Selected Grid Connection Point

105. The 132 kV grid connection point 'Orthios' is the most attractive prospect for grid connection for the full scale 240 MW project, being the closest suitable 132 kV connection point to the selected landfall location. There is sufficient space available at the connection point to enable construction of a separate substation and there are multiple prospects for cable routing in minor roads or cross country offering little disturbance to adjacent habitats during construction. minimising of visual impacts was considered in detail during the selection of these sites.

106. In addition, the 33 kV connection point at 'Parc Cybi' is selected as a suitable location for a switchgear building. This would offer connection of early phases of the Project to the local electricity network, whilst the 132 kV grid connection point 'Orthios' is connected to the national transmission network. The two connections provide flexibility in supporting the connection of the Project to the existing electricity supply and in the way in which the Project can best suit the demand for capacity and consumers.

107. In parallel with the completion of the EIA, outline design of a grid connection substation at the 132 kV grid connection point 'Orthios' (hereafter referred to as Grid Connection Substation) and a switchgear building at the 33 kV connection point at 'Parc Cybi' (hereafter referred to as Switchgear Building) has been completed. B&V have been responsible for the further design of the onshore infrastructure within the ODA, including the Landfall Substation.

3.12. IDENTIFICATION OF THE ONSHORE CABLE ROUTE

108. Given the rural nature of the project, the location of the AONB, public perception and consultation with IoACC, it was decided that overhead cables would not be appropriate. The cables will be trenched into the local road network, so much as is practicable to avoid impacts to adjacent habitats during construction and will minimise disruption to local landowners.

109. The route options were broken down into segments because there are multiple options for certain sections of the route, therefore many permutations of options are possible to form the overall route. An overview of the segments of the route is illustrated in **Figure 3-5** (**Volume II**).

110. The segment approach simplifies the overall assessment by allowing each segment to be assessed and added separately. The onshore cable route feasibility was undertaken in parallel with the landfall site selection and therefore these shortlisted route options were selected based on the anticipated likely landfall locations, Option 1, Option 5a and Option 8 and 8a. The assessment was refined during the full site selection process and the final route selection is based on the selection of Option 1 as the preferred landfall option.

111. The Segment 1 options provide a route from the expected landfall area substation to the Switchgear Building shown on **Figure 3-5** (**Volume II**). The Segment 2 options connect Segment 1 to the Grid Connection Substation **Figure 3-5** (**Volume II**).

112. Segment 3 covers the possible cable route options from the 132kV Orthios substation to the 132kV overhead lines at Valley. Due to the grid connection point at Valley being discounted early in the site selection process (as described in **Section 3.11**), Segment 3 is not considered further in this section, although initial feasibility options for access were assessed (**Table 3-6**).

Table 3-6 Onshore cable route Segment 3 options

Option	Description
A5 Stanley Embankment	▪ From the Orthios site, this route follows east and picks up the A5 across the Cymyran Strait, utilising either the road itself, the pedestrian pathway alongside it, or the existing services trench adjacent to the pedestrian path. ▪ The route turns north to the Valley connection site either in the first field east of Stanley Embankment, at Gorad Road, or at the A5025 road.
A55 Expressway Bridge	▪ From opposite the Orthios site, south side of the railway, this route follows east through the A55 across the Cymyran Strait. ▪ On the east side of the straight the route follows north through fields to pick up the eastern end of the A5 Stanley Embankment option.
HDD under the Cymyran Strait	▪ An alternative option for Segment 3 would be to HDD under the Cymyran Strait. ▪ The crossing would be over 1,500 m in length. ▪ An HDD of this length is beyond the normal range of HDD and this could also introduce issues with excessive pulling forces exerted on the cables. ▪ Entry and exit compounds would be required on either side of the strait and no area is apparent on the west side other than Orthios itself. Due to the unlikely feasibility and appetite for this option.

113. For Segment 1, the preferred option is the Porthdafarch Road and Holyhead Leisure Centre. This route option appears to be feasible and has clear advantage over the alternatives which would pass through or near to residential areas and narrow roads within Holyhead town.

114. For Segment 2 the preferred route is along the A5153 and the A5 London Road, or to access the Grid Connection Substation from a location near the Switchgear Building and to the south of the A55 using HDD.

115. A qualitative assessment of the route options for a given cable route segment has been undertaken to understand the issues and challenges for cable installation. The route was divided into three segments representing possible connection to three different connection points: Parc Cybi, Orthios and Valley. The following criteria were considered for each option;

- **Space** – refers to the general space or corridor width available for cable construction works along the route. It also includes localised width restrictions such as bridge crossings, or areas where land use, geology, infrastructure, or environmentally sensitive areas restrict the width for construction. This also considers related health and safety risks such as working in narrow roads with heavy traffic or working near livestock or overhead electricity lines. The availability of any verge adjacent to the road has been included for consideration, where possible, and whether any close settlements or structures are built up alongside the road, which would prevent use of the verge for construction or the cable trench.
- **Obstacles** - localised constraints which the cable route would need to cross via open cut trenching, or in some instances more specialised methods, such as cable bridges, auger boring or by HDD. Obstacles could be, for example, railways, major roads (such

as A or B roads), bridges, watercourses, and small woodlands or rough terrain, or services. A view has been provided on health and safety risks such as where the cable route crosses electricity lines or similar.

- **Services** – whether additional crossings are required to avoid assets such as underground electricity cables, gas pipelines, telecommunication lines, and water or sewage mains. The presence of other services affects useable installation space, disruption of works, technical feasibility and impacts on health and safety.
- **Access** - ease of access for construction, such as distances for parts of the cable route from major transportation arteries such as A or B roads, freight lines, or ports, or through roads with significant weight, width or height restrictions. Health and safety risks have been considered such as if dangerous vehicle movements are required for construction.
- **Environmental constraints** – consideration of ecological and land use constraints, including nature conservation designations, minimising disturbance to adjacent habitats, species, landowners, avoidance of archaeological and heritage assets.

3.12.1. Route Segment 1

116. **Table 3-7** contains the options for Segment 1 of the onshore cable route. These options follow public highway from the landfall to the Parc Cybi area

Table 3-7 Onshore cable route Segment 1 options

Option	Description	Assessment
South Stack Road	▪ From the landfall substation area, this route follows South Stack Road to the northeast to Holyhead. ▪ From there the route follows roads in town to connect to Kingsland Road. ▪ The route follows Kingsland Road to the A5153 and Parc Cybi road. ▪ The route crosses to the north of the A55 at a point near the Parc Cybi 33kV substation. ▪ The route follows along the north side of the A55 to Orthios substation.	▪ This is a two-lane road and appears to have space for a cable trench. ▪ There are hedgerows close to the north side of the road and residences with pavement, a stone wall and lighting services along the south side of the road. ▪ Through parts of the town there is pavement and stone wall on both sides of the road. ▪ There appears to be services in the road (water and drainage) and services which cross the road overhead. ▪ To the North approaching Holyhead, installation through this area is likely to be very disruptive for residents. There is likely to be several services in the road which presents a risk that there will not be enough space for the cables. ▪ From here the route follows the A55 then Kingsland Road which are two-lane roads. Several roundabouts would need to be negotiated. Kingsland Road passes through a built-up residential area with pavements either side.

Option	Description	Assessment
Plas Road	▪ From the landfall substation area, this route follows the road along the coast to Penrhosfeilw, then Plas Road to the northeast to Holyhead. ▪ The route would need to go through some narrow roads near Holyhead to join Kingsland Road. ▪ The route follows Kingsland Road to the A5153 and Parc Cybi road. ▪ The route crosses to the north of the A55 at a point near the Parc Cybi 33kV substation. ▪ The route follows along the north side of the A55 to Orthios substation.	▪ This road along the southern coast is single lane and flanked by stone walls on either side. ▪ There are several 90-degree bends in the road. ▪ There are certain areas where the road passes residences and there are walls on either side of the road. ▪ Other large portions of the road have a stone wall and hedgerow along its east side and hedgerow/scrub plus overhead service on its west side. ▪ Installation through this area is likely to be very disruptive for residents, likely requiring partial closure for the working section. ▪ The north end of the road follows through Kingsland which is built up with residential housing, where it joins the 'South Stack Road' option which is described above.
Porthdafarch Road	▪ From the landfall substation area, this route follows the road along the coast to Porth Dafarch, then Porthdafarch Road to the northeast to Holyhead where it joins Kingsland Road. ▪ The route follows Kingsland Road to the A5153 and Parc Cybi road. ▪ The route crosses to the north of the A55 at a point near the Parc Cybi 33kV substation. ▪ The route follows along the north side of the A55 to Orthios substation.	▪ Overhead services cross the road at multiple locations. ▪ There is a rock formation very close to the east side of the road for about a 200 m stretch. ▪ There are hedgerows, scrub and stone walls along portions of the road. ▪ The road passes through Caer Bothan and Kingsland. Through this residential section there appears to be a water network in or near the road, the pavement switches to the east side of the road, and there is lighting services alongside the pavement. ▪ Residences are built close to the road. Installation through this area would seriously affect residential access. ▪ There are likely to be services in the road which means there is a risk that space will not be available for the cables.
Porthdafarch Road and Mill Road	▪ From the landfall substation area, this route follows the road along the coast to Porth Dafarch, then Porthdafarch Road to the northeast. ▪ The route turns eastward and follows Mill Road to Holyhead. ▪ The route picks up the A5153 and Parc Cybi road.	▪ Mill Road is a small side road providing access to at least one farm and several residences. ▪ The southwestern end has a wide bell mouth which would facilitate turning the cables through this road. This end is also relatively flat and varying in width between 4 m and 6 m, with several bends in the road but none too severe. ▪ At the northern section of the road, there are more residences, some very close and directly adjacent to the road, with hedgerows up

Option	Description	Assessment
	▪ The route crosses to the north of the A55 at a point near the Parc Cybi 33kV substation. ▪ The route follows along the north side of the A55 to Orthios substation.	against the other side, and some of these land plots are used for animal grazing. Installation would cause significant disruption to the residences close to the road. ▪ There appears to be evidence of a service trench through the middle of the road, and there is an overhead service adjacent to the west side of the road.
Porthdafarch Road and Holyhead Leisure Centre	▪ From the landfall substation area, this route follows the road along the coast to Porth Dafarch, then Porthdafarch Road to the northeast. ▪ The route turns eastward on Mill Road and follows it for 500 m. ▪ At this point the route diverts to the field and follows alongside or through the Holyhead Leisure Centre. ▪ The route picks up the A5153 and Parc Cybi road. ▪ The route crosses to the north of the A55 at a point near the Parc Cybi 33kV substation. ▪ The route follows along the north side of the A55 to Orthios substation.	▪ The route would cut across the field in a north-westerly direction, avoiding the sharp bend in the road. This field appears to be used as a pasture for livestock and there is a field gate access. ▪ The route would cross about 50 m of this field to reach the boundary of the Holyhead Leisure Centre site. ▪ The area to the southwest and west of the site appears to be disused scrubland. ▪ An alternative route would be through the leisure centre road and car park itself, there are the presence of water, drainage or sewage services which would need to be crossed.

3.12.2. Route Segment 2

117. **Table 3-9** contains the options for Segment 2 of the onshore cable route. These options connect the end of Segment 1 and the Parc Cybi area, where the Switchgear Building is to be location, to the eastern part of the Orthios site, where the Grid Connection Substation is to be located.

Table 3-8 Onshore cable route Segment 2 options

Option	Description	Assessment
A5153 and A5 London Road	▪ From near the Parc Cybi area, this route would follow the A5153 to cross the railway utilising the road bridge or the pavement on either side of the road bridge. ▪ The route follows the A5153 through several roundabouts to the A5. ▪ The route follows the A5 to the east side of the Orthios site.	▪ This bridge has a roundabout between the road and the railway bridge sections and is about 20 m wide overall, consisting of a 6-8 m wide lane in each direction and 1-2 m pedestrian pavements on both sides. There is likely to be some low voltage power supply cables in the pavement ▪ From north of the railway, the A5 is one wide lane in each direction and follows around the

Option	Description	Assessment
		north of the Orthios site, providing access for the industrial site and a few small residences. ▪ There is a national cycle path which follows on its eastbound (north) side of the road, separated by about a 1 m grassy verge.
Edge of Orthios Site	▪ From near the Parc Cybi substation, this route follows north and crosses the A55 and railway just to the southwest of the Orthios property. ▪ It follows the southern boundary of the Orthios site, adjacent to the north side of the railway, to the 132kV substation.	▪ There is a wooded area on the north side of the railway directly opposite this location. This route would cross the A55 and railway with HDD from a location east of the wooded area to the southwest corner of the Orthios site. Space seems to be available for HDD compounds on either side. ▪ Several private rail tracks running along the southern side of the Orthios site which are likely to be disused due to closure of the aluminium works. They would require removal to allow space for the cable trench.
A55 North Wales Expressway	▪ From the Parc Cybi substation, this route would either follow in the A55 or in the verge of the A55 to a position opposite the 132kV Orthios substation south of the railway. ▪ The route crosses the railway at this location to the Orthios substation.	▪ The A55 can be reached from Parc Cybi to its north. Through this area the A55 is a dual carriageway with a median of about 4.5 m wide. It may be possible to install the cables through the median, or in one of the lanes. This may require closure of one direction of traffic for access and safe working. ▪ To cross the railway to the Orthios site, the best place for HDD would be from the field just east of the 132kV Orthios substation to the large field on the south side of the A55. Both fields appear to offer sufficient space.

3.12.3. Refinement of Onshore Cable Route

118. Following the above assessment, on option has been progressed from each of the two segments. From Segment 1, the selected onshore cable route follows Porthdafarch Road and past Holyhead Leisure Centre to the Switchgear Building. This avoids the residential areas of Holyhead and minimises disruption to local residents.

119. From Segment 2, the preferred option is to use HDD to cross the A55, avoiding disturbance to the main route between Holy Island and the Isle of Anglesey. This decision was subject to extensive investigation with relevant stakeholders

120. The preferred options for each of the route segments are summarised in **Table 3-9**.

Table 3-9 Onshore Cable Route Preferred Options

Segment	Preferred Option	Notes
1	Porthdafarch Road and Holyhead Leisure Centre	This preferred option for Segment 1 follows public highway for most of the route whilst largely avoiding busy areas of Pont Hwfa, Holyhead and Kingsland. The diversion through the leisure centre would be a good alternative to the north portion of Mill Road, allowing for less disruption to local traffic within Holyhead and a more direct route to Parc Cybi. From Mill Road the route joins the A5153 and on to Parc Cybi road to meet the Parc Cybi site
2	A5153 and A5 London Road	The preferred option for Segment 2 follows the A5153 to cross the A55 and railway utilising trenchless crossing methods. The route follows the A5153 through several roundabouts to the A5, then follows the A5 to the east side of the Orthios campus.

UKC	Under Keel Clearance
UXO	Unexploded Ordnance

GLOSSARY OF TERMINOLOGY

Active hub	Hub containing a transformer, switchgear and possible control equipment.
Axial Flow	Horizontal axis rotors.
Category 1 tidal device	Seabed Mounted Sub-Surface Tidal Devices.
Category 2 tidal device	Buoyant Mid-water Column Tidal Devices.
Category 3 tidal devices	Floating and / or Surface Emergent Tidal Devices.
Cross Flow	Vertical axis rotors.
Multicat	Multi-purpose catamaran workboat for offshore works and transport,
Megaripples	Undulations on a non-cohesive surface produced as a result of the interaction of waves or currents on a sediment surface.
Nacelle	A cover that houses all of the generating components in a TEC, including the generator, gearbox, drive train, and brake assembly.
Passive Hub	Hub containing a busbar joining multiple TECs together.
Screw Piles	Steel piles with helical steel plates welded to the pile shaft in accordance with the ground conditions.
Visually Prominent	A visually prominent tidal device is a tidal device where the large proportion of the support structure is visible above the water, to the extent it is visually prominent, together with ancillary elements such as navigation lights, railings and mast.

4. PROJECT DESCRIPTION

4.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) presents details of the Project Design Envelope (PDE) for the Morlais Project (the Project).

2. The Project will provide a consented area for the installation and commercial demonstration of multiple arrays of tidal energy devices, to a maximum installed capacity of 240 Megawatts (MW).

3. The Project will also provide permanent communal infrastructure through the provision of electrical infrastructure, including substations and onshore electrical cable route to grid connection. The Project is being developed by Menter Môn Morlais Limited (hereafter 'Menter Môn'), a not for profit social enterprise company. When consented, the Project's infrastructure will be operated by Menter Môn.

4. This chapter describes the following stages of the proposed development for both the onshore and offshore elements:

   - Construction;
   - Operations;
   - Maintenance;
   - Repowering; and
   - Decommissioning.

5. **Figure 1-1** (**Volume II**) shows the location and boundary of the Morlais Demonstration Zone (MDZ) and Export Cable Corridor (ECC). The two areas combined can be referred to as the Offshore Development Area (OfDA).

6. **Figure 1-2** (**Volume II**) shows the location and boundary of the Onshore Development Area (ODA) which includes the landfall site, onshore cable route, substations and grid connection location.

7. The OfDA and the ODA represent the extent of assessment for the technical chapters in this Environmental Statement. This area is larger than the order limits proposed within the TWAO.

8. A Front-End Engineering Design (FEED) study was undertaken by ITP Energised (ITPE) on behalf of Menter Môn in 2018, to provide the proposed design of the project necessary to inform the EIA project description for consent (**Appendix 4.1, Volume III**). Further to a revision of proposed installed project capacity to 240 MW, an addendum to the study was undertaken for the MDZ elements (**Appendix 4.2, Volume III**), also by ITPE. In parallel, Black & Veatch Ltd. (B&V) have been responsible for further design of, and updates to, the onshore infrastructure within the ODA.

4.2. FLEXIBILITY THROUGH PROJECT DESIGN ENVELOPE

9. Consent for a broad PDE is sought, to ensure maximum flexibility in the tidal technology types consented for deployment by the Project. This approach allows for deployment of a variety of

currently available technologies, whilst also allowing for evolution of the designs of tidal devices over time.

10. However, the range and flexibility sought within the consent application has been limited by careful consideration of development scenarios designed to rationalise the likely approach to development and to set workable limits on potential impacts. The PDE approach used in this ES, has been tested in planning law and is often referred to as the 'Rochdale Envelope' approach (see **Chapter 2, Policy and Legislation**).

4.2.1. PDE to Inform Impact Assessment

11. The project description outlined within this Chapter has been used to shape the impact assessments undertaken in this ES. Characterisation of the PDE for the Environmental Impact Assessment (EIA) has focussed on those characteristics known to interact with environmental receptors, i.e. foundations, cables, moving parts and visible components. The approach considers a range of design parameters and identifies the likely worst-case of each parameter, for each specific receptor.

12. To inform FEED studies and provide information for the EIA project description, consultation with tidal device developers was undertaken between 2017 and 2019. The results of this consultation have been used to determine the technical and physical parameters of tidal devices, any requirements for deployment of the tidal devices and the level of interest from device developers in deploying their devices at the Project. Based on this consultation, appropriate devices were used to define parameters in the PDE.

13. Due to the wide range of tidal devices currently available, any specific tidal devices referred to within this document are provided as examples for reference only and should therefore be viewed as representative of several device types which may be deployed by the Project. Review of tidal device parameters has allowed the identification of realistic worst-case parameters for a number of generic tidal device types. These worst-case parameters have been used to define the PDE in terms of both tidal device parameters and realistic worst-case scenarios for the deployment of arrays of tidal devices and for the deployment of the Project as a whole.

14. Following consent award, tidal device developers will be allocated locations or "berths" within the MDZ, within which they will be able to deploy anything from one device to arrays of multiple tidal devices. Repowering is the replacement of one array of tidal devices with another array of tidal devices, normally with a different, newer or / and updated technology. Array deployments will vary in duration; therefore, the allocation of berths may be repeated throughout the life of the Project, as one berth is removed, its capacity within the Project become available, and a new array is then be deployed, either at the same berth or at a different location.

15. The intention is that the flexibility within the PDE, carried forward into the EIA and reflected in appropriate consent conditions, will allow the Project to encompass many current technologies as well as future technological development. This allows for continued development of tidal devices, their infrastructure and its management, in areas such as:

- Tidal device installation techniques;
- Health and safety;

- Operation and maintenance (O&M); and
- Improved efficiency and reductions in the cost of energy.

16. Consideration of a broad PDE during the EIA and a flexible consent is particularly important in the following areas:

- The total number of tidal devices deployed within the MDZ;
- Layout of tidal devices within the MDZ (location, density, array spacing);
- Device types;
- Foundation/mooring types;
- Location of electrical hubs and monitoring equipment;
- Number and routing of inter-array and export cables; and
- Location and lighting/marking requirements of navigational aids.

4.2.2. PDE Refinement During the Detailed Design Stage

17. To support a variety of tidal device types within the Project and to accommodate different developer requirements, the shared infrastructure installed by the Project will be as flexible as possible. **Section 4.3.5** details the shared infrastructure that will be installed at the Project.

18. The design of key aspects of parts of the permanent works (onshore infrastructure and offshore export cable landfall) is relatively advanced and refined; whereas, the positioning of marine infrastructure (offshore export and array cables, hubs) will be developed via detailed design work post consent.

19. The design of arrays of tidal devices and related moorings, anchors or foundations will be determined on a case by case basis by the tenants to the Project, prior to deployment of their devices. This will be dependent on the requirements of the device type and influenced by a number of factors, including:

- Physical environmental parameters such as:
  - Depth;
  - Tidal resource; and,
  - Seabed substrate.
- Mitigation requirements identified in the ES and enforced as consent conditions; and,
- Wake effects, depending on the tidal technology and number of tidal devices to be installed.

20. In addition to the flexibility within the MDZ, options are included within the onshore infrastructure to allow flexibility to avoid constraints if identified during pre-construction site investigations. In particular, the ODA, which defines the extent of the Project for EIA purposes encompasses sufficient area to allow the micro-siting of onshore infrastructure if required.

4.2.3. Pre-Deployment Stage

21. Even though site-specific information on these types of factors will be available from the EIA characterisation surveys, final positioning of tidal devices may require additional studies to be undertaken by each tenant prior to construction. Such surveys, if required, could include targeted high definition site investigations for geology and archaeology.

22. The information presented in this chapter has been used to inform the technical chapters contained within the ES and is considered to represent the PDE for use within the EIA.

23. Prior to each array deployment, it is expected that there will be consent conditions requiring documentation to be submitted to the licensing authorities (Welsh Government and Natural Resources Wales, NRW) outlining the parameters of the tidal devices to be installed as well as providing details of the construction methodology, O&M strategy, and the array removal (decommissioning) methodology. This will allow review of each array's characteristics against the consented PDE.

24. A statement of confirming that each array deployment fits within the PDE will be submitted by Menter Môn to the Welsh Government and NRW for approval.

25. The Project will comprise an OfDA including the MDZ covering an area of 35 km^2, combined with an ECC with an area of 4.75 km^2, plus associated onshore infrastructure (see **Section 4.2.4** and **4.2.5** below) contained within an ODA of 1 km^2.

26. The total installed capacity of the project will be no more than 240 MW. The currently programmed life of the project is 37 years, which has been the basis of impact assessments. This period includes time required for construction, commissioning, repowering and decommissioning.

4.2.4. Offshore

27. The MDZ is located to the west of Holy Island, Anglesey. The ECC connects the MDZ to the landfall location at Abraham's Bosom on the west coast of Holy Island. The location, scale and co-ordinates for the MDZ and ECC are shown in **Figure 1-1** (**Volume II**).

28. The seabed across the MDZ and much of the ECC is dominated by outcropping rock at surface and coarse sediment types such as gravel, with consistent boulders overlaying. There are a number of wreck features within and around the MDZ and ECC, but no historic wrecks. No presence of Unexploded Ordnance (UXO) is indicated within the MDZ or the ECC.

29. Water depths across the MDZ reach over 72 m Lowest Astronomical Tide (LAT) in the northwest of the site, with an average depth across the main site of approximately 40 m LAT. Depths within the ECC range from over 38 m LAT to the intertidal at landfall. All depths in this chapter shown as depth at LAT.

30. Throughout the MDZ, megaripples features occur sporadically. However, within the ECC, the area to seaward of the proposed landfall at Abraham's Bosom has an almost linear deposition of finer material across the entrance which is up to 7 m deep in parts. The intertidal (landfall)

area is bedrock interspersed with discrete patches of barren shingle and occasional areas of sandy sediment.

31. The key components of the offshore works associated with the Project are outlined in the following paragraphs.

32. Tidal devices will be deployed in multiple arrays within the MDZ, to a maximum installed capacity of 240 MW. The tidal devices installed by the Project and within the PDE will have the following key elements:

- A foundation or anchor on or within the seabed;
- A supporting substructure or mooring;
- Tidal Energy Convertors (TEC); and
- Cable connections.

33. Each single array will be comprised of the same type of tidal device (technology type) and located within a discrete location, or berth, within the MDZ. The installed capacity per array is expected to generally be up to 30 MW, but may in practice be greater or smaller than this, being determined by a number of factors including the individual capacity of the export cables supporting each array, the installed capacity of the Project in full, and the requirements of the tidal devices. The installed capacity of individual arrays is not a parameter of bearing upon the ES, and all installed arrays, when summed, will fall within the total installed capacity for the Project of 240MW.

34. For deployment of arrays, the MDZ may be spilt into a series of subzones, with the zones allowing the demarcation of different technology types. Eight indicative subzones within the MDZ are shown in **Figure 4-1** (**Volume II**), however, these indicative zones may be modified to meet the requirements of tenants and regulators. Arrays and associated tenant infrastructure to be deployed in the MDZ are described further in **Section 4.3.1** to **Section 4.3.4**.

35. A phased approach to deployment of the project may be taken, with scale and timeframe of phasing determined by assessments and consideration of mitigation and management undertaken within the ES. Further detail is provided in **Chapter 11, Marine Ornithology**, **Chapter 12, Marine Mammals**, and **Chapter 25, Socioeconomics, Tourism and Recreation**.

36. Dependent on the type of tidal device, full deployment to 240 MW could comprise up to a maximum of 620[1] tidal devices, supporting up to 1,648 TECs and up to 740 inter-array cables within the MDZ. This represents the worst-case scenario as outlined in **Section 4.3.1.2**.

37. Water depths and tidal resource vary across the MDZ. The eight indicative subzones are located in parts of the MDZ that support stronger tidal resource, while also offering a range of depth parameters. Across indicative subzones 1, 2 and 3 approximate water depths are mainly between 30 and 40 m, with some deeper areas of 40 to 45 m, whilst within the majority of

[1] Based on an indicative worst-case maximum deployment scenario of 240MW deployment of arrays of small devices (each device 0.2 to 0.5 MW).

indicative subzones 4, 5, 6 and 7 the approximate water depths are generally in the range 30 to 35 m. Across indicative subzone 8 approximate water depths range from 40 m to 60 m.

38. The MDZ and ECC will also contain the following ancillary infrastructure;

- Up to nine export cables;
- Up to nine export cable tails (shared with onshore components);
- Navigation and environmental monitoring equipment;
- Mooring and foundation structures; and
- Offshore electrical infrastructure, including submerged, floating or surface emergent hubs.

4.2.5. Onshore

39. The boundary for the ODA is provided in **Figure 1-2** (**Volume II**). Landfall will be located within the bay on the western coast of Holy Island known as Abraham's Bosom. Because of the overlap of marine and terrestrial planning jurisdiction in the intertidal, an area of 15,102 m^2 (0.0151 km^2) of the intertidal is shared between the terrestrial and marine areas of the Project. This area will be included in both the Transport and Works Act Order (TWAO), deemed planning permission and Marine Licence applications for consent.

40. The key components of the onshore works associated with the Project include:

- Cable landfall works, including;
    - Up to nine HDD ducts or trenched equivalents,
    - Up to nine transition pits or bays, and
    - Up to nine export cable tails (shared with offshore components).
- A landfall substation at Ty-Mawr (hereafter referred to as 'Landfall Substation');
- A switchgear building at Parc Cybi (hereafter referred to as 'Switchgear Building');
- A grid connection substation at the existing Orthios Eco-Park to the east of Holyhead (the site of the former Anglesey Aluminium works) (hereafter referred to as 'Grid Connection Substation');
- Onshore cable circuits installed between Landfall Substation, Switchgear Building and Grid Connection Substation; and,
- Onshore cable route joint bays (along onshore cable route between Landfall Substation, Switchgear Building and Grid Connection Substation).

41. The landfall consists of exposed rocky shore, backed by a hinterland of coastal heath and farmland. The Landfall Substation location is within currently farmed land, in the area of Holy Island known as Penrhos Feilw. From transition pits or bays, export cables will be trenched to the Landfall Substation. From the transition pits to landfall, HDD is the preferred method for installation of export cables. However, if HDD is not feasible then an alternative method consisting of trenching marine cables from transition pit to shallow subtidal, with installation and pinning of ducting and cables to cliff face using split-pipe.

42. From the Landfall Substation the majority of the onshore cable will be trenched within the existing minor road network (**Figure 1-2, Volume II**). The proposed cable corridor follows South Stack Road, Porthdafarch Road and Mill Road towards the Switchgear Building. The cable will be trenched from the Switchgear Building to the Grid Connection Substation, with a section installed via Horizontal Directional Drilling (HDD) beneath the A55 and the Holyhead to Bangor rail line.

4.2.6. Mitigation

43. During the development of the detailed engineering design, a number of embedded mitigation measures have been included to reduce the potential impacts of the project. Where significant adverse impacts have been identified as a result of the Project, additional mitigation measures are proposed to seek to reduce residual impacts to acceptable (non-significant) levels, full details are provided in the relevant technical chapters (**Chapter 7** to **Chapter 25** and **Chapter 27, Summary**).

44. Those measures embedded into the project design, within both the OfDA and ODA are outlined in **Table 4-1**.

Table 4-1 Mitigation Measures Embedded into Project Design

Project Infrastructure	Embedded Mitigation Measure
MDZ	Preference for the deployment of seabed mounted or buoyant mid water tidal devices in the north of the MDZ to maintain under keel clearance of 20 m or more, as appropriate to large vessels using those parts of the MDZ. Mitigation through the application of the spatial measure shown and defined in Figure 4-1, shown in the purple area labelled “Submerged tidal devices with 20 m Under Keel Clearance (UKC) only”.
	Maintenance of an area inshore of any floating / surface emergent arrays deployed in the MDZ, with a minimum distance of 1 km from floating / surface emergent arrays to the nearest coastline, and within which a minimum Under Keel Clearance (UKC) of 8 m is maintained to allow safe passage of small vessels. Maintenance of a minimum separation distance of 1 km from the coastline to any visually prominent tidal devices, to increase the separation distance between such structures from the coastline. A visually prominent tidal device is a tidal device where the large proportion of the support structure is visible above the water to the extent it is visually prominent, together with ancillary elements such as navigation lights, railings and mast Mitigation through the application of the spatial measure shown and defined in Figure 4-1, where a light blue area is labelled “Submerged tidal devices with an 8 m UKC only”. When combined with the export cable corridor (where no devices are deployed) and shown in Figure 4-1 as a blue cross hatched area, a minimum distance of 1km to shore from any floating / surface emergent array is achieved.
	Mitigation through the preference for the deployment of surface emergent devices in the south of the MDZ. Potential in the future for deployment of visually prominent tidal devices in more northern parts of the MDZ will be kept under review on a case by case basis with regulators.
	Minimising visually prominent elements of the Project as much as practicable within the MDZ to help ensure the composition of offshore elements is as simple as possible.

Project Infrastructure	Embedded Mitigation Measure
	Project Design Envelope for tidal devices defined using parameters available from established tidal device technologies, which has been assumed will be developed sufficiently for commercial use at time of deployment.
	Mitigation by micro-siting and avoidance or modification of construction foundation design for potential channel areas (unless archaeological value confirmed as low).
ECC	Selection of cable corridor to minimise length of export cables within the marine environment.
Landfall Substation	Selecting a recessive location in the landscape, in a relatively low-lying position and using the landform to help integrate the Landfall Substation (cutting into the valley side rather than building a platform out).
	Arrangement of plant and equipment at the Landfall Substation within three buildings, resulting in a collection of buildings that break up the scale of the development and create a form and massing that is comparable with local agricultural buildings.
	Using colours and materials (including natural materials) that are consistent with the vernacular associated with agricultural buildings and are recessive in the local context.
	Using the buildings to define the boundaries of the substation, reducing the requirement for security fencing.
	Considering limited application of planting to help integrate the substation, acknowledging the limitations associated with this in the open and exposed coastal landscape.
	Using stone walls and stock proof fencing as part of new boundaries.
	Minimising the use of external lighting in this rural location.
	A 3.5 m high acoustic demountable fence will be installed around the HDD equipment and a 2 m high solid hoarding fence will be built around the works compound boundary.
Onshore Cable Corridor	Use of underground cabling to provide the connections between all Project elements, avoiding the need for overhead cables.
	Routing the underground cable within the local road corridors to minimise potential disruption to field boundaries.
Grid Connection Substation	Positioning of the substation in a location where industrial structures form an established part of the baseline context, and where established vegetation surrounding the site provides effective visual enclosure.
Switchgear building	Positioning of this element within an allocated employment site, adjacent to an existing substation and where surrounding development will be comparable in form, massing and appearance.

45. Embedded mitigation measures relating to navigational safety in **Table 4-1**, above, are derived from the Navigation Risk Assessment (**Appendix 15.1, Volume III**), undertaken for **Chapter 15, Shipping and Navigation**. These measures are not taken into consideration as embedded mitigation measures within this chapter, due to the requirement to consider only safety measures as embedded mitigation within the impact assessment.

4.3. OFFSHORE INFRASTRUCTURE

46. The key components of the offshore works associated with the Project are detailed in this Section, in the following order:

- Tidal device;

- Foundations;
- ECC and electrical infrastructure (i.e. hubs); and
- Navigation and monitoring equipment.

4.3.1. Tidal Device Envelope

4.3.1.1. Review of Existing Tidal Technologies

47. Based on the developer consultation undertaken over the period 2017 to 2019, significant consideration has been given to which types of tidal devices to include in the PDE of the Project. The device types included in this project description chapter, and therefore assessed in this EIA, are deemed to represent the most realistic parameters for deployment by the Project.

48. Tidal devices comprise of the TEC, the supporting structure, and the anchor or foundation. **Plate 4-1** shows the two forms of TEC that may be mounted on a tidal device, either horizontal axis or vertical axis TECs.

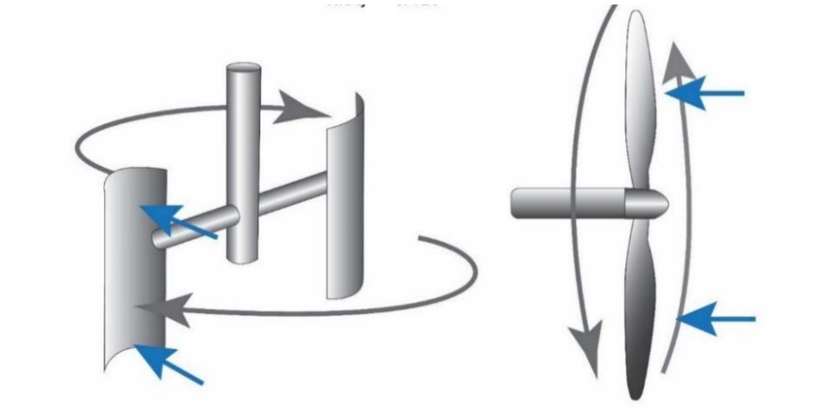

Plate 4-1 Illustration of Vertical (Left) and Horizontal (Right) Axis TEC Types

49. **Plate 4-2**, **Plate 4-3** and **Plate 4-4** show the tidal devices and their respective components, using three generic types of tidal device as exemplars. Note that the actual form of tidal devices and numbers of TECs supported will differ between the technologies deployed.

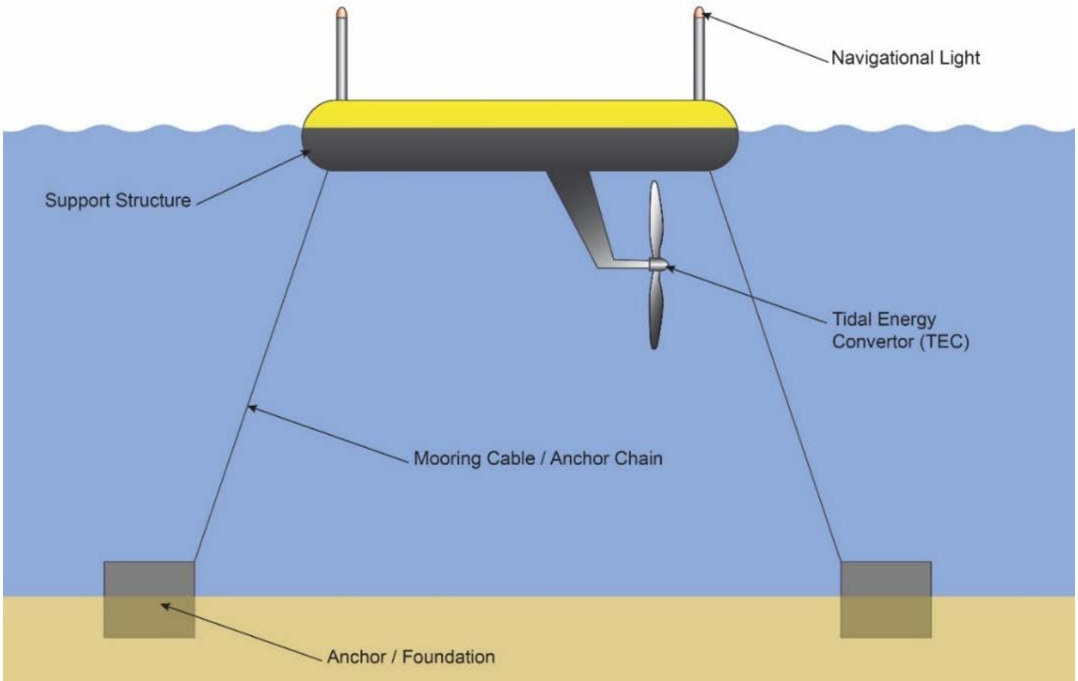

Plate 4-2 Generic Tidal Device Exemplar 1 – Floating or Surface Emergent Tidal Device, Comprised of TEC, Support Structure, Mooring Cables / Anchor Chains and Anchors / Foundations

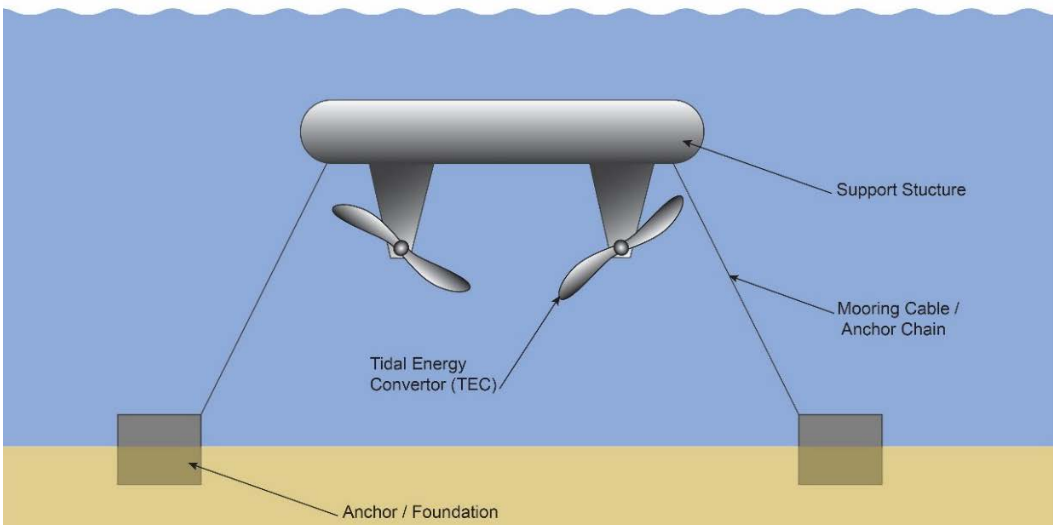

Plate 4-3 Generic Tidal Device Exemplar 2 – Mid Water Column Tidal Device, Comprised of TEC, Support Structure, Mooring Cables / Anchor Chain, and Anchor / Foundation[2]

[2] Note this device is shown facing into direction of current flow

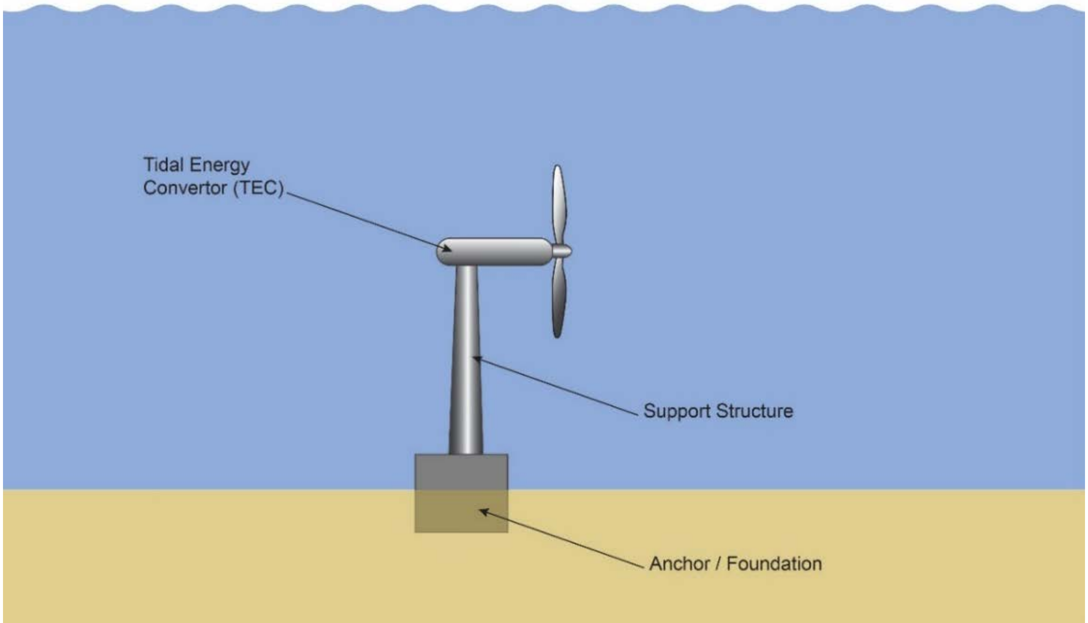

Plate 4-4 Generic Tidal Device Exemplar 3 – Seabed Mounted Sub Surface Tidal Device with TEC Supporting Structure and Foundation

50. The device types considered suitable for the PDE are shown in **Table 4-2**, with example technologies for each TEC.

Table 4-2 Categorisation of Devices for the Project Design Envelope

Sub-Category	Exemplars (Developer or Device Names)	
Category 1: Seabed Mounted Sub-Surface Devices		
Large rotor(s) (>10 m diameter)	▪ SIMEC Atlantis Energy ▪ Andritz Hydro Hammerfest	 Developer: SIMEC Atlantis Energy Source: (https://twitter.com/simecatlantis/-status/534996023178178560

Sub-Category	Exemplars (Developer or Device Names)	
Small (<10 m diameter) rotors	▪ Verdant Power ▪ QED Naval SubHub ▪ Nova Innovation ▪ Sabella	 Device/Developer: Gen5Tidal/Verdant Power Source: Verdant Power  Device/Developer: D10-1000/Sabella Source: Sabella
Vertical axis turbine	▪ Repetitive Energy	 Developer: Repetitive Energy Source: http://www.repetitiveenergy.com/our-technology/

Sub-Category	Exemplars (Developer or Device Names)	
Category 2: Mid-Water Column Devices		
Multiple small (<10 m diameter) rotor upon submerged buoyant platform	▪ SME PLATO platform or similar with Tocardo or Schottel TECs ▪ Renewable Devices Marine Ltd.	 Developer: Renewable Devices Marine Ltd. Source: https://www.theenergytimes.com/ distributed-energy-ecosystem/scots-push-new-tide-turbine-tech
Category 3: Floating or Surface Emergent Devices		
Large rotor (>10 m diameter) floating or emergent devices	▪ Orbital Marine Power ▪ Magallanes	 Developer: Orbital Marine Power Source: https://marineenergy.biz/2018/11/16/orbital-marine-unveils-o2-turbine-blueprints/
Small rotor (<10 m diameter) floating devices	▪ Tocardo TFS	 Developer: Tocardo Source: https://marineenergy.biz/2018/06/06/-tocardo-strengthens-management-with-finance-appointments/

Sub-Category	Exemplars (Developer or Device Names)	
Floating vertical axis devices	▪ Instream	 Developer: Instream Source: https://www.marineenergywales.co.uk/-instream-and-itpenergised-full-scale-demonstrator/
Large rotor (>10 m diameter) surface emergent spar buoy	▪ Aquantis	 Developer: Aquantis Source: https://www.f6s.com/aquantisinc

4.3.1.2. Tidal Energy Convertor Parameters

51. Several representative tidal technologies have been considered in order to capture the likely range of TECs that may be demonstrated within the MDZ. The TECs to be installed will fall into one of two main types as shown in **Plate 4-4**:

- Horizontal axis (axial flow) rotors; or
- Vertical axis (cross flow) rotors.

52. As shown in **Plates 4-1** to **4-3**, the TEC support structure may be:

- Seabed mounted and submerged;
- Buoyant and mid-water column; or
- Floating.

53. The nominal outputs of tidal devices included within the PDE range from 200 kW to 4 MW, with individual devices potentially supporting one or several TECs. The potential output of individual

TECs within tidal devices could range from 50 kW to 2 MW. Tidal devices with a maximum installed capacity value of 2 MW exist, however, it is anticipated that with improvements in efficiency of technologies, devices of up to 4 MW may become available, while all other PDE parameter maximums remain unchanged.

54. Under Keel Clearance (UKC) of devices below LAT will take account of shipping and navigation constraints (as detailed in **Chapter 15, Shipping and Navigation**). Across much of the MDZ the UKC of seabed mounted sub-surface devices or buoyant mid water column devices will be greater than 8 m, however, this may be reduced where a lack of navigation constraints allows shallower deployment of appropriate devices. In deeper parts of the MDZ (in the north and north west of the MDZ), the UKC will be greater to accommodate larger vessel navigation requirements, with the Project maintaining an UKC of at least 20 m below LAT in these areas.

55. Where floating and surface emergent tidal devices are deployed in the MDZ, their physical support structures are present at surface and therefore there can be no UKC. It should be noted, however, that the uppermost point of TECs deployed on these devices will be located several metres below water surface.

56. The number of TECs per device will be typically between one and four, although for some multiple TEC surface platforms this may increase to up to five per device. For those devices, if each TEC is assumed to have three rotor blades, then the maximum number of blades could be 15 for each single device.

57. The number of rotor blades associated with each TEC is typically two or three per TEC, although TECs within the PDE could have up to six rotor blades.

58. The maximum TEC rotor diameter within the PDE is 27 m. Typically, the rotor diameters will be between 10 to 16 m. The area of leading edge per rotor will be between 1.5 and 15 m^2.

59. The average speed of TEC rotation considered within the PDE is between 7.5 and 26.7 rotations per minute (rpm). For smaller (10 m or less in diameter) open rotor devices the average speed of TEC rotation could be between 13.6 and 26.7 rpm. For larger (more than 10 m in diameter) open rotors the average speed of TEC rotation is generally lower, between 7.5 and 10.1 rpm.

60. The PDE allows for a maximum number of individual TECs within the Project to be limited to up to 1,648 TECs spread across up to 620 tidal devices and with a total of 4,750 blades. This assumes the Project at full 240 MW capacity and a deployment scenario which is dominated by devices with larger numbers of TECs per device. The actual number of tidal devices, associated TECs and their rotor blades deployed to achieve 240 MW may be much smaller, but maxima are used here to define the worst-case in this PDE.

4.3.1.3. Seabed Mounted Sub-Surface Devices (Category 1)

61. **Table 4-3** provides a review of parameters for the example tidal technologies outlined in **Table 4-2**, in order to define the worst-case scenario for seabed mounted sub-surface device types in terms of TEC parameters, numbers of devices and swept area. A range of capacities are provided for each device type and the maximum number of devices per subzone is based on the smallest capacity from each range as a factor of a proposed potential array capacity of 30 MW.

Table 4-3 Seabed Mounted Sub-Surface Device Parameters (Worst-Case Highlighted in Blue)

Device Type	Number of devices (in a 30 MW array)	Number of TECs per device	Average TEC speed (rpm)	Max. diameter (m)	Max. device swept area (m^2)	Max. array swept area (m^2)
SIMEC Atlantis Energy	30	1	7.5	26	531	15,930
Andritz Hydro Hammerfest	30	1	7.5	26	531	15,930
Verdant Power	25	3	22	10	235	5,875
QED Naval SubHub	10	3	Assume as Verdant	Assume as Verdant	Assume as Verdant	Assume as Verdant
Nova Innovation	100	1	22	10	78.5	7,850
Sabella	30	1	7.5	15	176.7	5,301

4.3.1.4. Buoyant and Mid-Water Column Devices (Category 2)

62. **Table 4-4** provides a review of parameters for the example tidal technologies outlined in **Table 4-2**, in order to define the worst-case scenario for buoyant and mid-water column device types in terms of TEC parameters, numbers of devices and swept area. A range of capacities are provided for each device type and the maximum number of devices per subzone is based on the smallest capacity from each range as a factor of the largest subzone capacity (30 MW).

Table 4-4 Buoyant and Mid-Water Column Device Parameters (Worst-Case Highlighted in Blue)

Device Type	Number of devices (in a 30 MW array)	Number of TECs per device	Average TEC speed (rpm)	Max. diameter (m)	Max. device swept area (m^2)	Max. array swept area (m^2)
Generic mid water platform with Tocardo TEC	20	5	18	10	392.8	7,857

4.3.1.5. Floating / Surface Emergent Devices (Category 3)

63. **Table 4-5** provides a review of parameters for the example tidal technologies outlined in **Table 4-2**, in order to define the worst-case scenario for floating device types in terms of TEC parameters, numbers of devices and swept area. A range of capacities are provided for each device type and the maximum number of devices per subzone is based on the smallest capacity from each range as a factor of the largest subzone capacity (30 MW).

Table 4-5 Floating / Surface Emergent Device Parameters (Worst-Case Highlighted in Blue)

Device Type	Number of devices (in a 30 MW array)	Number of TECs per device	Average TEC speed (rpm)	Max. diameter (m)	Max. device swept area (m^2)	Max. array swept area (m^2)
Orbital Marine Power and Magallanes	15 (8*)	2	8.71	25	982.1	14,732

Device Type	Number of devices (in a 30 MW array)	Number of TECs per device	Average TEC speed (rpm)	Max. diameter (m)	Max. device swept area (m^2)	Max. array swept area (m^2)
Tocardo (TFS)	20	5	18	10	392.8	7,857
Instream	50**	2	13.6	5	19.92	996
Aquantis	30 (15*)	1	10.1	27m	572.7	17,183

* Values in brackets for Orbital / Magallanes and Aquantis assume a future tidal device with improved TEC efficiency to give up to 4 MW installed capacity per device.

** Values for Instream type device are for a 10 MW array.

4.3.1.6. Corrosion Protection and Antifoulants

64. The majority of devices will utilise some form of corrosion protection system; those proposed are broadly similar to those adopted within other marine industries. These may include systems such as offshore grade protective paint systems, impressed current systems and sacrificial anodes.

65. Structures will typically be painted with modified epoxy or acrylic based abrasion-resistant paints suitable for subsea and splash zone, plus similar primer. Individual devices are each expected to use between 500 and 1,200 litres of paint. All protective coatings and paints used will be suitable for use in the marine environment and, where necessary, approved by the Health and Safety Executive.

66. Impressed Current System (ICS) or sacrificial anodes are both commonly used on ships and subsea structures and may form part of the tidal devices deployed by the Project. Sacrificial anodes are commonly used to supplement the ICS as a back-up or located on parts of the structure where ICS cannot be used. The anodes are standard products for offshore structures, which are welded onto the steel structures and consist of aluminium (98 to 96%) and zinc. The number and size of anodes will vary dependent on device design.

67. Antifoulants may be applied in areas of tidal devices considered particularly susceptible to the build-up of marine growth, for example TECs (rotors and nacelle) and heat exchangers, to ensure devices maintain optimum performance.

68. The majority of antifouling paints produced and available for use in the UK are copper-based, in which the main biocide is cuprous oxide, the natural form of copper. Some antifouling paints contain a less potent form of copper (cuprous thiocyanate) and can be referred to as ‘copper free’ paints. The paints may also contain other biocides in smaller quantities. The use of antifouling paints will be limited to areas of specific need by tenants.

69. A teflon based antifoulant (such as Intersleek 900) has also been commonly used on tidal devices. Intersleek 900 is a non-leaching antifoulant that works by physically preventing species’ attachment as opposed to having biocidal activity.

70. Antifoulant products are generally installed before the first deployment of an array and may be reapplied as required during maintenance activities. A decision on what presents the Best Practicable Environmental Option (BPEO) will be made for each deployment, in compliance with a review of the parameters of each array deployment for compliance with the PDE. The requirements for antifouling may vary between categories of tidal devices.

71. In summary, the following worst-case scenario footprints for the MDZ will be used in the impact assessment:

- Use of sacrificial anodes to each tidal device deployed; and
- Use of copper based anti-fouling paints.

4.3.1.7. Summary of Worst Case Tidal Energy Convertor Parameters

72. Where relevant, technical chapters (**Chapters 7** to **Chapter 26**) of this ES will identify which device type presents the worst-case scenario for their specific receptors. **Table 4-6** below details the worst-case scenario for TEC parameters and device numbers within a 30 MW array, and these values are considered to be within the PDE of this EIA.

Table 4-6 Worst Case Scenario based on Full 240 MW Deployment (Worst-Case Highlighted in Blue)

Parameter	Seabed Mounted Sub-Surface Devices (Category 1)	Buoyant and Mid-Water Column Devices (Category 2)	Floating / Surface Emergent Devices (Category 3)
TEC diameter	26 m	10 m	27 m
TEC speed	22 rpm	18 rpm	18 rpm
30 MW array swept area	15,930 m^2	7,857 m^2	17,183 m^2
Number of devices in a 30 MW array	100	20	50*

* Values for Instream type device are for a 10 MW array, with no deployment of this technology at greater scale within the PDE. This represents the greatest number of floating devices.

4.3.2. Foundation Systems

73. There are two types of foundation systems proposed for use by developers within the MDZ, seabed mounted and anchored (mooring) systems. Within both types there are various options which could be adopted.

74. Anchored devices may be either surface floating or mid water column and buoyant. Seabed mounted foundations in the PDE include Gravity Based Structures (GBS) (including tri-frames), multi-piled structures (including tripods and quadrapod) and monopiles.

75. The worst or 'extreme case' values for foundations and anchors presented below are based on different scenarios of deployment across the site. Each scenario is based on the maximum number of devices that represented a 'worst-case' for potential receptors, whilst assuming no more than 30 MW of any one specific technology. The figures have been calculated based on 30 MW of a technology that represented the 'worst-case' impact, followed by 30 MW of the technology with the second 'worst-case' impact, 30 MW of third 'worst-case' impact and so on until the full potential across the site is reached. It is important to note that more than 30 MW of

any of the device type examples could be deployed in multiple arrays, however, the total worst case calculated will not be exceeded.

76. The values for each technology are based on those provided by developers during a developer consultation exercise and captured in a FEED report commissioned to form the basis for the PDE for the Project (**Appendix 4-1, Volume III**).

4.3.2.1. Gravity Based Structures

77. For some of the tidal devices and infrastructure that may be deployed at the MDZ, the preferred foundation concept is a GBS. GBS utilise the submerged mass of a structure to resist environmental and operational loading on the device and maintain its stability. GBS may be used as foundations or anchors for all three categories of tidal devices included within the PDE, as well as for project infrastructure such as hubs.

78. The footprint (the element of the foundation in direct contact with the seabed) of GBS, proposed within the MDZ would typically be very small (<10 m^2) for each tidal device, with some GBS using 'feet' that focus the weight of the foundation on a small area of seabed. The weight of the foundations can sometimes cause the feet to penetrate the seabed (by up to 0.5 m). The use of feet minimises requirements for seabed levelling as well as also reducing the surface area of the foundation that is in direct contact with the seabed.

79. In a few limited cases some clearing (or grouting) of the seabed might be necessary below a GBS if a sufficiently level area could not otherwise be found. However, this is not anticipated to be widespread.

80. For a 240 MW capacity deployment of tidal devices and supporting infrastructure (such as hubs) using only GBS for foundations and anchors, the total (worst-case) footprint would equate to 74,790 m^2 [3]. The additional seabed footprint (m^2) for navigation and environmental monitoring equipment moorings as well as other project components such as cable protection is defined in **Table 4-24**.

4.3.2.2. Pin Pile Drilled Foundations

81. For some of the tidal devices and infrastructure that may be deployed at the MDZ, the preferred foundation concept is a tripod or quadropod structure typically using three or four drilled pin piles.

82. Due to the hard substrate (bedrock) in the MDZ, drilling will be required to install piled foundations (pin piles or monopiles). For each pin pile a socket is drilled into the seabed,

---

[3] Worst-case GBS footprint based on 240MW deployment achieved using 590 tidal devices with the largest foundation footprints and 120 hubs to maximise footprint, as follows: 120 devices @ 4x36m^2 each; 120 devices @ 2x60m^2 each; 15 devices @ 4x78m^2 each; 20 devices @ 2x78m^2 each; 15 devices @ 4x78m^2 each; 150 devices @ 1x9m^2 each); 30 devices @ 4x78m^2 each; 120 devices @ 1x36m^2 each; 60 electrical hubs @ 4x40m^2 each; and 60 electrical hubs @ 1x100m^2 each.

typically between 1.0 to 2.5 m in diameter and the pin pile is inserted into the socket. The pin pile is then grouted or swaged in place to secure it into the seabed. Some piles will be self-drilling, others will require an annulus to be drilled, of sufficient size to accommodate the pile. This will create spoil arisings from the drilling process.

83. In some cases, screw piles may be used; these are steel piles with helical steel plates welded to the pile shaft in accordance with the ground conditions. Screw piles are wound into the seabed much like a screw into wood, using (temporary) rotary hydraulic equipment. The pile diameters and thus drill arisings are broadly similar to drilled pin piles.

84. For a 240 MW capacity deployment of tidal devices and supporting infrastructure (such as hubs) using only piled foundations the worst-case scenario is total footprint on the seabed would be 5,889 m^2 [4]. The worst-case seabed footprint for piled foundations is significantly less than worst-case seabed footprint for GBS; therefore, GBS will be used as worst-case footprint for impact assessment of seabed impacts.

85. Drill arisings are produced during pin pile installation, with up to 117,780 m^3 [5] generated for the 5,889 m^2 footprint detailed earlier in this section. Disposal of this material would be *in-situ,* directly to the surrounding sea bed. The duration for each will be between two and three days.

86. A total of 1,490 drills will be required for the worst-case outlined above, taking up to 3,990 drilling days to achieve[6].

87. For repowering, an additional 50 % of drilling arisings, footprint and drilling time has been assessed.

4.3.2.3. Monopile Foundations

88. The use of monopiles falls within the PDE, with potential to be used within the MDZ to house electrical hub infrastructure. If they are required, then in a similar way to pin pile foundations, monopiles will be inserted into sockets which have been previously drilled into the seabed and the monopiles then grouted in place. The PDE assumes monopiles which extend up to 18 m above sea surface at LAT may be used. Eight such monopiles (one for each potential subzone within the MDZ) might be deployed, each of 6 m diameter giving a significant internal space for array connection infrastructure.

89. For eight monopiles used to house surface-piercing electrical hubs, the worst-case footprint for monopiles is 226.2 m^2. The worst case seabed footprint value of 74,790 m^2 already includes

---

[4] Worst-case pin pile footprint based on 240MW deployment achieved using 290 tidal devices and 120 hubs to maximise the footprint: 80 devices @ 4 x drills of 2.6m diameter (21m^2) each device; 120 devices @4 drills of 1.2m dimeter (4.5m^2) per device; and 90 devices @ 3 drills of 2.6m diameter (15.9m^2) per device; then 60 large hubs @ 3 drills of 2.6m diameter (15.9m^2) per hub; and 60 small hubs @ 4 drills of 2.6m diameter (21m^2) per hub. Total number of drills 1,490.
[5] Assumes 5,889m^2 footprint of piles and 20m depth of drilling
[6] Total of 1,490 drills, 1.2m diameter drill taking 2 days each, and all other drills taking 3 days each.

hubs assumed to be mounted on GBS foundations. Therefore, this figure of 226.2 m^2 is not additional seabed footprint.

4.3.2.4. Mooring Systems

90. A number of tidal devices utilise a buoyant support structure on which to mount the TECs. These can be held in a fully submerged and mid water column position (**Table 4-2**, Category 2 devices) or have a partially surface emergent support structure (**Table 4-2**, Category 3 devices).

91. Floating tidal devices, typically using catenary moorings are considered in this PDE, with each tidal device requiring four GBS, to which catenary mooring chains are attached. At any time, a portion of the mooring chains will lay upon the seabed and a portion will be suspended. The suspended weight of chains between the GBS and the tidal device keeps the device in position by maintaining a dynamic tension. The amount of chain suspended at any time is adjusted by the movement of the tidal device in response to the tidal state, wider surface conditions, and in particular to wave climate.

92. **Plate 4-5** illustrates the potential use of catenary moorings for one of the floating tidal devices included within the PDE and is representative of catenary moorings generally for floating devices.

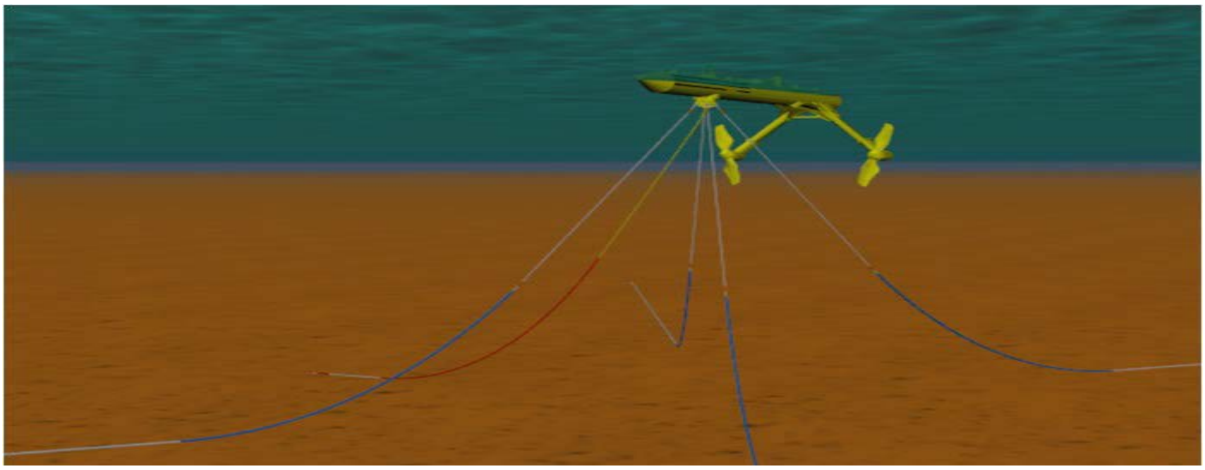

Plate 4-5 Example of Catenary Mooring System (Source: Orbital Marine Power)

93. Buoyant mid-water column devices will typically use a tension mooring system, with the buoyancy of the submerged tidal device holding mooring cables between the tidal device and GBS in constant tension. Such a system does not have to be able to manage surface weather conditions and is subject to less movement than catenary systems, with constant tension maintained on mooring cables as the buoyant tidal device 'seeks' to reach the surface and the moorings restrain it. All cable between tidal device and GBS is in tension and no cable is in contact with the seabed.

94. **Plate 4-6** illustrates and compares catenary and tension moorings.

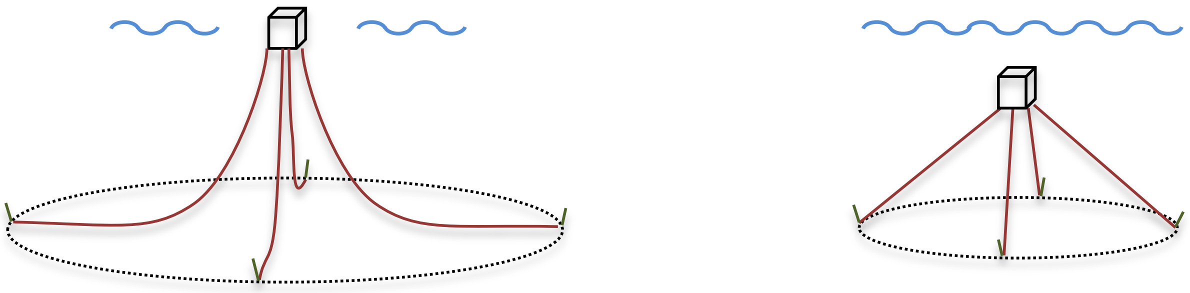

Plate 4-6 Schematic of a Catenary (Left) and a Tension (Right) Based Mooring System

95. The use of catenary moorings for floating / surface emergent tidal devices, leads to a 'Catenary Swept Area' (an area that could be subject to chain drag) where a portion of the mooring chain between a tidal device and a GBS is in contact with the seabed at any point in time. Chains within a catenary mooring system may ‘sweep’ a portion of seabed as the tidal device moves within a window in response to external forces (wind, wave and tides). In these instances, the swept area may be significantly greater than the footprint of the gravity anchors themselves. This effect does not apply to tension moorings as the cables in tension lines do not drag on the seabed.

96. Based on a deployment to 240 MW capacity using only tidal devices that may use catenary mooring systems, the total Catenary Swept Area across the entire MDZ could be up to 2,055,000 m^2 [7].

4.3.2.5. Summary of Worst Case Foundation Parameters

97. A combination of GBS footprint and the use of catenary mooring is the worst-case scenario for seabed footprint of a mooring / foundation system. The worst-case scenario for seabed impact is based on the full 240 MW capacity being installed using 30 MW arrays of tidal devices, using gravity-based foundation systems, with GBS anchor blocks used for floating and mid water devices.

98. The footprint associated with the alternative foundation method of pin-piling device foundations, plus the footprint of associated drill arisings produced by this method are less than the footprint of gravity base foundations. If such foundations are used, their potential seabed footprint impact is considered to be included within that of GBS foundations.

99. Where relevant, technical chapters (**Chapters 7** to **Chapter 26**) of this ES will identify which foundation type presents the worst-case scenario for each receptor. Any devices/arrays with

[7] Worst-case catenary footprint based on 240MW deployment achieved using 410 tidal devices of types which may use catenary moorings to maximise the potential seabed footprint as follows: 30 tidal devices each with catenary swept area of 9,500m^2 each (large devices); 140 devices having swept area of 7,500m^2 each (medium scale devices) floating devices; and 240 tidal devices having swept area of 3,000m^2 each (small scale devices). All catenary footprint measured using CAD to calculate using maximum excursion criteria.

foundation footprints or drill arisings that fall within the worst-case scenarios outlined in **Table 4-7** are considered to be within the PDE of this EIA.

Table 4-7 Worst Case Scenario based on Full 240 MW Deployment

Parameter	Value
Total GBS footprint	74,790 m^2
Catenary or anchor / mooring swept area	2,055,000 m^2
Drilled pin pile foundations	5,889 m^2
Drilled socket arisings	117,780 m^3

4.3.3. Superstructures and Floating or Surface Emergent Elements

100. The MDZ may incorporate floating or surface emergent structures, visible above the sea surface, such as:

- Floating tidal devices up to a maximum of 130 devices;
- Hubs (up to 93 floating hubs or up to eight seabed mounted surface emergent hubs);
- Environmental monitoring buoys (up to 5); and
- Communication and navigational buoys (up to 60 in total) (see **Section 4.3.6**).

101. In terms of maximum dimensions of tidal devices, some of the large rotor diameter floating devices could have lengths of up to 72 m, while other devices, whilst shorter (up to 22 m length), are also wider, with maximum widths of up to 30 m.

102. The supporting structure of tidal devices deployed in the MDZ will not emerge more than 6.5 m above the sea surface at LAT.

103. Electrical hubs may be within surface emergent piled structures which may extend up to 18 m above the sea surface at LAT. The electrical equipment would be housed within the pile.

104. Indicative array layouts used for assessment purposes are detailed further in **Section 4.3.4**. The following summary outlines the number and type of surface emergent devices which could be present across the MDZ and therefore within the PDE of this EIA, with reference to embedded mitigation contained in both Table 4-1 and **Figure 4-1 (Volume II)**:

- Deployment of visually prominent floating / surface emergent devices in the south of the MDZ, to take account of potential for visual impacts. The potential for deployment of floating / surface emergent tidal devices, which are not visually prominent, in more northern parts of the MDZ will be kept under review on a case by case basis with regulators to allow for ongoing development of technology and innovation;
- The worst-case height above sea level[8] for any tidal device will be 6.5 m; and
- The worst-case height above LAT is 18 m for up to eight surface-piercing hub structures.

[8] Note that for a floating / surface emergent tidal device, the device will rise and fall with the tide

4.3.4. Array Layout

4.3.4.1. General

105. The layout of the tidal devices and associated infrastructure (inter-array cables, hubs etc.), will be dependent on the tidal resources across the MDZ as well as the bathymetry and water depths, which the tidal devices require to operate. Therefore, final layout and configuration of visible and fully sub surface elements of the project cannot be predicted. However, based on current understanding of separation distances between certain devices, indicative project layouts can be anticipated and some examples, for illustration purposes only, have been provided (see **Section 4.3.4.4**).

106. Floating devices, which rely on catenary of anchor chains or tension of mooring cables to maintain position will have some movement during changes in tidal conditions, however, this is within the surface area defined by the extent of their anchors or foundations.

4.3.4.2. Device and Array Spacing

107. Array layouts will be identified post consent, following a berth selection and allocation process. Over the life of the Project, layouts will evolve at each new array deployment, or during repowering, when tidal devices within existing arrays may be replaced , or full arrays replaced with new arrays deployed at new locations. The shape of the array layout will depend on the physical requirements of the specific tidal devices deployed. The final detailed device locations will be developed based on further site investigation works conducted post-consent to determine detailed construction constraints. These details will be communicated to the Welsh Government and NRW pre-deployment via a process of site management connected to the discharge of consent conditions.

108. Seabed mounted devices may have a spacing of 50 to 100 m between centres of devices perpendicular to the flow and 100 to 250 m parallel to the flow. Such spacings may need to be modified to allow for seabed conditions, and this could alter spacings considerably, resulting in larger spacings.

109. The maximum case in terms of spacing would be floating tidal devices sharing moorings. Such devices may require up to 150 m between structure centres perpendicular to the flow and 250 m parallel to the flow.

110. Each device could move by up to 80 m (±40 m) in the direction parallel to the flow and 60 m (±30 m) in the direction perpendicular to the flow.

4.3.4.3. Potential Array Surface Area

111. A potential maximum surface area taken up by arrays for the Project has been calculated. The maximum surface area includes the space occupied by tidal devices (including TEC, supporting structures and foundations or anchors), as well as separation spaces between tidal devices. In other words, the surface area of a tidal device or array of tidal devices is greater than the seabed footprint as it includes the full area occupied by the tidal device(s) plus appropriate separation spaces between tidal devices. Surface area values for potential arrays have been derived via

Computer Aided Drawings (CAD) of layout parameters for a series of 30 MW arrays, combined to achieve a full 240 MW deployment scenario.

112. In order to identify a worst case for potential surface area for a deployment to 240 MW, the surface area associated with 30 MW arrays of a range of tidal device technologies were compared via CAD. The surface areas of the eight arrays thus identified were then summed to derive a maximum potential surface area for a 240 MW deployment. The value derived in this manner is 12,459,500 m^2 (12.5 km^2) for a full 240 MW capacity project – see **Table 4-8**.

Table 4-8 Assumptions used for worst-case surface area

Array No.	Device Category	Device Type	Max. Surface Area
1	Fully submerged seabed mounted device	QED Naval	1,838,600 m^2
2		Nova	1,241,800 m^2
3	Buoyant mid water device	SME PLAT-O	2,159,800 m^2
4	Surface emergent device	Magallanes	1,155,100 m^2
5		Orbital	1,155,100 m2
6		Aquantis	1,773,200 m2
7		Instream	2,070,400 m2
8		Tocardo UFS	1,065,500 m2
TOTAL			**12,459,500 m^2**

113. **Table 4-9** outlines the likely worst-case spacing and device areas based on indicative layouts. These parameters are therefore within the PDE of this EIA.

Table 4-9 Worst-Case Spacing Parameters for Devices within the MDZ

Device Category	Spacing between tidal device centres		Maximum extent of surface movement	
	Perpendicular to flow	Parallel to flow	Perpendicular to flow	Parallel to flow
Fully submerged seabed mounted device	50 to 100 m	100 to 250 m	NA	NA
Surface emergent and buoyant mid water device	50 to 200 m	120 to 500 m	60 (±30 m)	80 (±40 m)

4.3.4.4. Indicative Layout for Assessment

4.3.4.4.1. Indicative Layout for SLVIA and Shipping and Navigation

114. The worst-case parameters presented so far within this Chapter will be sufficient to inform the majority of the assessments undertaken during the EIA. For most receptors, deployment scenarios will remain within the levels of worst-case scenarios identified and no further definition is required.

115. However, for receptors such as shipping and navigation (**Chapter 15, Shipping and Navigation**), and Seascape and Landscape Visual Impact Assessment (SLVIA) (**Chapter 24, Seascape and Landscape Visual Impact Assessment**), the assessments undertaken require consideration of the location of arrays within the MDZ. For this purpose, an indicative layout, taking account of consultation with regulators and consultees has been derived.

116. **Figure 4-2 (Volume II)** shows an indicative surface emergent only layout taking into account the following considerations:

- Intention to manage the deployment of visually prominent devices as detailed in **Section 4.2.6** and summarised as:
  - Deployment of visually prominent devices focused on subzones 4 to 8;
  - Future deployment in subzones 1 to 3 under review on a case by case basis with regulators;
- Measures to manage shipping and navigation issues, summarised as:
  - Preference for the deployment of seabed mounted or buoyant mid water tidal devices in subzones 1 to 3, to maintain under keel clearance appropriate to vessels using those parts of the MDZ;
  - Maintenance of an area inshore of surface emergent arrays deployed in the MDZ of a minimum width of 1 km from shore and with a minimum UKC of 8 m;

117. The technologies used for illustration in the indicative array scenario assessed for SLVIA include up to 130 visually prominent surface emergent devices within subzones 4 to 8, as follows:

- 60 MW of large dual TEC tidal devices (30 devices);
- 30 MW of large spar buoy single TEC tidal devices (30 devices);
- 10 MW of multiple vertical axis TEC tidal devices (50 devices) and
- 30 MW of multiple TEC tidal devices (20 devices).

118. Under this indicative scenario, non-visually prominent surface emergent devices, seabed mounted devices or buoyant midwater devices would be deployed in other zones (1 to 3), subject to the requirements of other constraints, such as navigation.

4.3.4.4.2. Indicative Layout for Marine Mammals and Ornithology Assessments

119. In order to illustrate a potential full deployment to 240 MW and inform the assessment of potential impacts on seabirds and marine mammals (**Chapter 11, Marine Ornithology** and **Chapter 12, Marine Mammals**), the indicative surface emergent tidal device layout shown in **Figure 4-2** (**Volume II**) was used as the starting point for an indicative full deployment to 240 MW.

120. The indicative array of surface emergent outlined in **Figure 4-2** (**Volume II**), shows an indicative deployment of surface emergent tidal devices to 130 MW, with potential sub surface deployments not shown. **Figure 4-3** (**Volume II**) and **Figure 4-4** (**Volume II**) show the surface emergent indicative layout used to inform the SLVIA (**Figure 4-2, Volume II**) with the addition of a further 110 MW of non-surface emergent tidal devices, including seabed mounted and buoyant mid water devices. Two potential indicative layouts are shown, illustrated with the following technologies deployed in each:

- 35 MW of buoyant mid-water platform multiple TEC tidal devices (23 devices);
- 15 MW of small seabed mounted single TEC tidal devices (50 devices);

- 30 MW of seabed mounted multiple TEC tidal devices (25 devices); and
- 30 MW of large seabed mounted single TEC tidal devices (30 devices).

4.3.5. Offshore Electrical Infrastructure and Cabling

4.3.5.1. Export Cables

121. Up to nine export cables will be installed between the MDZ and the landfall. These subsea export cables are required to connect the tidal devices/arrays to the Landfall Substation, where the power is subsequently exported to the local distribution network via the Grid Connection Substation. The export cable corridor is shown in **Figure 1-1** (**Volume II**).

122. The size of the cables will be dependent on a number of factors. The required conductor size will be primarily determined by the necessary current carrying capacity which is influenced by transmission voltage, installation conditions (e.g. buried, in a duct etc), ambient temperature, phase spacing and arrangement, as well as the proximity of other cables.

123. Medium Voltage (MV) subsea power cables of the type used for offshore projects are generally built up with three single-cores (three phases), with a cross-section of between 50 to 500 mm^2, surrounded by filling material and covered by armouring, in addition to Low Voltage (LV) cables and multiple optical fibre elements for control and communications.

124. Cable armour is typically made of one layer of round 5 to 6 mm thick steel wire armour. Alternatively, flat strands may be used though these may not offer as much force protection. Where cable protection is a particular concern or where the integrity of the cable under pulling stresses is a concern, a second layer or more of armour may be added.

125. Burial will be difficult, or impossible, to achieve across much of the MDZ and the export cable corridor. An armoured cable will provide additional protection where suitable burial and protection cannot be achieved by other means or risk is perceived to be present. Due to the hard and rocky nature of the seabed, it is expected that the majority of the cables will be free laid with strategic protection (rock bags, concrete mattresses or split-pipe) at locations along the length. The main purpose of this cable protection will be to secure the cable to the seabed sufficiently to manage movement, without the need to protect all laid cable.

126. Armour will delay the onset of faults due to abrasion and less serious impacts, as well as increasing cable strength against pulling forces. This will improve cable survivability where it is exposed to mobile seabed material, currents and wave action, and, where it is potentially exposed (or part exposed) to bottom fishing activity. Armour will also assist with protection from anchor damage; however, heavy strikes will still likely result in failures.

127. The key parameters of the export cables are shown in **Table 4-10**. These parameters are therefore within the PDE of this EIA.

Table 4-10 Key Parameters of the Export Cables

Parameter	Value
Export cable diameter	Up to 120 mm
Cable diameter with split pipe cable protection	Up to 170 mm

Parameter	Value
Individual cable route lengths from each subzone	Between 1.2 and 6 km
Individual rock bags or concrete mattresses	Up to 270 (with a seabed footprint of up to 18 m^2 each) = 4,860 m^2
Total seabed footprint (nine cables plus cable protection systems and rock bags/mattresses)	11,745 m^2 [9]

128. More detailed cable route investigations will be required pre-installation (post-consent) to identify exact routes to shore. These studies will take account of the following criteria:

- Minimum spacing requirements to avoid derating of the cables and to ease laying operations and subsequent access;
- Avoiding key ecological (reef) features to minimise impacts on the seabed ecology and reduce physical risks to the export cable, in particular:
  - Avoid or minimise crossing of slopes beyond 10° which pose risks of cable movement and damage when surface laid
  - Avoid crossing scarps, ridges, scour lines or other areas where there are rapid variations in bathymetry which could lead to damage of the cables if laid across such a feature
  - Using appropriate cable protection to avoid cable moving around on the seabed; and
- Following a direction which runs parallel to the flood and ebb tidal current flows to maximise lateral stability of the cable on the seafloor.

129. Seabed morphology data collected via a project-specific geophysical survey during summer 2018 (Partrac, 2018) identified a significant sandwave feature, an estimated 27,258 m^2, located in the northern half of the MDZ and export cable corridor. Cables will be installed over this feature, potentially with jet trenching, and an as-laid survey will be undertaken to identify any areas where the cable is in suspension, followed by targeted remedial work at that time. If remedial work is required, the sand wave could be reduced using a mass flow excavator or dredger.

130. There is limited sediment in the nearshore sections within ‘Abraham’s Bosom’ where burial may be feasible via jet trenching. Feasibility will be confirmed by pre-installation geotechnical site investigations informing detailed design, however, sediment depth is limited and surface laying of cable, with cable protection is expected.

---

[9] Export cable length: 40.5 km: Diameter of split pipe: 170 mm: Area (40,500 m x 0.17 m = 6,885 m^2
Number of rock bags: 120: Footprint area of rock bags: 18 m^2 (4.8 m diameter): Area of all rock bags 270 x 18 m^2 = 4,860 m^2
Total seabed footprint export cable + protection (6,885+4,860) = 11,745 m^2

4.3.5.2. Inter-Array Cables

131. Inter-array cables will be laid between tidal devices; an electrical hub may be used or multiple devices may be connected in a ‘daisy-chain’ format. Tenants would be expected to install their own inter-array cabling where more than one device is being deployed within a subzone, and to connect their project to the export cable at its termination point.

132. The total length of inter-array cabling would be dependent on the array layout within each of the berths, dictated by geotechnical and bathymetric considerations (among others). The final length and layout of inter-array cabling will be determined by tenants prior to installation of their respective devices. The maximum inter-array cable length for the site is based on the maximum number of berths (eight). As per the export cables, for certain parts of the site, additional cable protection may be required to secure the cable to seabed at strategic points and prevent movement.

133. The key parameters of the array cables are shown in **Table 4-11**. These parameters are therefore within the PDE of this EIA.

Table 4-11 Key Parameters of the Array Cables

Parameter	Value
Number of individual cables (full 240 MW capacity)	Up to 740
Cable length	Up to 2.5 km per cable (majority will be less than 1 km)
Total length of array cables	Up to 204.5 km
Total seabed footprint (up to 204.5 km of array cables plus protection, plus rock bags on max 100m intervals)	30,040 m^2.

4.3.5.3. Offshore Cable Tails

134. Up to nine export cables connecting the landfall substation to the offshore arrays will be installed. These may be installed as follows:

- As a continuous export cable from landfall substation; or
- As a cable tail installed from the landfall substation each up to 620 m long to a location several hundred metres offshore. Each ‘tail’ would be terminated in the near shore of the export cable corridor, shortly after the ‘break out’ of planned HDD. As arrays are deployed, they would then connect through an export cable to the cable tail via a junction box or joint.

135. If HDD is not feasible, the proposed alternative method is to trench across the foreshore region. An excavator will create up to nine separate shallow trenches between 480 m to 740 m long (or installed within a single trench if possible) between the landfall and the transition pits, including the intertidal. If trenching is not possible, then cables will be surface laid and secured using concrete mattress and or rock bags. Quantities of rock bags or concrete mattresses for the export cable route, including the intertidal area, are included in Table 4-10. It is anticipated that at least double armoured cables of up to 300 mm^2 cross section may be used; resulting in a diameter of 120 mm.

4.3.5.4. Hubs

136. Hubs would typically connect and aggregate power from a number of individual devices. Hubs may be 'passive', with a busbar joining multiple tidal devices together; or 'active', containing a transformer, switchgear and possible control equipment (convertors).

137. Seabed mounted hubs are likely to be largely cylindrical structures, between 2 and 6 m in diameter, up to 10 m long. They may also have 'external' sealed transformers that would fit into a similar footprint. Height of the structure off the seabed is likely to be approximately 5 to 8 m. Keel clearance will depend on the water depth and the type of hub, with a minimum of 20 m UKC at all locations with seabed mounted hubs.

138. Some hubs may be on a surface emergent structure; a small jacket or monopile structure (2 to 6 m diameter monopile, up to 18 m above the sea surface at LAT). The electrical equipment will be within a larger diameter pile.

139. It is estimated up to 120 separate electrical hubs may be required to aggregate output from multiple devices. The following scenarios are anticipated:

- Up to 120 seabed mounted hubs, fully submerged; or
- Up to 93 floating surface emergent hubs; or
- Up to eight seabed mounted, surface emergent hubs.

4.3.5.5. Summary of Cabling Offshore and Electrical Infrastructure Parameters

140. The worst-case scenario for the cabling and electrical infrastructure to be used in the impact assessment, is presented in **Table 4-12**.

Table 4-12 Worst-case Scenario for Cabling and Electrical Infrastructure

Parameter	Value
Export Cables	
Number of export cables (including cable tails, if required)	9
Total length of export cables	40.5 km
Maximum length of individual export cables	6 km
Minimum length of individual export cables	1.2 km
Footprint of export cables and split-pipe protection	6,885 m^2 (4,860 m^2 cable + 2,205 m^2 split-pipe protection)
Footprint of additional cable protection (rock bags)	4,860 m^2
Footprint of export cables, split-pipe protection and rock bags	**11,745 m^2**
Inter-Array Cables	
Number of inter-array cables	740
Total length of inter-array cables	204.5 km
Maximum length of individual array cable	2.5 km
Footprint of inter-array cables, split-pipe protection and rock bags	**30,040 m^2**

4.3.6. Navigation and Monitoring Equipment

141. The MDZ will be marked by navigation buoys. The exact location, number and nature of the marking and navigation buoys will be determined through consultation with Trinity House (TH), the Maritime and Coastguard Agency (MCA) and navigation stakeholders. Buoys will be provided in accordance with International Association of Lighthouse Authorities (IALA) standards.

142. As a minimum, the northerly, easterly, southerly and westerly boundaries of the MDZ will need to be marked with the appropriate IALA cardinal mark. There may be additional cardinal markers or special mark buoys required, particularly along the northern and southern boundaries of each array. The exact requirements for marking will be confirmed by appropriate regulators and applied via consent condition and their discharge.

143. Cardinal buoys will be required to have flashing white lights with a visibility of not less than 5 nautical miles (nm). Special Mark buoys to have flashing yellow lights with a visibility of not less than 5 nm. Buoys may be required to have automatic acoustic signals that are triggered in low visibility.

144. Substantial yellow colouring is the worst-case in terms of the appearance of any surface-emergent elements of the PDE, in compliance with IALA guideline O-139 Section 2.4.1 2F. Tidal devices will be lit at night in conformance with guidance from TH and IALA. Fully submerged devices and electrical hubs may have a marker buoy to assist with access, communications and retrieval.

145. There may be a requirement for some floating and seabed mounted environmental monitoring platforms to be deployed throughout the MDZ.

146. A number of Acoustic Doppler Current Profilers (ADCPs) will also be deployed across the site to measure current flow speeds and directions. Each ADCP is expected to be a seabed mounted unit, deployed in a stainless-steel seabed frame.

147. The layout options considered may include combinations of surface emergent and fully submerged devices. As such appropriate consideration will be required to ensure that the method and type of marking are appropriate for the device type and infrastructure.

148. The key parameters of the navigation and monitoring equipment are shown in **Table 4-13.** These parameters are therefore within the PDE of this EIA.

Table 4-13 Worst-case Scenario for Navigation and Monitoring Equipment

Parameter	Value
Number of navigation buoys	Four
Dimensions of navigation buoys	Up to 3 m, with a focal plane height (position of light) of 6 m
Number of marker buoys	Each fully submerged seabed mounted or mid-water buoyant device
Dimensions of marker buoys	Up to 1.2 m, with a focal plane height of 1.5 m
Number of environmental monitoring buoys	Five

Parameter	Value
Dimensions of environmental monitoring platforms	Up to 3.6 m above sea level
Number of ADCPs	Up to 40
Diameter of ADCP	Approximately 1.5 m
Footprint of individual ADCP (and total across MDZ)	7 m^2 (378m^2)
Number of IALA cardinal marks	Four
Dimensions of IALA cardinal marks	Up to 3 m, with a focal plane height of 6 m
Seabed footprint of anchors	Concrete weight up to 2 m in diameter, with a chain catenary in contact with the seabed of up to 30 m
Visibility of fully emergent/floating devices	Coloured yellow above water and with navigation lights

4.4. ONSHORE INFRASTRUCTURE

149. The boundary for the ODA is provided in **Figure 1-2** (**Volume II**). The Landfall Substation is within land currently farmed by Ty-Mawr farm, in the area of Holy Island known as Penrhos Feilw. From the Landfall Substation location, the majority of the onshore cable route follows the minor road network to towards the A55 and Holyhead to Bangor rail line.

150. The cable will be routed via trenching to the Switchgear Building and be subsequently routed via trenching, with a trenchless crossing under the A55 and rail line, to the Grid Connection Substation.

151. The key components of the onshore works associated with the Project are detailed in this Section, in the following order:

- Cable landfall;
- Landfall Substation;
- Onshore cable corridor;
- Switchgear Building; and
- Grid Connection Substation.

4.4.1. Cable Landfall

152. Landfall will be located within the bay on the western coast of Holy Island known as Abraham's Bosom. There are two main methods which could be used for cable installation at landfall:

- HDD; or
- Open cut trenching.

153. HDD is the preferred method to achieve landfall. If HDD is not feasible, the proposed alternative method is to trench across the foreshore region. An excavator will create up to nine separate shallow trenches between 480 m to 740 m long (or installed within a single trench if possible) between landfall and transition pits. This will be followed by installation and pinning of ducting and/or subsea cable within the trench across the cliff top and fore shore, with a split-pipe used to carry cabling down the cliff face. If trenching is not possible in the foreshore, then cables will be surface laid and secured using concrete mattress and or rock bags. Quantities of rock bags

or concrete mattresses for the export cable route, including the intertidal area, are included in **Table 4-10**.

4.4.1.1. HDD Compound and Transition Pits

154. As noted earlier, HDD is the preferred method of cable installation. The proposed route to the HDD exit point measures approximately 0.55 km in length, from Abrahams Bosom in the north, passing under South Stack Road, beneath a campsite and into Ty-Mawr farm field. The route and other works will be accessed by a temporary track.

155. The transition pit and HDD drilling rig compound will be located in Ty-Mawr farm field, immediately south-west of the existing farm buildings. There will be one transition pit, up to 15 m x 85 m x 1.5 m deep, equating to a footprint of 1,275 m^2, excavated volume 1,912.5 m^3 in addition to trenching excavation or HDD cutting volumes. All transition pits will be buried upon completion of the works and covered by a depth of approximately 200 mm topsoil (recovered from excavated materials) and seeded with grass mix. The final volume is subject to confirmation of geology and drill geometry.

156. Material excavated will be re-used on site if possible. If it cannot be re-used it will be removed from site for appropriate re-use elsewhere.

157. Within the transition pit, each of the nine submarine cables may be jointed and transitioned to 9 sets of separate onshore cables. Each of the 9 sets of onshore cables will then require between 2 and 8 ducts depending on the specific requirements of the tidal energy devices. The maximum case of 8 ducts comprise, 3 x HV, 1 x fibre optic, 1 x LV and a spare, 1 x Extra Low Voltage and a spare. The minimum case of 2 comprise a single, multi-core HV cable and a fibre optic. This gives a maximum case of 72 ducts and a minimum case of 18 ducts.

158. The cable route from transition pit to the Landfall Substation may be up to 0.4 km in length and will be trenched. Up to nine draw pits may be required within that route to allow for changes in direction of the trench. Each draw pit will be approximately 2 m x 2 m x 1.5 m deep, subject to final detailed design.

159. A precast concrete box culvert will be installed beneath the Ty-Mawr Access Road to allow the onshore cable ducts to pass through to the Landfall Substation whilst minimising disruption to the existing access.

160. Within the HDD compound, plant (i.e. generator, drilling rig) will be present to support HDD operations. The HDD compound will be bounded by a 3.5 m high acoustic demountable fence located around the equipment and a 2 m high solid hoarding fence built around the compound boundary.

4.4.1.2. Landfall Trench/Surface Laying Option

161. As discussed above, should HDD not be feasible, an alternative approach would be open cut trenching. This would involve cutting shallow trenches across the beach and pinning and/or ducting the subsea cable, within a split-pipe to the cliff face. Should trenching not be possible, then cables will be surface laid, with cables crossing the intertidal area requiring protection using

rock bags or concrete mattresses. From the cliff top, cables will be buried in trenches that cross the fields and South Stack Road to the transition pits and onwards to the landfall substation.

162. Up to nine shallow trenches (slots within the cliff face) would be created using a rock cutter and then the cables would be 'surface laid' over the cliff using a split pipe or J-tube. A J-tube type solution is essentially very similar to the split pipe, or duct approach. In this way, cable ducts will be fixed to the cliff face. The J tubes would extend above the top of the cliffs and then the cables would emerge before being buried across the fields to the transition pits. As much as possible the pipes would be marshalled to a common location and brought down the cliff in as small an area as possible. Up to 500 mm separation between J-tube centres is proposed. The total width of grouped J-tubes would be up to 30 m.

163. Depending on the geology of the foreshore, an individual trench width up to 600 mm, or a single trench with all nine cables laid within it of up to 10 m width and 0.5 to 1.2 m deep will be constructed using open cut trenching. Alternatively, split pipes could also be used in the foreshore region, and the cables surface laid and protected, should trenching not be feasible.

164. A temporary working corridor width of 30 m is assumed for the foreshore and cliff works.

4.4.1.3. Temporary Works

165. It is expected that up to one temporary access track to the transition pit or to a temporary construction compound will be required during the construction phase.

166. To create the temporary works areas and access track, it is anticipated that 0.15 m of topsoil will be stripped back, stockpiled and protected during storage whilst the construction works progress. This will be reinstated, so there will be no waste topsoil arising from this activity. It has been assumed that 0.3 m of hardstanding (permeable gravel aggregate underlain by geotextile) will be placed over each area during construction. A layer of tarmac may also be placed over the temporary works areas that will use/store heavy machinery/equipment. Any surface vegetation removed as part of excavation works will be separately stockpiled and sent for recovery at a composting or an anaerobic digestion facility.

4.4.1.4. Summary of Landfall Installation Parameters

167. The requirements for installation of the landfall by HDD and trenching are presented in **Table 4-14.**

Table 4-14 Construction Parameters for Installation of the Landfall by HDD and Trenching Methods

HDD Installation (preferred)	Trenching (worst-case)
Up to nine cable tails.	Up to nine cable tails.
Up to nine separate drills; each up to 550 m long, nominally 450 mm diameter.	Up to nine separate shallow trenches (slots within the cliff face).
Separation of 10 m between HDD entry points.	Trenches between 480 m and 740 m long from transition pit to intertidal.
Separation of 20 m between HDD exit points.	Individual trench widths of up to 600 mm. Or a single trench with all nine cables laid within it of approximately 10 m width and 0.5 to 1.2 m deep.

HDD Installation (preferred)	Trenching (worst-case)
Total drill cuttings volume could be up to 900 m^3 (total amount for all nine drills).	Duct or split pipe over 370 to 550 m of each cable, up to 350 mm external diameter.
Trenching works from transition pit to Landfall Substation.	Up to 500 mm separation between J-tube centres.
Transition pit up to 15 m x 85 m x 1.5 m deep, equating to a footprint of 1,275 m^2, excavated volume 1,912.5 m^3.	Total width of grouped J-tubes would be up to 30 m.
Up to 9 draw pits of 2 m x 2 m x 1.5 m deep equating to a footprint of 36 m^2, excavated volume 54 m^3.	Total material removed from site could be approximately 8,880 m^3 [10]; with the majority of material replaced to backfill the trench after the ducts / cables were installed. Worst case assumption all material removed in onshore or offshore dependent on receptor.
HDD compound will be bounded by a 3.5 m high acoustic demountable fence located around the equipment and a 2 m high solid hoarding fence.	Cables crossing the intertidal area may also require protection using rock bags or concrete mattresses or equivalent methods.
Temporary works area up to 120 m by 70 m (total area for HDD rig, site office and equipment plus laydown area).	Temporary works area up to 100 m by 50 m (for site office and equipment plus laydown area). A temporary working corridor width of 30 m.
From transition pit to Landfall Substation, each of the 9 onshore cables will require between 2 and 8 ducts depending on the specific requirements of the tidal energy devices. The maximum case of 8 ducts comprise, 3 x HV, 1 x fibre optic, 1 x LV and a spare, 1 x Extra Low Voltage and a spare. The minimum case of 2 comprise a single, multi-core HV cable and a fibre optic. This gives a maximum case of 72 ducts and a minimum case of 18 ducts.	From transition pit to Landfall Substation, each of the 9 onshore cables will require between 2 and 8 ducts depending on the specific requirements of the tidal energy devices. The maximum case of 8 ducts comprise, 3 x HV, 1 x fibre optic, 1 x LV and a spare, 1 x Extra Low Voltage and a spare. The minimum case of 2 comprise a single, multi-core HV cable and a fibre optic. This gives a maximum case of 72 ducts and a minimum case of 18 ducts.

168. There are currently two HDD scenarios to installing the export and onshore cables that may be possible:

- **Scenario 1:** HDD boreholes, onshore cable ducts and infrastructure are installed and subsequently pull through export and onshore cables. This work would take place during the construction phase.
- **Scenario 2:** HDD boreholes, onshore cable ducts and infrastructure are installed during the construction phase. Each developer will pull through their export and onshore cables and therefore these operations will be staggered during the service life of the facility.

169. Scenario 1 represents the worst-case scenario for cumulative noise, visual and disturbance impacts and therefore is assessed as such within the relevant ES chapters.

4.4.2. Landfall Substation

170. The landfall substation will house the connection between the offshore export cables and the onshore cable to the grid connection substation. The landfall substation will be positioned within

[10] Based on calculation of trenches of 740 m length, 10 m width and 1.2 m depth

a single field adjacent to South Stack Road to the west of Tŷ-Mawr Farm. It will comprise three separate buildings of differing footprints, all up to approximately 7 m high. There would also be a separate transformer compound and external working areas and parking. The layout also comprises a facility for electric vehicle charging.

171. The site comprises a fenced compound approximately 80 m by 80 m and contains three buildings: the first 62 m by 22.5 m by 7 m high (or equivalent area); second to 28 m by 10 m by 7 m high (or equivalent area) and the third to 8 m by 8 m by 7 m high. The third building is within a substation compound to 28 m by 36 m by 7 m high (or equivalent area). The estimated total footprint of the landfall substation compound is 6,400 m^2.

172. An indicative site layout for the Landfall Substation is provided in **Plate 4-7**, which may be subject to further refinement.

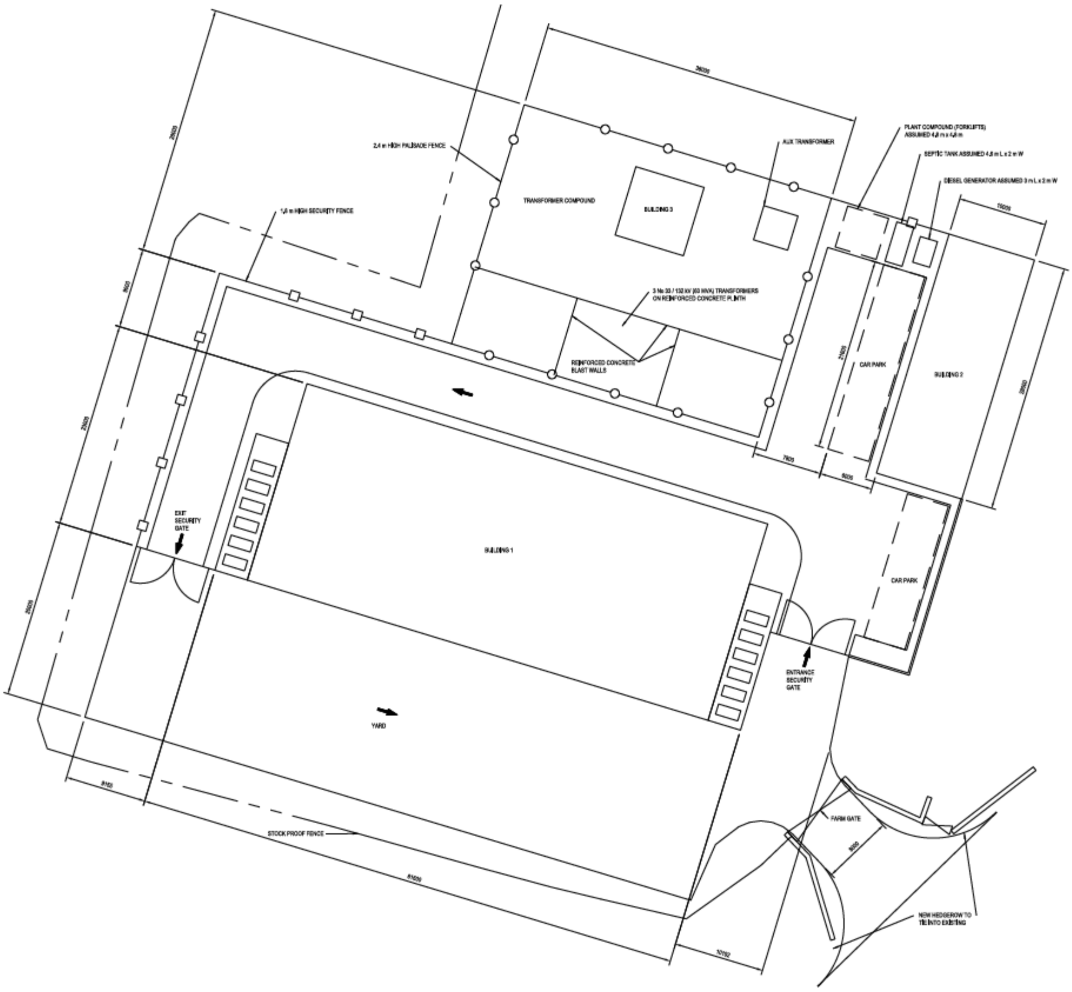

Plate 4-7 Indicative Site Layout – Landfall Substation

173. The main building will contain up to nine electrical plant rooms for developers to contain step-up transformers. The building will also support external (within a dedicated enclosure) Cooling/Ventilation systems. The buildings will be of a mainly steel portal frame construction with a pitched roof. The walls will be clad in preformed steel and, if necessary, timber batons. The walls of the flanking cooler compounds will be clad with ventilation louvres.

174. The landfall substation is positioned within a recessive location in the landscape, within a valley, and uses the landform to help integrate the substation into the landscape. The landfall substation will be cut into the valley side rather than building a platform out from the valley slope. There will be a retaining structure (to reduce the amount of cut) along the western and northern edges of this landfall substation site, assumed to be constructed of stone filled gabions, possibly combined with underlying rock. Approximately 13,900 m^3 will be cut in to the landscape and a fill of approximately 130 m^3.

175. There will be a temporary construction compound and laydown area with a footprint of 50 m by 100 m, or the equivalent area, located to the south west of the landfall substation.

176. Permanent access is proposed to the landfall substation location during construction and operation.

4.4.3. Onshore Cable Corridor

4.4.3.1. Onshore Corridor Overview

177. The onshore cable route will feature up to two 132 kV cable circuits. Each circuit would consist of three power cables plus a fibre optic cable. This results in up to six power cables and two fibre optic cables in total, each of up to 110 mm diameter cable for each circuit (up to six in total).

178. The onshore cable route will be of up to 8.1 km total route length, dependent on final detailed route design, with the cables trenched into the local road network so much as is practicable, given constraints in road width and services already within the road. It is assumed, based on Design Manual for Roads and Bridges (Highways Agency, 2019), that the profile of the trench comprises 0.3 m porous asphalt, 0.3 m base course and the remaining 1.1 m is road base. However, it is acknowledged that some more rural roads are less likely to have as comprehensive a make-up.

179. There are two trench types as shown in **Table 4-15**, one from the Landfall Substation to Switchgear Building and one from the Switchgear Building to the Grid Connection Substation.

Table 4-15 Cable Route Trench Parameters

Cable route parameter	Landfall Substation to Switchgear Building	Switchgear Building to Grid Connection Substation
Circuit	132 kV	33 kV
Trench depth	1620 mm	1620 mm
Trench width	1400 mm	2000 mm
Length	6675 m	1420 m
Joint bays (No.)	18	2
Joint bay chamber depth	1.65 m	1.65 m
Joint bay chamber width	2 m	3 m
Joint bay chamber length	12.5 m	5 m
Draw pits (to be fully reinstated following works) (No.)	35	7
Draw pit depth	1.65 m	1.65 m

Cable route parameter	Landfall Substation to Switchgear Building	Switchgear Building to Grid Connection Substation
Draw pit width	3 m	5 m
Draw pit length	8 m	8 m

180. Where road width is insufficient, the road verge and adjacent field areas may be utilised, within a maximum work corridor width of 30 m.

181. Approximately 20 m x 7 m of hardstanding will be required around each joint bay to provide enough space for the cable pulling works. This area may require use of field areas adjacent to the road.

182. A length of cable installation by HDD will be required to cross the railway line and A55 at the Grid End location. The transition pits will be located either side of the A55 and railway line and in line with the proposed Grid Connection Substation. The two transition pits (exit and entry pits) will be 80 m x 15 m x 1.5 m deep. The final location will be determined within detailed design.

4.4.4. Switchgear Building

183. The infrastructure at Parc Cybi will consist of a 33 kV switchboard room and metering room. The existing road will be used to access this location, during both construction and operation of the switch. The Switchgear Building would comprise a single building up to 9.4 m x 5 m, with a maximum height of 4 m. It would be positioned to the north east of the existing substation within the Parc Cybi employment site (as described in Isle of Anglesey Local Development Plan, 2017), separated from this existing infrastructure by part of the internal road layout. The footprint of the Switchgear Building is 38 m^2, with a temporary construction compound of up to 30 m x 20 m. An indicative site layout for the Switchgear Building is provided in **Plate 4-8**, which may be subject to further refinement.

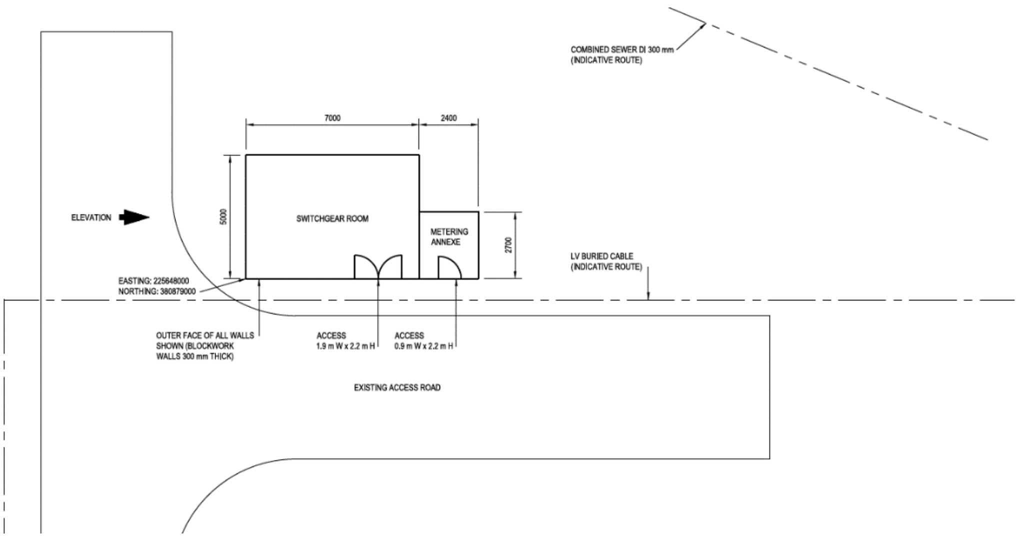

Plate 4-8 Indicative Site Layout – Switchgear Building

4.4.5. Grid Connection Substation

184. A substation will be required to achieve connection at the grid connection point. The Grid Connection Substation will be located within the land that forms part of the former Anglesey Aluminium works to the north east of Holy Island, south east of Holyhead, now known as Orthios. Connection to existing electricity network will be through existing infrastructure.

185. The existing road to the Orthios site will be used to access this location, during both construction and operation.

186. The Grid Connection Substation will contain up to seven energy storage systems each with two sets of inverters, HVAC units and transformers. There will be up to three substation buildings, (two 132 kV substations and one 33 kV) and one static synchronous compensator (STATCOM) building. The compound will also contain external air-cooled reactors and cooling units.

187. The Grid Connection Substation will have an overall footprint of up to 104 m x 62 m. It would contain external plant and equipment, together with four buildings. The maximum height of the proposed structures within the Grid Connection Substation will be 9 m. An indicative site layout for the Grid Connection Substation is provided in **Plate 4-9**, which may be subject to further refinement. An indicative location for the Grid Connection Substation is shown in **Figure 1-2** (**Volume II**) and throughout supporting figures to the technical chapters. However, note that this is indicatively only and will be refined upon detailed design.

188. A temporary construction compound and laydown area will also be created, up to 50 m x 100 m, or equivalent area.

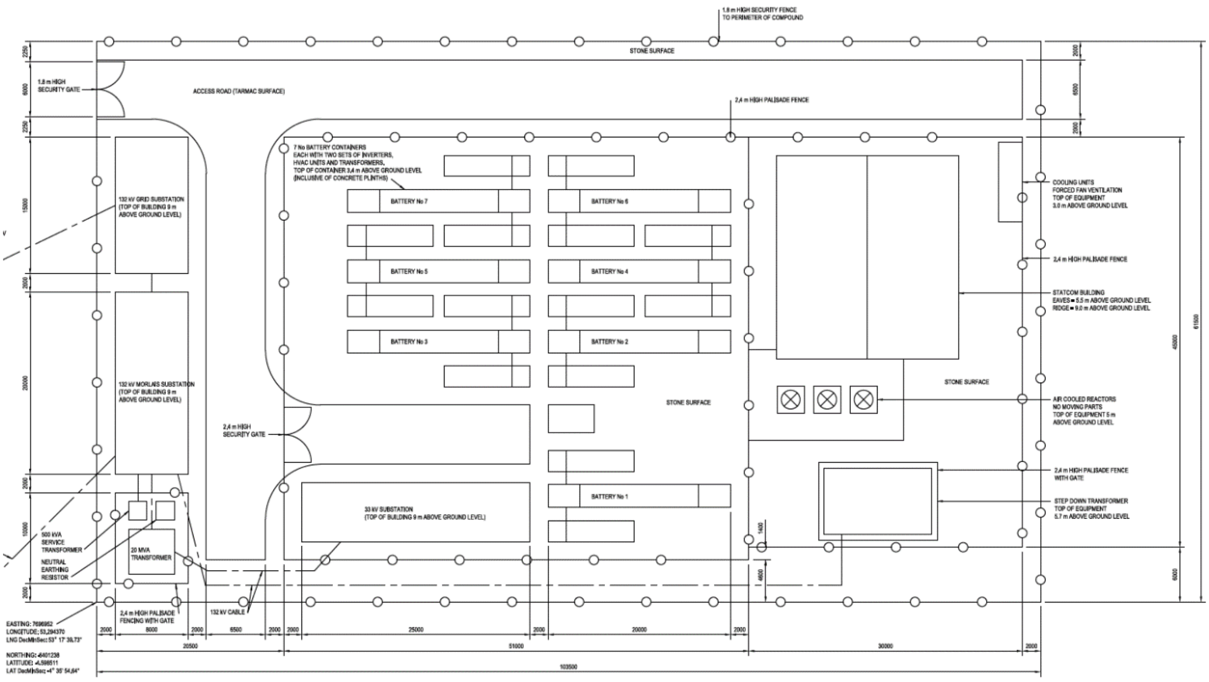

Plate 4-9 Indicative Site Layout – Grid Connection Substation

4.4.6. General Building Parameters

189. The parameters bulleted below are relevant to the infrastructure within the ODA, including the Landfall Substation, Switchgear Building and Grid Connection Substation:

- Appearance of the buildings;
- Lighting;
- Screening structures;
- Access;
- Foundations;
- Building materials; and
- Drainage.

4.4.6.1. Appearance

190. The preferred appearance of the Landfall Substation is for agricultural (shed-like) buildings (which will house indoor equipment), which will allow at least partial mitigation of noise and visual impacts of outdoor equipment. The buildings will be steel portal frame structures with pitched roofs and can be clad in timber or a profiled metal cladding. Differently, the Grid Connection Substation and Switchgear Building are located within the context of buildings that are comparable in form and function. It is anticipated that the proposed the buildings would be constructed using materials that are similar to those located in the immediate surroundings i.e. within the Orthios and Parc Cybi sites.

191. The buildings may feature low level ventilation louvers to bring in cooler outdoor air, and high-level exhaust cowls with ducted axial fans. These ventilation features would be visible from outside the building.

192. Distinct cooler compounds are to be steel structures with ventilation louver cladding to bring in cooler outdoor air. The cooler compounds are anticipated to abut with the buildings and will be visible from outside the building.

193. The perimeter will be protected by a weld steel fence. The design of the fence shall be such that it blends in with the local environment as far as possible. The perimeter fencing would be a minimum of 1.8 m tall.

194. Outdoor equipment may be placed outside in the external compound at the Landfall Substation and the Grid Connection Substation. Reinforced concrete blast walls will provide a protective barrier between adjacent transformers and enclosure whilst palisade fencing can be installed around the perimeter of the external compound to provide security. The palisade fencing will be installed hidden from view within the substation perimeter fence. The palisade fencing would be at minimum 2.4 m tall.

4.4.6.2. Lighting

195. A minimum of 110 lux (lx) directed lighting will be required around the entry to the Landfall Substation and Grid Connection Substation, which will be turned on when needed, and may be equipped with motion sensors. Adequate lighting will be provided for any outdoor electrical plant areas in the form of compound floodlighting to facilitate any inspection or maintenance of electrical equipment at night. This would normally provide 10 lx along access paths and around major items of electrical plant. This may require columns to fix lighting to although electrical

clearances will be followed to eliminate the possibility of a column falling across electrical equipment.

4.4.6.3. Access

196. Access and egress to each site will be on a 24 hour and seven days per week basis. It is anticipated that access will be via secure key pad and automatic gate.

197. Specific areas of the road network may need works to assist with turning radius or weight distribution for transport of low loader vehicles.

4.4.6.4. Foundations

198. Each item of outdoor and indoor electrical and non-electrical equipment will have a concrete slab foundation. Strip and pad foundations will be utilised if possible.

199. It may be necessary to utilise a piled foundation solution, using pre-cast concrete piles or similar, if warranted, depending on the underlying geological conditions (to be determined by the civils contractor) and the outcome of post-consent, pre-construction archaeological evaluations. The transformer foundations will be bunded to contain any risk of oil leakage from the transformer or any other oil-filled plant.

4.4.6.5. Building Materials

200. The interior of the Landfall Substation building, an agricultural shed type structure, will have fire barrier walls made of dry wall cladding. The main transformer room for the agricultural shed will have firewalls constructed out of concrete or concrete blocks. Other rooms may similarly utilise blockwork construction including the switchgear, battery and auxiliary power rooms.

201. It is anticipated that the proposed Grid Connection Substation and Switchgear Building would be constructed using materials that are similar to those located in the immediate surroundings i.e. within the Orthios and Parc Cybi sites.

4.4.6.6. Surfaces

202. Hard standing will be in the form of hard core or tarmac surfaces on the access roads within the Landfall Substation and the Grid Connection Substation. This pertains to the 5 m to 7 m wide perimeter access road, additional access areas around transformers and reactors, building entrances, and the main substation entrance and car park.

203. Footpaths or pavement in and out of the grid connection substation building and areas commonly accessed may be of poured concrete instead of hard core or tarmac.

204. Outdoor areas within the Landfall Substation and Grid Connection Substation compounds will have a layer of crushed rock or gravel approximately 80 mm to 150 mm thick. This will be everywhere inside of the substations' perimeters with the exception of the access roads, protruding equipment foundations, and buildings.

4.4.6.7. Drainage Systems

205. Generally, the aim will be to discharge surface water runoff as high up the following hierarchy of drainage options as reasonably practicable:

- Priority Level 1: Surface water runoff is collected for use;
- Priority Level 2: Surface water runoff is infiltrated to ground;
- Priority Level 3: Surface water runoff is discharged to a surface water body;
- Priority Level 4: Surface water runoff is discharged to a surface water sewer, highway drain or another drainage system; or
- Priority Level 5: Surface water runoff is discharged to a combined sewer.

206. Guidance indicates that Priority Level 1 is the preferred (highest priority) and 4 and 5 should only be used in exceptional circumstances.

207. A Surface Water Drainage Strategy will be developed according to the principles of the Sustainable Drainage Systems (SuDS) hierarchy and in line with S1 Surface water runoff destination, as set out in the Statutory Standards for sustainable drainage systems.

208. The foul drainage system is to take wastewater from personnel areas and connect into a local septic tank with an overflow into a local infiltration trench. The surface water system collects run off from buildings and roads run through oil interceptors and discharged using bund pumps, so all contaminants are removed from the water. The drainage system will be designed to handle the worst-case water situation and with consideration of flood risk. The surface water may connect into a sewer system, discharge into a local watercourse if possible, septic tank, or be discharged into a soakaway system constructed nearby.

209. An oil interceptor may be required to be installed to protect the surface water system from pollution. Such an interceptor capacity should be adequate to the area intercepted by the substation surface water drainage system.

4.5. CONSTRUCTION METHODOLOGY

4.5.1. Offshore

4.5.1.1. Device Installation

210. Due to the wide range of possible device types that may be installed within the MDZ, it is not possible to specify the exact installation methodology that will be adopted. The consultation process with potential developers has been used to inform the likely foundation and device installation methods that may be used at the site.

211. A number of installation method could be adopted, including those below:

- Installation of foundations and support structures, then lower, ballast or pull the TEC(s) down onto the foundation;
- Installation of foundation, support structures and TEC as a complete unit from a heavy lift (dynamic positioning or moored barge) or bespoke vessel;

- Installation of foundation, support structures and TEC as a complete unit towed to site and then ballasted into position (seabed or mid water column); and
- Floating and mid water buoyant systems will be towed to site and while on the surface attached to pre-installed anchors and mooring lines / cables. Mid water buoyant devices will then be winched below the surface via mooring / anchor lines.

212. Piled foundations would mainly be installed by a moored barge or Dynamic Positioning (DP) vessel with sufficient cranage (250 t to 400 t). Monopile and pin-piles will be installed through remote drilling using a subsea rig controlled from a DP vessel (up to three days per large pile drilled, or 1.5 days for pin-piles).

213. TECs and supporting structures would then be installed separately using a DP vessel (potentially the same as for the foundation installation) or a multicat vessel.

214. A moored barge may be suitable for some installations. Such a barge would be approximately 100 m x 30 m and have four to eight 100 tonne gravity blocks (5 m by 5 m) or drag anchors (3 m x 5 m) with some anchor chain catenary, estimated at 400 m to 500 m length on seabed and 1 m diameter. A typical mooring spread would consist of moorings on a 'radius' from the vessel centre of between 500 m and 800 m. Overall 'footprint' of mooring spread would be a rectangle of approximately 500 m to 1,400 m x 850 m to 1,600 m. This type of vessel will require one or two small support vessels (30 m x 22 m) to assist with positioning and anchor deployment.

215. A DP vessel would be of a similar size to the barge (155 m x 30 m) but would not disturb the seabed and may not require any tugs.

4.5.1.2. Cable Installation

216. After HDD drilling, diver operations will be required to fit a seal/cap to the offshore end of each of the ducts. This would be carried out by a small dive support vessel/multicat and will take approximately five days to complete.

217. Before export cable laying, diver operations will again be required to open the ducts and install pick-up lines for the cable laying vessel. If the HDD end is in an area of sediment, it may need to be exposed which will require diver excavation. This would also be carried out by a small dive support vessel/multicat and take approximately five days.

218. Export cables will be installed using specialist cable installation vessel, barge or multi-cat. Where a cable tail is used, the vessel will pick-up the cable ends, connect the cables, and lay towards the tidal array. Where cable tail is not used, then the cable will be continuous from HDD to the array. Connection to device arrays could include daisy-chained devices as well as connection via single and multiple hubs (submerged and surface emergent).

219. Post cable installation, if the HDD is to be bentonite filled then the offshore end will need to be vented which will require further diver operations. This would also be carried out by a small dive support vessel / multicat and take approximately five days.

220. Following surface cable laying, cable protection systems, either concrete mattress or rock bags will be installed. Sediment within the MDZ is limited, however, burial of the cable in the first

1 km to 2 km may be attempted with multiple passes of a jet trenching Remotely Operated Vehicle (ROV), or possibly diver burial techniques over shorter lengths in the shallow water.

221. Installation of export and array cables could require a medium sized cable installation vessel (up to 140 m long and 6 m draft), plus barge (could be up to 130 m long x 30 m wide) for installation of rock bags / mattresses (30 m long x 12 m wide), with a small additional support vessel for each.

222. It is anticipated that there will be a safety zone of 500 m around all installation vessels.

223. The cable vessels will be mobilised directly from the manufacturing / supply port; likely to be Hartlepool, Norway, Italy or Germany for cables. Installation support ports are likely to be Holyhead, Mostyn, Liverpool or Birkenhead; although ports further afield may be used by some developers.

4.5.1.3. Cable Tail Installation

224. If cable tails are installed this will be undertaken by a cable vessel, barge or multicat (up to 140 m long and 6 m draft), plus small support vessel(s). The cable installation vessel is likely to be on site up to ten days; cable protection installation vessels may be on site for up to two days.

4.5.2. Onshore

4.5.2.1. Onshore Cable Route

225. Trenching for the onshore cables will be undertaken using a large excavator to dig up the ground along the route. Rock breakers will also be required along some sections.

226. Where the route goes through fields the trench will be backfilled with sand and/or stabilised material to a depth of approximately 150 mm above the top of the cables. The material originally removed from the trench will be replaced on top of the stabilised material. Finally, the trench will be topped up with a minimum of 150 mm of topsoil and the land restored as close as possible to its original condition. The cable will be buried to a depth of approximately 1 m, from the surface to the top of the ducts. Up to 30 m working width will be required for plant access, lay down of equipment, top soil, spoil and trench shoring along the cable route.

227. Cable installation within a road or a verge will follow the methodology of cable installation in a field. However, due to the restricted environment, installation activities will need to be sequenced and material will need to be removed from the site or kept off site until required. A trench will be cut through the road surface and excavated. Once the trench is prepared, the cables or ducts will be laid, and the road reinstated. A working area of approximately 6m width would suffice for installation in a single lane road.

228. The onshore cables will cross the A55 and the railway line within an area opposite the Grid Connection Substation. The HDD rig will either be positioned within the footprint of the Grid Connection Substation or on the opposite side of the A55/railway. The route will be perpendicular to the A55 but the exact location of the entry/exit pits will be refined during detailed design. Up to two crossings, each involving six drills, will be required with a drill length of

approximately 150 m. Two site areas will be prepared for each HDD crossing; the drill rig site where the HDD enters the ground, and the exit point on the other side of the crossing.

229. When crossing underground services, it is likely that the cable trenches will pass underneath existing services, unless the service is extremely deep. This will be determined through further surveys.

4.6. CONSTRUCTION SCHEDULE

230. An overview of the indicative Project construction schedule is shown in **Table 4-16**. This is based on the assumption of project consent in March 2021 and on the preferred option of HDD construction methods at the landfall. Further detail on the offshore and onshore timescales are provided in **Section 4.6.1** and **Section 4.6.2**, respectively.

Table 4-16 Indicative Morlais Construction Programme

Task Name	Start	Finish
Grid Connection Substation		
Construction	January 2022	October 2022
Onshore Cable Route		
Transition Pit installation	September 2022	December 2022
HDD works mobilisation and preparation	November 2021	June 2022
Onshore Cable Construction	March 2022	April 2023
Landfall Substation and Switchgear Building		
Preparation works	November 2021	December 2021
Construction works	February 2022	October 2022
Electrical Installation	July 2022	December 2022
Cable Connection	November 2022	January 2023
Offshore Infrastructure		
Installation of infrastructure within the MDZ and ECC	January 2023	December 2023

4.6.1. Offshore

231. Offshore works (for installation of tidal devices and associated cabling and infrastructure) would be phased over a period of several years, taking up to 15 days per device or hub and up to 1.5 day for each inter-array cable, and up to 20 days for each export cable plus up to 12 days each for cable protection. For the main installation phase of tidal devices and associated electrical hub infrastructure, the typical time for complete installations is between three and 15 days per device, including foundation.

232. For the full 240 MW capacity scenario, the worst-case scenario in terms of installation period would involve all devices requiring pin-piled anchors requiring multiple drilling operations. These could take between 4 and 15 days per device. Therefore, total time on site installing developer devices (and hubs) could be up to 4,306 days.

233. For the export cable installation, it is anticipated that each of the nine export cables would take up to 20 days installation (total of 180 days). For array cable installation, installation could take up to 1.5 days per cable. For the maximum number of 740 array cables, this amounts to

1,110 days of array cable installation. Cable tail installation may take up to 20 days in total for 9 tails.

234. Durations for key elements of offshore construction are provided in **Table 4-17** below. It is important to note that many of the activities detailed may occur concurrently.

Table 4-17 Morlais Installation Durations

Activity	Predicted number of vessels on site	Indicative number of days vessels on site			Proportion of time vessels on site per year
		Over 10 year construction	Per year	Per year per sub-zone	
Cable tail installation	3 vessels (1 x cable tail installation vessel; 1 x cable tail installation support vessel; and 1 x dive support vessel)	200 days (assumes single operation of up to 15 days with 5 days extra for protection)	20 days	N/A (works in nearshore area not sub-zones)	5.48 %
Export cable installation	2 vessels (1 x cable installation vessel; and 1 x support vessel)	180 days (assumes 9 blocks of 20 days over 10yr period)	20 days (worst-case assumes that one 20 day block of activity occurs per year, for 9yrs of the 10yr build-out period)	Each 20 day block of export cable installation per year predicted to be spread across each of the 8 sub-zones	5.48 %
Export cable protection installation	3 vessels (1 x cable tail installation vessel; 1 x cable tail installation support vessel; and 1 x dive support vessel)	108 days (assumes 9 x blocks of 12 days following each block of export cable installation)	12 days (worst-case assumes that one 12 day block of activity occurs per year, for 9 yrs. of the 10yr build-out period)	Each 12 day block of export cable protection installation per year predicted to be spread across each of the 8 sub-zones	3.29 %
Inter-array cable Installation	2 vessels (1 x cable installation vessel; and 1 x support vessel)	1,110 days (assumes a 10 year period build out of all 8 arrays, and no more than 2 arrays built in parallel at any time)	111 days	Up to 13.75 days	30.14 %
Hub installation	2 vessels (1 x hub installation vessel; and 1 x support vessel)	1,800 days (assumes 15 days per hub for 120 hubs)	180 days	22.5 days (assumes total hub installation vessel days will be spread equally across the 8 sub-zones)	49.32 %

Activity	Predicted number of vessels on site	Indicative number of days vessels on site			Proportion of time vessels on site per year
		Over 10 year construction	Per year	Per year per sub-zone	
Tidal device installation	2 vessels (1 x construction vessel; plus 1 support vessel) Or 4 vessels (2 x construction vessel; plus 2 support vessel)	4,306 days	431 days	54 days (assumes total tidal device installation vessel days will be spread across the 8 sub-zones)	100 % & 18 % (assumes 1 x construction vessel plus 1 support vessel on sites every day; plus for 18 % of year assumes 2 x construction vessel plus 2 support vessels on site)

4.6.2. Onshore

235. A build out schedule for the onshore and landfall infrastructure of 24 months is planned (assuming all works can be carried out in parallel, not sequentially). The schedule would consist of the following:

- HDD at landfall lasting up to ten months;
- Substations (Landfall Substation and Grid Connection Substation) and Switchgear Building totalling 24 months duration. The work would mainly be running in parallel, with some activities staggered or phased. This includes:
  - Year 1: enabling works and civils
  - Year 2: electrical fit out and commissioning;
- Onshore cable circuit installation (including HDD for any crossings) lasting up to 18 months.

236. Working hours are expected to be:

- 24 hours per day and seven days per week for HDD and offshore cable tail installation; and
- Daylight only and six days per week for all other works.

237. This is summarised below in **Table 4-18**.

Table 4-18 Summary Table for Onshore Construction Schedule Parameters

Parameter	Value
HDD Schedule	10 months Working 24 hours per day and seven days per week
Substations schedule (Landfall and Grid Connection Substation)	24 months Daylight only / six days per week
Offshore cable tail schedule	Three months Working 24 hours per day and seven days per week
Onshore cable circuit schedule	Up to 18 months Daylight only / six days per week

4.6.2.1. Summary of Installation Works

238. Enabling works at the Grid Connection Substation, the Switchgear Building and the Landfall Substation may include:

- Surveying and measurement of sites, including pre-construction archaeology and ecological surveys and mitigation;
- Reinforcement or alteration of access roads;
- Creation of construction compounds (temporary laydown/construction areas and site office);
- Provision of electricity supply and other services to site;
- Construction of temporary security and site fencing;

- Tree and scrub clearance; and
- Foundation excavation.

239. Works at the Landfall Substation site may entail

- HDD between the transition pits and offshore HDD ‘break out’;
- Possible alternative method if HDD not feasible consisting of cutting of trenches with excavator / rock cutter and installation of marine cables from transition pit to shallow subtidal, including installation and pinning of ducting and cable to cliff face using split-pipe;
- Construction of transition pits to joint marine and non-marine cables;
- Installation (pulling in) of subsea cable tails; and
- Cable installation via trenching between transition pits and the Landfall Substation;

240. The following ancillary works may be undertaken in association with construction of the Landfall Substation and Grid Connection Substation building and outdoor compounds and the construction of the Switchgear Building;

- Creation of parking areas;
- Construction of foundations for buildings and plant;
- Construction of cable basements or cable pits;
- Possible construction / installation of screening and/or landscaping measures, including embankments and/or stone walls;
- Installation of transformers, switchgear and other electrical infrastructure within both substations;
- Termination of cables and wiring of electrical systems;
- Installation and termination of communications;
- Testing and commissioning activity; and
- Reinstate access roads/public rights of way and affected ground.

241. The following activities may be associated with the cable route trenching works;

- Construction of joint pits every 200 m to 900 m;
- HDD to enable crossings of watercourses and roads; and
- Reinstatement of access roads, public rights of way and affected ground.

4.6.2.2. Traffic and Staff

242. To understand the likely numbers of employees and Heavy Goods Vehicles (HGVs) that would be required for the onshore construction works, B&V have been commissioned to provide industry expertise and to develop the methodologies and quantities that underpin the traffic demand assumptions for the Project.

243. The construction workforce would consist primarily of specialist workers who travel to work on similar projects throughout the UK. To supplement this, local workers would be used where

possible, subject to required skills being available. The peak number of construction employees required has been estimated at up to 70 per day, further details regarding the likely split between the various construction activities is provided within **Table 4-19**.

244. **Table 4-19** also provides a summary of the forecast HGV movements for the respective construction activities. The numbers presented represent the peak periods for each construction activity. Further details of the traffic demand and derivation are provided within **Chapter 23, Traffic and Transport**.

Table 4-19 Vehicle Trips and Staffing Requirements for Onshore Construction Works

Activities	Peak two-way * daily HGV movements	Peak two-way * LGV ** movements	Peak all vehicle movements (two-way *)
Cable installation	6	24	30
Landfall substation and HDD	20	64	84
Inland substation and HDD	20	52	72
Total	**46**	**140**	**186**
Notes			
*	*A two-way movement represents the inbound (laden trip from source/home) and the outbound trip (back to source/home). For example, 20 two-way HGV movements comprise 10 laden trips from source and 10 outbound unladen trips back to source.*		
**	*LGV (Light Goods Vehicles) includes a range of vehicles, such as cars, vans, pickups, etc.*		

245. It is proposed that vehicles associated with the Landfall Substation, landfall HDD works and cable installation activities would first travel to the site compound at the Landfall Substation. From this point, vehicles associated with the cable installation would then travel onwards to their respective work fronts. Vehicles associated with the Grid Connection Substation and HDD works across the A55 would travel direct to these sites.

246. Upon completion of the construction there would additional vehicle movements to the Landfall Substation associated with installation of tenant equipment and periodic maintenance.

247. B&V have identified that during installation of tenant equipment within the landfall substation up to 30 employees would be required to travel to the Landfall Substation (60 two-way movements). In addition, up to four HGV deliveries per day (eight two-way movements) would be required.

248. Upon completion of the construction and developer equipment installation, there will be a requirement for periodic maintenance at the Landfall Substation and Grid Connection Substation. This is likely to result in a peak of 10 employees (20 two-way movements) per day.

249. To facilitate the safe access and egress from the public highways to the Landfall Substation and landfall HDD, a new access would be provided from South Stack Road. This access would be constructed prior to the commencement of construction and remain in place post construction for maintenance traffic.

250. The Grid Connection Substation would be accessed from existing accesses from the A5 London Road. Full details of the access requirements are contained within **Chapter 23, Traffic and Transport**.

4.6.2.3. Noise Emissions

251. A non-exhaustive list is included below in **Table 4-20** for plant creating notable noise in relation to the onshore works. All plant listed is relevant to construction.

Table 4-20 Noise Emission Figures for Onshore Construction Plant

Vehicle / plant	BS5228 Reference	LwA dB(A)	On time Correction	Comments
Tracked Excavator	C2.17	103.9	75 %	Will be used at all points of the works
Backhoe Loader	C2.8	95.8	75 %	Used at substations
Bulldozer	C2.11	106.9	75 %	Will be used at all points of the works
Dumper	C2.32	101.9	75 %	Will be used at all points of the works
Mobile Crane	C4.38	106.2	75 %	Used at substations
Cement Mixer Truck (Discharging)	C4.18	103.1	50 %	May be used at transition pits and substations
Truck Mounted Concrete Pump and Boom Arm	C4.32	105.8	50 %	Used along cable route and at substations
Dump Truck	C2.30	107.0	75 %	May be used along cable routes and at substations
Generator	89.4	89.4	100 %	May be used at all points of the works
Water Pump	C2.45	93.1	75 %	May be needed at various locations depending on ground water conditions
Lorry	C4.53	104.9	20 %	Will be used at all points of the works
Asphalt spreader and road roller*	C5.33	103.6	75 %	Used along cable route and at substations
Backhoe Loader	95.8	96	50 %	May be used along cable routes and at substations
HDD Drilling Rig	105.0	105.0	75 %	Likely needed at landfall and the A55/Railway crossing along at the Grid Connection Substation
Conveyor Drive Unit	C10.22	97.2	100 %	May be used along cable routes and at substations
Field Conveyor (Rollers)	C10.23	80.5	100 %	May be used along cable routes and at substations

4.7. OPERATION AND MAINTENANCE

4.7.1. Tidal Devices

252. Developers are expected to visit each tidal device up to 15 times annually for both planned and unplanned maintenance activities. Many developers plan to undertake at least monthly routine inspection / maintenance using small vessels. A worst-case scenario of one five-hour visit to each device on site per month may be foreseeable.

253. During maintenance activities a safety zone will apply around the O&M vessels. Offshore maintenance activities should be made available through Notices to Mariners.

254. Typical maintenance jobs may include: diagnostic tests, oil changes and lubrication, replacement of control cards and sensors, removal of biofouling, overhaul or replacement of systems (gearboxes, generators, switchgear etc.). Major operations such as retrieval and repair following structural failures would require similar vessels and procedures as installation works.

255. Maintenance procedures vary with device types with some tidal technologies having built in mechanisms to raise the devices to the water surface minimising the requirement for large maintenance vessels. Examples are as follows:

- TEC buoyant nacelle (remotely) released to surface and towed by a multicat or workboat to maintenance port. All work will be carried out onshore;
- Device designed for minimal interventions and high reliability (most critical systems are off the device), no gearbox or lubrication systems. TEC nacelle lifted with bespoke lifting frame via guide chains or similar. TEC disconnected from cable and taken to shore for work;
- Each TEC nacelle can be independently lifted from / lowered onto a seabed frame using a DP vessel or crane barge with moderate lifting capacity. Work on TECs will be carried out onshore. Lifting operations would typically take only a few hours each;
- Floating devices are designed so that it can be accessed at sea so that a large proportion of the maintenance can be carried out without removing the TEC from its moorings. These devices can, however, be towed by a small vessel to a nearby port for any major maintenance works; and
- Surface emergent, floating platforms are designed to be stable enough to carry out all but the largest of maintenance operations at sea. Access can be gained for some operations through surface emergent elements (transformers, control equipment etc.). Platform is raised (through variable buoyancy) for access to TEC. These can then be separately removed to shore for major work as necessary. Vessels for O&M would mainly be a workboat or multicat. For removal of tidal devices, a large multicat or possibly offshore DP vessel may be required.

256. For electrical hubs, requirements will vary depending on supplier and nature of the hub. Likely to require access several times a year. For fully submerged systems, the hub and foundation would either be lifted in its entirety or a buoyant hub may be remotely released and accessed by a much smaller vessel on the surface. Surface emergent hubs could be access using smaller

vessels on site and/ or be towed to shore for more major operations. A wide variety of DP vessels, heavy lift vessel, multicat, workboats and ROVs may be used.

4.7.2. Export Cables

257. It is expected that once installed, the ongoing offshore operations for the export cables will be limited to inspection (through survey) and maintenance of the cables and ancillaries.

258. The inspection regime for the offshore cables is expected to consist of annual inspections for the first two or three years reducing to every two years thereafter depending on the results of the initial surveys.

259. The inspections will be performed by an offshore survey vessel (including the use of an ROV) to assess the cables for any signs of damage or movement that has resulted in/from a free span. In the event of any cable movement to a position of concern, corrective action will either involve a (larger) work-class ROV to move that portion of the cable to a more stable location and/or the use of additional rock bags to lay over / under the cable in its new position.

260. As well as the scheduled maintenance operations it may be necessary to repair a subsea cable in the event of a failure or break. The most common cause of damage to a cable in offshore projects is from fishing trawl gear or anchor impact.

261. Repair of a cable will necessitate a vessel with suitable lifting and cable jointing equipment. The following process will be undertaken in this event:

    - Isolation of the requisite cable(s);
    - Location of the fault from onshore using suitable electrical techniques;
    - Location and assessment of the fault offshore using an offshore survey vessel (including the use of an ROV);
    - Cutting the cable subsea adjacent to the break on an area of ‘good cable’;
    - Lift the good end of the cable, check this part of the cable is undamaged;
    - Once check is satisfactory, buoy off good end and return to water;
    - Lift the damaged section of the cable, cut out any damaged length;
    - Splice on spare cable length;
    - Return to previously buoyed off end and joint to spare cable;
    - Return cable to the seabed;
    - Complete testing from onshore; and
    - Re-energise system.

262. It is anticipated that up to ten major cable repairs (five days each) may be required throughout the project life. It is assumed that up to 750 m of cable will be subject to repair works per event (From a total of 7,500 m). These will involve the same type of seabed disturbance and potential exclusion of other marine users due to the presence of cable repair vessel, as experienced via

the main cable installation phase. However, any such disturbance will be much more temporally and spatially limited.

263. Annual maintenance of navigational buoys and any environmental monitoring equipment will also be required. These works will be undertaken using a workboat with small crane. The buoys or ADCP frames will be lifted onto the vessel from which appropriate maintenance can be carried out, this will include cleaning to remove marine growth, bulb replacement for buoys; diagnostic tests and battery replacement for ADCPs.

4.8. REPOWERING

264. The Project is a tidal technology demonstration project and it is anticipated that the tidal devices/arrays may be replaced several times within the 37-year project life.

265. A repowering of a device/array is defined as the end of a berth/array demonstration cycle, at which time the TECs, device foundations, support structures, electrical hubs, tenant monitoring equipment, and inter-array cabling may be removed, in line with procedures adopted during decommissioning (see **Section 4.9**). Once the developer owned assets listed above have been removed, the Project will then have capacity for ‘repowering’ when tidal devices within existing arrays may be replaced at the same berth, or full arrays may be replaced with new arrays deployed at a new location.

266. Once all the tenant’s infrastructure has been removed, the specifications of any new array would be reviewed by regulators against the consented PDE following an agreed consent management regime. Construction of new devices will be undertaken in accordance with the construction procedures for device foundations, support structures, TECs, electrical hubs, tenant monitoring equipment, and inter-array cabling outlined in **Section 4.5**.

267. Export cables, export cable protection, navigational markers and onshore infrastructure will remain in place for the life of the Project.

268. The repowering process differs from O&M activities where, for example, the TEC may be removed for maintenance, whilst the other infrastructure (e.g. foundations) would remain *in situ*.

269. For the purpose of defining impact assessment parameters for the repowering phase, an assumption has been made that 50% of the tenants will undertake repowering, i.e. for 50 % of the tenants, their infrastructure will be removed and replaced (potentially with different infrastructure by a different tenant). For the other 50 % of tenants, their infrastructure will remain over the lifetime of the project.

270. In terms of impact assessment parameters, the repowering process has been defined as per below:

- Initial temporary seabed disturbance via deployment of barge anchors to <u>remove</u> foundations, TEC’s, hubs, inter-array cables and monitoring equipment for 50 % of the Tenants (berths);

- Further temporary seabed disturbance via re-installation (repowering) of foundations, TEC's, hubs, inter-array cables and monitoring equipment for the same 50 % of Tenants (berths); and
- Additional permanent habitat loss (over and above that via initial construction phase), due to placement of re-installed (repowered) foundations/TECs in different areas to where originally installed.

271. The quantified values for this activity are presented below in **Table 4-22**.

4.9. DECOMMISSIONING

272. Although contractual details have not been finalised, decommissioning of individual devices and arrays will be the responsibility of the individual tenants. However, Menter Môn holds ultimate responsibility for decommissioning of the Project, and the decommissioning of general infrastructure will be the direct responsibility of Menter Môn.

273. Offshore decommissioning methodologies would vary considerably between devices but would be expected to be similar to the construction phase in reverse. For the purpose of this ES, it is assumed that offshore cables are required to be removed as this represents the worst-case scenario in terms of impacts.

274. At the end of the intended Project lifetime of 37 years, the Project is likely to be decommissioned or re-powered. The decommissioning phase is expected to be as below, for the purposes of the ES:

- Cables will be re-used, preserved *in situ* or removed. Removal is considered as the worst-case scenario;
- Cable protection material will be left *in situ* on the sea bed, assuming that it causes no unacceptable impacts or hazards;
- Gravity base foundations (including gravity anchors) may be left *in situ* while piles would be cut to an acceptable seabed level;
- All other components of the tidal devices (i.e. TECs, superstructure and support structure) will be removed;
- Any electrical hubs will be removed; and
- Navigation buoys and site monitoring equipment and their foundations / moorings will be removed for re-use.

275. At this stage, decommissioning of onshore electrical infrastructure is expected to consist primarily of removal of the onshore substation. Any cables that might be laid on the surface within the onshore Development Area would be terminated and it left *in situ*. All structures laid upon the cliff face and foreshore will be removed upon decommissioning, any buried cables will remain *in situ*.

276. For the purposes of the EIA, the PDE will include a worst-case scenario for the decommissioning against which the assessment of impacts will be undertaken.

4.10. PROJECT DESIGN ENVELOPE SUMMARY

277. This section summarises the PDE and provides an overview of the worst-case scenarios of the key components of the project description which are taken forward in impact assessments.

278. **Table 4-21** to **Table 4-28** summarise the PDE.

Table 4-21 Generic Project Parameters

Parameter	Maximum value
MDZ area	35 km^2
ECC area	4.75 km^2
ODA area	1 km^2
OfDA area (MDZ plus ECC)	39.75 km^2
Intertidal area	0.0151 km^2
Project life	37 years
Project installed capacity	240 MW
Tidal Energy Converters	1,648
Number of Export cables	9
Total length export cables	40.5 km
Number of Inter-array cables	740
Total length inter-array cables	204.5 km
HDD ducts	9
Transition pits or bays	9
Export cables and export cable tails	9
Landfall substation	1
Switchgear building	1
Grid Substation	1

Table 4-22 Worst-Case Number of Tidal Devices for Each Device Type

Tidal Device Type	Number of devices
Floating / Surface emergent	Up to 130*
Buoyant mid-water and/or seabed mounted fully submerged	Up to 490
TOTAL	**Up to 620 ****
* Worst case scenario for surface emergent devices detailed in paragraphs 104 and 117, as well as Chapter 25 SLVIA. ** See paragraphs 36 and 60.	

Table 4-23 Tidal devices and TECs worst-case parameters[11]

Parameter	Maximum value
TEC output	4 MW [12]
TEC diameter	27 m
TEC average speed	22 rpm
Height above sea level (for floating device)	6.5 m
Length	72 m
Width	30 m
Device spacings within arrays	See **Table 4-9**

Table 4-24 Hubs and buoys worst case parameters[13]

Parameter	Maximum value
Number of hubs	120
Height of hubs above LAT	18 m
Navigation (including IALA Cardinal marks) and marker buoys	60
IALA Cardinal Marks	4
ADCPs	40
Monitoring buoys (in addition to Navigation and marker buoys	5

Table 4-25 Worst-Case Foundation, Mooring and Footprint Parameters (Operational (Repowering) phase)

Parameter	Construction Phase	Repowering
Maximum seabed footprint of devices	74,790 m^2	37,395 m^2
Export Cable Footprint (cables and protection systems + rock bags)	11,745 m^2	NA
Array Cable Footprint (cables and protection systems + rock bags every 100m)	30,040 m^2	15,020 m^2
Landfall trench for nine landfall cables	7,400 m^2	NA
Maximum footprint cable tails	120 m^2	NA
Maximum footprint of 40 ADCPs	280 m^2	NA
Footprint of eight seabed mounted environmental monitoring units	112 m^2	66 m^2
Footprint of 60 Navigation and Marker Buoy moorings	540 m^2	NA

[11] This table is drawn from review of parameters of multiple tidal devices and TECS, to identify the worst case or maximum value for each parameter. It does not refer to one single device example.
[12] 4 MW anticipates improvements of design and efficiency of tidal technologies over the time of the project to allow for a greater installed capacity per device, with all other maximum PDE values unchanged, and up to the maximum installed capacity of the Project of 240MW.
[13] This table is drawn from review of parameters of monopile, floating and seabed hubs to identify the worst case or maximum value for each parameter. It does not refer to one single hub type example.

Parameter	Construction Phase	Repowering
Footprint of five sea level environmental monitoring buoy moorings	45 m^2	22.5 m^2
Swept area from Catenary	2,055,000 m^2	NA
Drilled pin pile foundations	5,889 m^2	2,944.5 m^2
Drilled socket arisings	117,780 m^3	58,890 m^3
Drilling footprint	5,889 m^2	2,944.5 m^2
Drilling time	3,990 days	1,995 days

Table 4-26 Worst-Case Parameters for Temporary Seabed Disturbance (Construction, O&M (Repowering) and Decommissioning phases)

Parameter	Entire Site	Comment
Construction Phase:		
Post-lay cable management	27,259 m^2	Area of sandwave field where post-lay works with Mass-Flow Excavator (MFE) may be required if surface laid cable shows areas of suspended cable.
Deployment of anchor blocks by barges during cable installation	100,240 m^2	Temporary disturbance arising from mooring footprints. Up to eight 25 m^2 (5 m by 5 m) anchor blocks for a single barge equal to a total footprint per anchor deployment of 200 m^2. Assumed that these types of anchor barges generally deploy a spread every 500 m. So, for every 500 m of cable installation a footprint of 200 m^2 of temp seabed disturbance occurs (via the anchor blocks). Total cable length = 250.6 km (Exports: 40.5 km Inter-Arrays: 203.5 km Cable Tails: 5.6 km) So, assuming the footprint of 200 m^2 every 0.5 km, or 400 m^2 every 1 km, and assuming all cables are installed using anchor barges, temporary disturbance impact equal to 100,240 m^2 (0.10 km^2).
Deployment of anchor blocks by barges during tidal device installation	248,000 m^2	Max. no of devices set at 620 x small (0.2 kW devices) Assumed that deployment of each device requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2)

Parameter	Entire Site	Comment
		Therefore, total temporary seabed disturbance = 620 x 400 m^2 = 248,000 m^2
Deployment of anchor blocks by barges during hub installation	48,000 m^2	Maximum number of seabed mounted hubs is set at 120. Assumed that deployment of each hub requires two anchor deployments from barge (equal to 400 m^2). Therefore, total temporary seabed disturbance is equal to 48,000 m^2.
Construction Phase TOTAL	**423,499 m^2 (0.42 km^2)**	
Operational Phase:		
50 % of tenants' infrastructure (Foundations; TEC's; hubs' array cables; monitoring equipment) removed and replaced with new (different) tenant infrastructure	377,400 m^2	Initial <u>removal</u> of tenant infrastructure from 50 % of berths • 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 • 50 % of anchor block value of tidal device installation = 124,000 m^2 • 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2 Subsequent <u>re-installation (re-powering)</u> of tenant infrastructure from 50 % of berths • 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 • 50 % of anchor block value of tidal device installation = 124,000 m^2 • 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2
Cable repairs	3,000 m^2	Up to 10 major cable repairs (five days each) may be required throughout the project life (assumed that cables will be surface-laid). It is assumed that up to 750 m of cable will be subject to repair works per event (7,500 m in total).

Parameter	Entire Site	Comment
		Anchor deployments at of 400 m^2 temp seabed disturbance per 1 km of cable works is equal to 3,000 m^2.
Operational Phase TOTAL	**380,400 m^2 (0.38 km^2)**	
Decommissioning Phase:		
Decommissioning Phase	Same worst-case as per construction phase due to same activities needed to remove infrastructure.	
Decommissioning Phase TOTAL	**423,499 m^2 (0.42 km^2)**	

Table 4-27 Maximum Weight of Offshore Infrastructure Deployed

Infrastructure	Weight
Steel	193,333 tonnes
Concrete	466,667 tonnes
TOTAL	**660,000 tonnes**

Table 4-28 Worst-Case Onshore Infrastructure

Parameter	Value
Landfall Substation	
Fenced compound	80 m by 80 m or equivalent area.
Buildings	Building A: 62 m by 22.5 m (or equivalent area) x 7 m high Building B: 28 m by 10 m (or equivalent area) x 7 m high Building C: 8 m by 8 m (or equivalent area) x 7 m high Building C is within a plant compound: 28 m x 36 m (or equivalent area) x 7 m high.
Temporary construction compound	50 m x 100 m or equivalent area.
Substation perimeter fencing	Weld steel 1.8 m tall.
Palisade fencing	Hidden within perimeter fence 2.4 m tall.
Access / egress	Via new entrance South Stack Road.
Surfaces	Hard standing 5 m to 7 m wide on access roads and access within substation. Outdoor areas other than hard standing crushed rock 80 mm to 150 mm deep.
Foundations	Concrete slab foundations. Slip and slab if possible. Alternative piled solution if ground conditions require.
Cut and fill volumes	Approximately 13,900 m^3 cut and approximately 130m^3 fill.
Drainage	Foul drainage to septic tank. Surface water via oil interceptors (as required) to water course, septic tank or soakaway.
Lighting	110 lx directed lighting. Lit only as needed. Motion sensor activated.
Other	Facility for electric vehicle charging.
Switchgear Building	
Fenced compound	N/A
Building	Single building up to 9.4 m x 5 m, with a maximum height of 4 m.

Parameter	Value	
Temporary construction compound	30m x 20 m or equivalent area.	
Palisade fencing	N/A	
Access / egress	Access via the existing road to Parc Cybi employment site	
Surfaces	N/A	
Foundations	Concrete slab foundations. Slip and slab if possible. Alternative piled solution if ground conditions require.	
Drainage	Surface water via oil interceptors (as required) to water course, local sewerage, or soakaway.	
Lighting	110 lx directed lighting. Lit only as needed. Motion sensor activated.	
Grid Connection Substation		
Fenced compound	104 m x 62 m or equivalent area.	
Buildings	Buildings and plant to maximum height of 9 m.	
Temporary construction compound	50 m x 100 m or equivalent area.	
Palisade fencing	2.4 m height palisade fencing.	
Access / egress	Access via existing road to Orthios site.	
Surfaces	Hard standing 5 m to 7 m wide on access roads and access within substation. Outdoor areas other than hard standing crushed rock 80 to 150 mm deep.	
Foundations	Concrete slab foundations. Slip and slab if possible. Alternative piled solution if ground conditions require.	
Drainage	Foul drainage to local sewerage network, or to septic tank. Surface water via oil interceptors (as required) to water course, local sewerage, or soakaway.	
Lighting	110 lx directed lighting. Lit only as needed. Motion sensor activated.	
Onshore cables		
Cables from transition pit to Landfall substation	From transition pit to Landfall Substation, each of the 9 onshore cables will require up to 8 ducts depending on the specific requirements of the tidal energy devices. The maximum case of 8 ducts comprises, 3 x HV, 1 x fibre optic, 1 x LV and a spare, 1 x Extra Low Voltage and a spare. The minimum case of 2 comprise a single, multi-core HV cable and a fibre optic. This gives a maximum case of 72 ducts.	
Cables from Landfall Substation to Grid Substation	Six power cables and two fibre optic cables. Each to a maximum 110 mm diameter.	
Cable route length	Up to 8.1 km, depending on route finalisation	
Installation method	Cables will be laid in ducts installed into trenches. Trenches will be laid into the road and adjacent verge / field area areas.	
Trench parameters (per section)	Landfall Substation to Grid Connection Substation	Switchgear Building to Grid Connection Substation
Circuit	132 kV	33 kV
Trench depth	1620 mm	1620 mm
Trench width	1400 mm	2000 mm
Length	6675 m	1420 m

Parameter	Value	
Joint pits (No.)	18	2
Joint pits chamber depth	1.65 m	1.65 m
Joint pits chamber width	2 m	3 m
Joint pits chamber length	12.5 m	5 m
Draw pits (to be fully reinstated following works) (No.)	35	7
Draw pit depth	1.65 m	1.65 m
Draw pit width	3 m	5 m
Draw pit length	8 m	8 m
Hard standing	20 m x 7 m hardstanding at each joint bay.	

4.11. SUMMARY

279. The Project details for the MDZ described in this chapter have been considered by for the parameters relevant to each receptor. **Chapters 7** to **26** outline the worst-case scenario for each relevant receptor and this is used as the basis for assessing the impacts. By assessing the worst-case scenario per receptor, it is deemed that this provides the maximum potential impact for assessment.

5. EIA METHODOLOGY

5.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) describes the Environmental Impact Assessment (EIA) process and the methodology used throughout the ES assessment chapters for the Morlais Project (the Project).

2. The purpose of the EIA is to inform the decision-maker, stakeholders and all interested parties of any significant environmental issues that may result from the Project during its construction, operation and (where relevant) decommissioning. The EIA provides an independent assessment of the Project to enable interested parties to understand such potential impacts before making decisions on whether consent for the Project should be granted.

3. This section sets out the approach for the assessment of impacts which has been adopted within this ES. In summary, this chapter presents:

    - Details of the guidance followed throughout the EIA;
    - A summary of the EIA process;
    - The approach adopted to define the baseline environment (specific details are provided for each environmental topic considered in the relevant chapter);
    - The generic approach taken to assess potential impacts, including the evaluation of significance (where a different approach has been adopted for a specific topic, this is set out in the relevant chapter);
    - The generic approach taken to the derivation of mitigation measures and the assessment of residual impacts; and
    - The approach taken to the assessment of potential cumulative impacts.

4. This chapter provides an overview of the generic approach taken to impact assessment across all EIA topics. It should be noted that topic specific methodology is covered in each technical chapter (**Chapters 7 to 26**) as the exact methodology for the receptors of each topic need to be relevant to those receptors (e.g. in terms of definitions of sensitivity or magnitude of effect).

5.2. EIA GUIDANCE

5. As discussed in **Chapter 2, Policy and Legislation**, the legislative framework for EIA is set by Directive 97/11/EC (“the EIA Directive”). This Directive has been transposed into UK law through a number of regulations applicable to different categories of development, which require an EIA to be undertaken to support the consent application.

6. The following consents are required for the Project:

    - A Marine Licence under the Marine and Coastal Access Act 2009;
    - A Transport and Works Act Order under the Transport and Works Act 1992.

7. The requirement to comply with the EIA Directive is transposed into law by amendments to the Transport and Works Act 1992 and Transport and Works (Applications and Objections

Procedure) (England and Wales) Rules 2006 and the Marine Works (EIA) (Amendment) Regulations 2017. The Project also falls under the Marine and Coastal and Access Act (2009).

8. For applications under the Transport and Works Act 1992, including deemed planning permission, the consenting body will be the Welsh Government, while for Marine Licenses under the Marine Coastal and Access Act (2009), Natural Resources Wales (NRW) are the licensing body.

9. This EIA has been undertaken in accordance with the requirements of the above regulations and has taken into account key policies, legislation, guidance and advice, including but not limited to the following:

- Ministry for Housing, Communities and Local Government (MHCLG) “Guidance: Environmental Impact Assessment” (2017);
- Chartered Institute of Ecology and Environmental Management (CIEEM) “Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater, Coastal and Marine” (2018);
- Institute of Environmental Management & Assessment (IEMA) “Guidelines for Environmental Impact Assessment” (2017);
- Planning Policy Wales (2018);
- Draft Welsh National Marine Plan (2017); and
- The Wildlife and Countryside Act 1981.

10. It is noted that this list of guidance is not exhaustive and the relevant guidance adopted for the assessment of each environmental parameter is described in the relevant topic chapter.

5.3. THE EIA PROCESS

5.3.1. Process Overview

11. EIA is a systematic process, which identifies the potential effects of proposed works and how these translate into impacts upon the receiving environment. This process includes an assessment of the likely significance of any potential impacts and the identification of a range of suitable mitigation options and management measures. The EIA process is designed to be as transparent as possible incorporating an ongoing consultation process with statutory and non-statutory consultees. The EIA process has a number of distinct stages as follows:

- **Scoping** – a formal process requesting an opinion on the Project from statutory consultees, coordinated by the Welsh Government (WG). The scoping process also identifies the existing environmental data present and the key issues at the site, thereby identifying any additional studies that are required for their assessment;
- **Baseline studies** – undertaken to identify the current status of the receiving environment and to identify the requirement to carry out further desk and field studies;
- **Project definition** – development of the project details under a Rochdale Envelope or Project Design Envelope (see **Chapter 4, Project Description** for more information on

project definition and **Chapter 2, Policy and Legislation** for more information on the Rochdale Envelope approach);

- **Assessment of impacts** – the assessment of the significance of the potential impacts related to the Project, as well as the proposed mitigation and the resulting residual impacts;
- **Environmental reporting** – compilation of the ES and the supporting documentation (e.g. appendices and technical reports); and
- **Submission and consenting** – the submission of the ES, information to support a Habitats Regulations Assessment (HRA), and the appropriate consent applications. These documents go through a determination process with the appropriate consenting body.

12. The EIA is based on the expert judgement of technical specialists, following an appraisal of the parameters included in the Rochdale or Project Design Envelope (PDE) as described in **Chapter 4, Project Description**. The process is outlined in **Table 5-1**.

Table 5-1 Stages of the ES Preparation

Stage	Task	Aim/Objective	Work/Output (Examples)
EIA	Consultation – throughout EIA process	Consult with statutory and non-statutory organisations	Local knowledge and information
	Primary Data Collection	To identify the baseline/ existing environment	Background data including existing literature and specialist studies
	Specialist Studies	To further investigate those environmental parameters which may be subject to potentially significant effects	Specialist reports (e.g. hydrodynamic modelling and archaeological assessment)
	Impact Assessment	To evaluate the baseline environment in terms of sensitivity To evaluate and predict the impact (i.e. magnitude) upon the baseline To assess the resultant effects of the above impacts (i.e. determine significance)	Series of significant adverse and beneficial impacts
	Mitigation Measures and Monitoring Requirements	To identify appropriate and practicable mitigation measures and enhancement measures and outline any recommended monitoring.	The provision of solutions to avoid offset or reduce adverse impacts (e.g. sensitive scheduling to avoid noise and traffic impacts) Feedback into the design process, as applicable.
	Draft ES	Production of the ES in accordance with EIA guidance	ES
	Finalise ES	Submission of the ES to WG	ES

13. EIA is a tool for systematically identifying, examining and assessing the impacts and effects of the construction, operational and, if applicable, decommissioning phases of the proposed scheme on the environment. The process of identifying and assessing the environmental impacts of the proposed Project is iterative, running in parallel with the project design. Where any of the potential impacts are identified as being significantly adverse then, where possible,

the design will be altered to mitigate these impacts. Consultation is ongoing throughout the EIA process and contributes to the identification of both impacts and associated mitigation measures.

14. The formal reporting mechanism for an EIA is the ES. In accordance with regulations, the ES should include such information as is reasonably required to assess the likely significant environmental effects of the proposed scheme and which the applicant can reasonably be required to compile. **Table 5-2** summarises the information requirements and where these can be found within the ES.

Table 5-2 Information Requirements of an ES

Information Required for Inclusion in the ES	Reference within the ES
▪ A description of the Project and of the regulated activity, including in particular: ▪ A description of the location of the Project and the regulated activity; ▪ A description of the physical characteristics of the whole Project and regulated activity, including where relevant, requisite demolition works, and the land-use requirements during the construction and operational phases; ▪ A description of the main characteristics of the operational phase of the Project and the regulated activity (in particular any production process); ▪ An estimate, by type and quantity, of expected residues and emissions resulting from the operation of the proposed Project and the regulated activity.	**Chapter 4, Project Description**
▪ A description of the reasonable alternatives.	**Chapter 3, Site Selection and Consideration of Alternatives**
▪ A description of the relevant aspects of the current state of the environment (baseline scenario).	**Chapters 7 to 26**
▪ A description of the factors likely to be significantly affected by the Project and the regulated activity: population, human health, biodiversity, land, soil, water, air, climate, material assets, cultural heritage, including architectural and archaeological aspects, and landscape.	**Chapters 7 to 26**
▪ A description of the likely significant effects of the Project and the regulated activity on the environment.	**Chapters 7 to 26**
▪ The description of the likely significant effects on the factors must cover the direct effects and any indirect, secondary, cumulative, transboundary, short-term, medium-term and long-term, permanent and temporary, positive and negative effects of the Project and the regulated activity. This description must take into account the environmental protection objectives established at Union or member State level which are relevant to the Project and the regulated activity.	**Chapters 7 to 26**
▪ A description of the forecasting methods or evidence used to identify and assess the significant effects on the environment including details of	**Chapters 7 to 26**

Information Required for Inclusion in the ES	Reference within the ES
difficulties encountered compiling the required information and the main uncertainties involved.	
▪ A description of the measures envisaged to avoid, prevent, reduce or if possible offset any identified significant adverse effects on the environment and, where appropriate, of any proposed monitoring arrangements.	**Chapters 7 to 26,** Outline Construction Environment Management Plan (**Document MOR/RHDHV/DOC/0073**) and Outline Environment Mitigation and Monitoring Plan (**Document MOR/RHDHV/DOC/0072**)
▪ A description of the expected significant adverse effects of the Project and the regulated activity on the environment deriving from the vulnerability of the Project and the regulated activity to risks of major accidents or disasters which are relevant to the Project and the regulated activity concerned.	**Chapters 7 to 26**
▪ A non-technical summary.	**Non-Technical Summary**
▪ A reference list detailing the sources used for the descriptions and assessments included in the report.	**Chapters 7 to 26**

15. The approach adopted in the EIA process for the Project is summarised in the following sections. It should be noted that these stages are not necessarily consecutive and may overlap. For example, iterative design changes may be made in light of emerging findings of the EIA process to prevent or reduce the significance of a potential impact. This would then require re-assessment of the potential impact, potentially informed by further survey work to adequately describe the baseline environment.

5.3.2. Screening

16. An inception meeting regarding the Project's proposed consenting route was undertaken with the Planning Inspectorate and the Welsh Government on 15th March 2018 at which the need for EIA to support consent applications was confirmed and appropriate consenting requirements for the Project were agreed. Following discussions within this meeting, Menter Môn is seeking to consent via the following legislative mechanisms:

- Transport and Works Act 1992 because the Project has the potential to interfere with rights of navigation in waters up to the limits of the territorial sea); and
- Marine and Coastal Access Act 2009 as the Project will involve the placement of materials on and above the seabed.

17. A detailed summary of the legal framework for the Project is provided in **Section 2, Policy and Legislation**.

5.3.3. Scoping

18. The purpose of the scoping process is to identify the principal environmental issues at the earliest possible stage of the development process through responses from the regulators and their consultees. This assists in the appropriate targeting of the assessment studies and the

identification of which elements of the Project have the potential to cause significant environmental impacts.

19. The consultation process may identify mitigation measures and, where practicable, take account of the view of consultees to alter the project design, thereby avoiding or reducing any environmental or human impacts. Menter Môn regards the consultation process as being important to the success of the Project and have therefore undertaken a significant amount of public and stakeholder engagement, as well as additional consultation with statutory consultees beyond the scoping and submission processes. The consultation undertaken and key topics covered are detailed in **Chapter 6, Consultation**.

20. Regulation 8 of the Transport and Works (Applications and Objections Procedure) (England and Wales) Rules 2006 outlines that before submitting an application in relation to works for which an EIA is or may be required, the applicant may request in writing to the Secretary of State his opinion as to the information to be provided in the ES (a scoping opinion).

21. Two earlier scoping reports have previously been submitted to NRW, the Marine Management Organisation (MMO) and the IoACC; however, these are now superseded as a result of further development in the project design concept. The proposed installed capacity of the Project has been increased in response to industry demand, and the Project is now seeking consent for an array of up to 240 MW capacity and associated supporting infrastructure.

22. As a result, a third Scoping Report (superseding previous Scoping Reports) was produced by Royal HaskoningDHV on behalf of Menter Môn and submitted to the Welsh Government, with a request for screening and scoping opinion, by Menter Môn on 6th April 2018.

23. A version of the Scoping Report was also sent to NRW with a request for Scoping Opinion to inform an EIA as required under The Marine Works (Environmental Impact Assessment) Regulations 2007, as amended by The Marine Works (Environmental Impact Assessment) (Amendment) Regulations 2017.

24. RHDHV and MarineSpace have ensured the ES clearly demonstrates how the comments received from the regulators and their statutory consultees for both key consents (Transport and Works Act Order (TWAO) and Marine Licence) are addressed. This is done via a ‘signposting’ table outlining the scoping response received and the location within the ES where the comment is addressed.

25. Each technical chapter (**Chapters 7 to 26**) outlines the key issues pertinent to that issue which have been identified through the scoping process.

5.3.4. Environmental Statement

5.3.4.1. Environmental Baseline

26. The term ‘baseline environment’ is used to describe the nature, scale, condition, and other relevant information to provide a detailed description of a given environmental receptor that falls within the scope of the ES.

27. Characterisation (a description) of the baseline environment has been undertaken in order to determine the baseline conditions in the area covered by the Project and relevant study areas. This has been undertaken following the steps below. These steps are also detailed further within each assessment chapter, where relevant:

- Definition of study areas for each receptor, based on the relevant characteristics of the receptor;
- Review of available information;
- Review of likely or potential impacts that might be expected to arise from the Project;
- Review of whether sufficient information is available to make EIA judgements with sufficient confidence;
- If further data is required, ensure data are gathered, targeted and directed at filling key data gaps; and
- Review further data to ensure sufficient information is available to make EIA judgements with sufficient confidence.

28. Within this ES, the description of the baseline environment consists of the following aspects:

- the spatial location and extent of the environmental features or receptors;
- a description of the environmental features or receptors and their character;
- the context of the environmental features or receptors in terms of rarity, function, and population at the local, regional and national level;
- the sensitivity of the environmental features or receptors in relation to physical, chemical or biological changes; and
- the value of the environmental features or receptors (e.g. designated status).

29. A wide range of information has been gathered and activities undertaken to define the baseline environment and likely receptors. These data sources are detailed in each chapter and include, but are not limited to the following:

- Desk-based review of existing published data;
- Data provided by consultees; and
- Field survey and site investigation information.

30. The results of the environmental baseline studies are outlined in **Chapters 7** to **26** of this ES.

5.3.4.2. Project Design Envelope

31. An essential element of any EIA is defining the project description against which impacts will be assessed. Due to the nature of the Project and the evolving nature of the tidal energy sector, full details of the proposed Project are not available at the time of the application. Therefore, the project description and methods upon which this application for consent is based, fall within a range of defined criteria. This Project Design Envelope approach, often referred to as a 'Rochdale Envelope', allows a degree of flexibility in determining the final specific Project details,

while still meeting the requirements of the EIA process. This approach is outlined in more detail in **Chapter 2, Policy and Legislation.**

32. The approach defines a series of realistic maximum extents and magnitudes for the description of a development, so that a realistic 'worst case scenario' is assessed. **Chapter 4, Project Description** sets out the parameters of the Project which form the basis of the ES. Each technical chapter (**Chapters 7** to **26**) provides an outline of the relevant worst case for that receptor. Post consent, a detailed design of the scheme can vary within that envelope, without rendering the EIA inadequate. By adopting this approach, the ES can conclude that the environmental impact of the Project will be no greater than that set out in the ES and may actually be less.

5.3.4.3. Impact Assessment

33. The approach to making balanced assessments for the Project has been guided by Royal HaskoningDHV, MarineSpace and technical specialists using available data, new data, experience and expert judgement. In order to provide a consistent framework and system of common tools and terminology, a matrix approach has been used to frame and present the judgements made.

34. This section sets out the assigned definitions that are used in the assessment process for a number of topics considered in the ES. For each topic of the EIA, the most relevant and latest guidance or best practice has been used and therefore definitions of sensitivity and magnitude of impact are tailored to each receptor. A description of the approach taken to the specific impact assessment for each environmental receptor is provided (in each relevant chapter) so that it is clear to the reader how impacts have been defined, particularly where such an approach differs to that described within this section.

35. The impact assessment considers the potential for impacts during the construction, operation and maintenance, and decommissioning phases of the Project.

36. EIA provides an assessment of the impacts on sensitive receptors as a result of the effects of a development upon the environment. The terms 'effects' and 'impacts' have, in the past, been used interchangeably, but they are in fact different and one drives the other. Effects are physical changes in the environment that are set in motion as a consequence of a particular development or activity. Effects do not impact all receptors, as some receptors are not always sensitive to them.

37. Effects are measurable physical changes in the prevailing environment (e.g. volume, time and area) arising from construction and operation activities. Effects can be classified as primary (e.g. the physical presence of a built element of the development) or secondary (e.g. increase in erosion due to a change in the rate of discharge of surface water). Impacts consider the possible changes in potentially sensitive receptors as a result of an effect.

38. Impacts can be classified as follows:

- Direct impacts: these may arise from impacts associated with the construction, operation and maintenance, or decommissioning of the Project;
- Indirect impacts: these may be experienced by a receptor that is removed (e.g. in space or time) from the direct impact (e.g. noise impacts upon fish which are a prey resource for fish or mammals).
- Inter-relationships between impacts; or
- Cumulative impacts: these may occur as a result of the Project in conjunction with other existing or planned projects within the study area for each receptor.

39. The EIA framework used herein is based on the ‘source-pathway-receptor’ conceptual model process used to provide a systematic and auditable approach to understanding the potential for effects to arise, the spatial extents of the effect-receptor interactions, impact pathways, and potential impact significance. The conceptual ‘source-pathway-receptor’ model is effective in the identification of potential effects and the means by which these can manifest themselves on the receiving environment and its sensitive receptors.

40. The term ‘source’ describes the origin of potential effects (e.g. construction activities) and the term ‘pathway’ describes the means (e.g. through air, water, or ground) by which the effect reaches the receiving sensitive ‘receptor’ (e.g. terrestrial habitats, archaeology and human receptors). If the source, pathway or receptor is absent, no linkage exists and thus there will be no potential for an impact to manifest.

41. For each effect, the assessment identifies receptors within the study area that are sensitive to that effect and implements a systematic approach to understand the impact pathways and the level of impacts on given receptors. The process considers the following:

- The sensitivity of a receptor to the effect;
- The probability that an effect-receptor interaction will occur;
- The magnitude of the effect;
- The determination and (where possible) qualification of the level of impact on a receptor, considering the probability that the effect-receptor interaction will occur, the spatial and temporal extents of the interaction and the significance of the resulting impact; and
- The level of certainty at all stages.

5.3.4.3.1. Receptor Sensitivity

42. All receptors will exhibit a degree of sensitivity to the changes brought about by the Project and defining receptor ‘sensitivity’ as part of the definition of the baseline environment helps to ensure that the subsequent assessment is transparent and robust. The characterisation of the existing environment helps to determine the receptor sensitivity in order to assess the potential impacts upon it.

43. The ability of a receptor to adapt to change, tolerate, and/or recover from potential impacts is key in assessing its sensitivity to the impact under consideration. For ecological receptors, tolerance could relate to short term changes in the physical environment; for human environment receptors, tolerance could relate to impacts upon socio-economics or health impacts. The time required for recovery is an important consideration in determining receptor sensitivity.

44. The overall receptor sensitivity is determined by considering a combination of value, adaptability, tolerance and recoverability. This is achieved through applying known research and information on the status and sensitivity of the feature under consideration coupled with professional judgement and past experience.

45. In summary, the sensitivity of a receptor is a function of its capacity to accommodate change and reflects its ability to recover if it is affected, and is defined by the following factors:

- Vulnerability: whether a particular effect has the ability to impact a receptor;
- Adaptability: the degree to which a receptor can avoid or adapt to an effect;
- Tolerance: the ability of a receptor to accommodate temporary or permanent change without a significant adverse effect;
- Recoverability: the temporal scale over, and extent to, which a receptor will recover following an effect; and
- Value: a measure of the receptor's conservation importance, rarity and worth (see **Section 5.3.4.3.2**).

46. In order to define the sensitivity of a receptor, the guidelines presented in **Table 5-3** have been adopted in this ES.

Table 5-3 Definitions of the Sensitivity Levels for Environmental Receptors

Sensitivity	Description
High	Individual receptor has very limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Medium	Individual receptor has limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Low	Individual receptor has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact.
Negligible	Individual receptor is generally tolerant to and can accommodate or recover from the anticipated impact.

47. It should be noted that the sensitivity criterion is a composite one; combining value (see **Section 5.3.4.3.2**) with sensitivity. In some instances, the inherent value of a receptor is recognised by means of designation, and the 'value' element of the composite criterion recognises and gives weight in the assessment to that designation. However, irrespective of the recognised value, all receptors will exhibit a greater or lesser degree of sensitivity to the potential changes brought about by the proposed scheme. It should be noted that the assessment of sensitivity is a matter of judgement applied by professional experts based on the receptors within the relevant study area.

48. Sensitivity to potential impacts is considered for each species, using available evidence including published data sources. The conclusions reached regarding the sensitivity of receptors have been presented in the baseline sections of each technical chapter (**Chapters 7 to 26**).

5.3.4.3.2. Receptor Value

49. Receptor value considers whether, for example, the receptor is rare, has protected or threatened status, has importance at a local, regional, national or international scale, and in the case of biological receptors whether the receptor has a key role in the ecosystem function.

50. The 'value' of a receptor forms an important element within the assessment, for instance, if the receptor is a protected species or has an economic value its value may be greater than otherwise.

51. It is important to understand that high value and sensitivity are not necessarily linked within a particular impact. A receptor could be of high value (e.g. an Annex II species), but have a low or negligible sensitivity to an effect. Similarly, low value does not equate to low sensitivity and is judged on a receptor by receptor basis. The value of the feature or receptor is a function of a range of factors (e.g. biodiversity value, social/community value and economic value).

52. Value will be considered, where relevant, as a modifier for the sensitivity assigned to the receptor, based on expert judgement. **Table 5-4** provides definitions for the value afforded to a receptor based on its legislative importance.

Table 5-4 Definitions of the Value Levels

Value	Definition
High	Internationally or nationally important. Internationally protected species that are listed as a qualifying interest feature of an internationally protected site (i.e. Annex II protected species designated feature of a European designated site) and protected species (including EPS) that are not qualifying features of a European designated site.
Medium	Regionally important or internationally rare. Protected species that are not qualifying features of a European designated site, but are recognised as a Biodiversity Action Plan (BAP) priority species either alone or under a grouped action plan, and are listed on the local action plan relating to the marine mammal study area.
Low	Locally important or nationally rare. Protected species that are not qualifying features of a European designated site and are occasionally recorded within the study area in low numbers compared to other regions.
Negligible	Not considered to be particularly important or rare Species that are not qualifying features of a European designated site and are never or infrequently recorded within the study area in very low numbers compared to other regions.

53. In addition to legislative factors, a range of other characteristics will be considered in the categorisation of importance, for example:

- Species or sub-species that are rare or uncommon, either internationally, nationally or more locally, including those that may be seasonally transient;
- Endemic species or locally distinct sub-populations of a species;
- Size of habitat or species population;

- Species in decline;
- Species rich assemblages;
- Large populations of species or concentrations of species considered uncommon or threatened in a wider context; and
- Species on the edge of their range, particularly where their distribution is changing as a result of global trends and climate change.

54. The value or potential value of a receptor or feature can be determined within a defined geographical context, for example, the following hierarchy to describe value is recommended by the Chartered Institute of Ecology and Environmental Management (CIEEM) (2016) with respect to ecological receptors:

- International and European;
- National;
- Regional;
- Metropolitan, County, vice-county or other local authority-wide area; and
- Local (e.g. assessment within a district or borough context or within a ‘zone of influence’).

55. Value is considered for each receptor, using available evidence including published data sources. The conclusions reached regarding the value of receptors have been presented in the baseline sections of each technical chapter (**Chapters 7 to 26**).

5.3.4.3.3. The Magnitude of Effect

56. In order to predict the significance of an impact, it is fundamental to establish the magnitude and probability of an impact occurring through a consideration of (CIEEM, 2018):

- Scale or spatial extent: the area over which an effect occurs (small scale to large scale or a few individuals to most of the population);
- Duration: the time for which the effect occurs (short term to long term);
- Likelihood of impact occurring;
- Frequency: how often the effect occurs;
- Nature of change relative to the baseline: positive or negative; and
- Reversibility: the degree of change relative to existing environmental conditions.

57. The categorisation of some of these elements is not always appropriate or required, and may rely on expert opinion.

58. The categorisation of duration for topics considered within this ES is presented in **Table 5-5**.

Table 5-5 Definitions of Temporal Scale of Magnitude

Temporal Scale	Definition
Permanent	Impacts continuing indefinitely beyond the span of one human generation (taken as approximately 25 years), except where there is likely to be substantial improvement after this period.
Long term	Approximately 15 - 25 years or longer (refer to above).
Medium term	Approximately 5 - 15 years.
Short term	Up to approximately 5 years.

59. In order to help define impact magnitude, the criteria presented in **Table 5-6** have been adopted for the purposes of this EIA. While **Table 5-6** provides guidelines of a generic nature, it should be noted that more specific guidelines in relation to impact magnitude have been adopted for topics (i.e. marine ornithology and marine mammals), where considered necessary.

Table 5-6 Generic Guidelines used in the Determination of Magnitude of Effect

Magnitude	Description
Very high	Loss of resource and/or integrity of the resource; severe damage to key characteristics, features or elements (adverse). Permanent / irreplaceable change, which is certain to occur. Large scale improvement of resource or attribute quality; extensive restoration or enhancement (beneficial).
High	Loss of resource, but not affecting integrity of the resource; partial loss of or damage to key characteristics, features or elements (adverse). Permanent / irreplaceable change, which is likely to occur. Improvement to, or addition of, key characteristics, features or elements of the resource; improvement of attribute quality (beneficial).
Medium	Minor loss of, or alteration to, one (maybe more) key characteristics, features or elements; measurable change in attributes, quality or vulnerability (adverse). Long-term though reversible change, which is likely to occur. Minor improvement to, or addition of, one (maybe more) key characteristics, features or elements of the resource; minor improvement to attribute quality (beneficial).
Low	Very minor loss of, or alteration to, one (maybe more) key characteristics, features or elements; noticeable change in attributes, quality or vulnerability (adverse). Short- to medium-term though reversible change, which could possibly occur. Very minor improvement to, or addition of, one (maybe more) key characteristic, feature or element; very minor improvement to attribute quality (beneficial).
Very low	Temporary or intermittent very minor loss of, or alteration to, one (maybe more) characteristic, feature or element; possible change in attributes, quality or vulnerability (adverse). Short-term, intermittent and reversible change, which is unlikely to occur. Possible very minor improvement to, or addition of, one (maybe more) characteristic, feature or element; possible improvement to attribute quality (beneficial).

5.3.4.3.4. Impact Significance

60. Subsequent to establishing the sensitivity and magnitude, the impact significance is predicted by using quantitative or qualitative criteria, as appropriate, to ensure a robust assessment. The significance of the potential impacts is assessed on the scale, degree or intensity of disturbance to the baseline conditions. Four levels of magnitude are used: high; medium; low; or negligible, as defined in **Table 5-6**.

61. Impact statements carry a degree of subjectivity, as they are based on expert judgement regarding the effect-receptor interaction that occurs and on available data. As such, impact statements should be qualified appropriately. Where possible the matrix presented in **Table 5-7** has been used to aid assessment of impact significance, combined with the application of expert judgement, to facilitate a consistent approach throughout the EIA. However, for each topic within the EIA, best practice methodology (based on the latest available guidance) has been followed and hence, when more appropriate, an alternative approach to the use of a matrix may be used.

62. By combining the magnitude of the impact and the sensitivity of the receptor in a matrix (see **Table 5-7**), the final significance of the impact (prior to the implementation of mitigation measures) can be obtained.

63. Definitions of impact significance are provided in **Table 5-8**. In the context of EIA, 'significant impacts' are taken to be those of moderate or major significance (as defined in **Table 5-8** below); albeit that appropriate mitigation, where available, should be sought for all impacts. Whilst minor impacts would not be deemed to be significant in their own right, they may contribute to significant impacts through inter-relationships or cumulative impacts.

Table 5-7 Impact Assessment Matrix

		Negative Magnitude				Beneficial Magnitude			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

Table 5-8 Impact Significance Definitions

Value	Definition
Major	Very large or large change in receptor, either adverse or beneficial, which are important at a population (national or international) level because they contribute to achieving national or regional objectives, or, expected to result in exceedance of statutory objectives and / or breaches of legislation.
Moderate	Intermediate or large change in receptor, which may to be important considerations at national or regional population level. Potential to result in exceedance of statutory objectives and / or breaches of legislation.
Minor	Small change in receptor, which may be raised as local issues but are unlikely to be important at a regional population level.
Negligible	No discernible change in receptor.

64. It should be noted that any residual impact (the impact after the implementation of mitigation; see **Section 5.3.4.6** below) which remains at the level of 'moderate' or 'major' is regarded by the EIA Regulations as being significant.

65. It should also be reiterated that, although this section sets out the overall approach adopted for this EIA, individual chapters may take their own approach where industry standard methodologies are appropriate or another approach has been agreed with the relevant regulator. Where a different approach is taken, this is explained in the relevant methodology section.

5.3.4.4. Confidence

66. Once an assessment of a potential impact has been made, it is necessary to assign a confidence value to the assessment to assist in the understanding of the judgement. This is undertaken on a simple scale of high-medium-low, where high confidence assessments are made on the basis of robust evidence, with lower confidence assessments being based, for example, on extrapolation and use of proxies.

5.3.4.5. Mitigation Measures

67. Where an impact assessment identifies that an aspect of the Project is likely to give rise to significant environmental impacts, mitigation measures have been proposed, in order to avoid impacts or reduce them to acceptable levels.

68. For the purposes of the EIA, two types of mitigation have been defined:

- Embedded mitigation: mitigation measures that are identified and adopted as part of the evolution of the project design, and are included and assessed in the EIA; and
- Additional mitigation: mitigation measures that are identified during the EIA process specifically to reduce or eliminate any predicted significant impacts.

69. It is important to note that the mitigation measures applied should be proportionate to the scale of the impact predicted. Appropriate mitigation measures have been discussed and agreed, where possible, with the relevant regulatory authorities and stakeholders. Whilst mitigation for minor or negligible impacts may not be specifically defined as a matter of course, industry standard or 'embedded' mitigation often applies in these cases (and is set out herein). It is also recognised that minor and negligible impacts could become significant when considered cumulatively with other pressures on a receptor and, in this event, mitigation may be required.

70. All mitigation associated with the Project is identified and described in more detail in the relevant chapters of the ES (**Chapters 7 to 26**).

5.3.4.6. Residual Impacts

71. Where further mitigation measures are identified, the significance of the residual environmental impact (i.e. the post-mitigation impact) has been re-assessed and residual impacts described.

72. Where no mitigation measure is proposed, a discussion explains why the impact cannot be reduced.

5.3.4.7. Monitoring

73. Appropriate mitigation measures have been identified and recommended in this ES where the EIA process has identified an adverse impact and mitigation is available (see **Section 5.3.4.5** above). In some cases, in order to ensure that the mitigation measures are successful or where there is significant uncertainty with respect to important receptors, monitoring may be appropriate.

74. Monitoring programmes are most commonly required during and shortly after construction, but can also be prior to and during operations. The nature of any monitoring is dependent on the nature of the effect or mitigation measure under inspection and is discussed within the relevant chapters of the ES (**Chapters 7 to 26**). An Outline Construction Environment Management Plan (**Document MOR/RHDHV/DOC/0073**) and Outline Environment Mitigation and Monitoring Plan (**Document MOR/RHDHV/DOC/0072**) are also provided in support of the TWAO and Marine Licence applications for the Project.

5.3.5. Cumulative Impact Assessment

5.3.5.1. Impact Inter-Relationships

75. Council Directive 2011/92/EU on the assessment of the effects of certain public and private projects on the environment (the EIA Directive) states (in Annex III) that an ES should include "*A description of the aspects of the environment likely to be significantly affected by the proposed project, including, in particular, population, fauna, flora, soil, water, air, climatic factors, material assets, including the architectural and archaeological heritage, landscape and the inter-relationship between the above factors*".

76. This ES has given due consideration to the potential for different residual impacts to have a combined impact on key sensitive receptors. For example, a landscape and visual effect and noise impact may cumulatively impact on a receptor.

77. The objective is to identify where the accumulation of impacts on a single receptor, and the relationship between those impacts, potentially gives rise to a need for additional mitigation.

78. Inter-relationships have been assessed within the relevant sections of the topic chapters of the ES.

5.3.5.2. Cumulative Impacts

79. Cumulative Impact Assessment (CIA) is undertaken as part of each technical chapter impact assessment. In line with IEMA's Guidelines for EIA (2004), cumulative impacts are defined as: "…the impacts on the environment which result from incremental impacts of the action when added to other past, present and reasonably foreseeable future actions …".

80. There is no legislation that outlines how CIAs should be undertaken. However, the EIA and Habitats Directives and their associated regulations require the consideration of direct impacts and any indirect, secondary and cumulative effects of a project. Schedule 4, of Regulation 17 (3), of the Town and Country Planning (Environmental Impact Assessment) (Wales) Regulations 2017 states that the CIA should consider: "*the cumulation of effects with other existing and/or approved projects, taking into account any existing environmental problems relating to areas of particular environmental importance likely to be affected or the use of natural resources*".

81. Guidance on cumulative effects assessment is provided in a number of good practice documents (e.g. RenewableUK, 2013). This guidance is not prescriptive, but rather suggests various approaches which may be used, depending on their suitability to the Project (for example the use of matrices, expert opinion, consultation, spatial analysis and carrying capacity analysis).

82. A tiered approach has been adopted for the Project, based upon the following definitions:

- Site-specific (or within-development) cumulative impacts - different effects associated with the proposed scheme have the potential to interact and, together, influence common receptors. Where applicable, these inter-relationships are considered in the ES and HRA.
- Wider cumulative impacts which are the combined impacts (additive or interactive) that may occur between the proposed facilities, and any other relevant development(s) for which information is publicly available.

83. With respect to 'past' projects, a useful ground rule in CIA is that the environmental impacts of schemes that have been completed should be included within the environmental baseline; as such, these impacts will be taken into account in the EIA process and, generally, can be excluded from the scope of CIA. Where projects are already in existence they are therefore deemed to be part of the existing environment, contributing to the baseline conditions and are therefore not considered to provide a further cumulative impact. However, the environmental impacts of recently completed projects may not be fully manifested and, therefore, the potential impacts of such projects should be taken into account in the CIA.

84. The study area for the CIA varies depending on the range and characteristics of the receptor as well as the extent of impacts associated with the Project and therefore each technical chapter provides information on the relevant foreseeable projects for consideration in the CIA.

5.3.5.3. Assumptions and Limitations

85. The EIA process also requires that an ES is prepared by competent experts. This ES has been compiled by Royal HaskoningDHV and MarineSpace. Royal HaskoningDHV is the UK's leading EIA consultant, successfully leading the EIA and consent process for over 10GW of UK offshore wind projects, including six successful DCO applications, as well as successfully completing the EIA and consenting three significant tidal stream projects, the world's first commercial tidal turbine deployment (SeaGen), the world's first tidal array (Sound of Islay) and the world's first commercial demonstration project (PTEC). MarineSpace is a specialist marine consultancy and has supported a range of projects including providing consultancy support to Tidal Energy Limited (TEL) on its Ramsey and St David's Head projects and consenting support to Tidal Lagoon Power Ltd (TLP) in developing the Adaptive Environmental Management Plan (AEMP) for the Swansea Bay Tidal Lagoon project.

86. Royal HaskoningDHV is a corporate member of the Institute of Environmental Management & Assessment (IEMA) (number 0001189) and also a Corporate Registered Assessor for EIA under IEMA's voluntary EIA Quality Mark scheme, through which EIA activity is independently reviewed, on an annual basis, to ensure it delivers excellence in areas including EIA management, team capabilities, regulatory compliance, content, presentation, and improving practice.

87. All Royal HaskoningDHV's lead authors are senior and chartered professionals with a significant track record in undertaking technical assessment and EIA in their discipline. The team undertaking the EIA for the Project is comprised of a dedicated core team of EIA professionals who take the lead role in the co-ordination and management of the EIA and the preparation of

the ES. The core team is then supported by a wider team of technical specialists taking responsibility of the data collection, data analysis and technical impact assessment.

88. Some of the technical assessment and associated ES chapters are undertaken by specialist consultancies outside Royal HaskoningDHV. These include Shipping and Navigation, Landscape and Visual and Socio-economics. All specialist consultants have been selected by Menter Môn based on stringent quality checks.

89. The EIA process requires an ES to provide an indication of any difficulties (technical deficiencies or lack of know-how) encountered during the assessment process. Any such assumptions or limitations are identified within the relevant topic chapter, where relevant.

90. The information provided by third parties, including publicly available information and databases, is correct at the time of publication. The EIA has been subject to the following limitations:

- Existing environmental conditions have been assumed to be accurate at the time of the physical surveys; however, due to the dynamic nature of the environment, conditions may change during the various phases of the development; and
- The assessment of cumulative impacts has been reliant on the availability of accurate information on the proposed developments that may act in combination with the one outlined within this ES.

5.4. SUMMARY

91. This chapter outlines the approach that has been used to frame and present the expert judgements used in assessing the potential impacts during the construction, operation and decommissioning of the Project.

92. For each topic of the EIA, the most relevant and latest guidance and/or best practice has been used. Therefore, where appropriate, the approach to each impact assessment (including definitions of sensitivity and magnitude of impact) is tailored to each receptor as detailed in **Chapters 7 to 26**.

GLOSSARY OF ABBREVIATIONS

CRM	Collision Risk Model
DCO	Development Consent Order
EIA	Environmental Impact Assessment
ERM	Encounter Rate Model
ES	Environmental Statement
FEED	Front End Engineering Design
FLO	Fisheries Liaison Officer
GAFLAG	Gwynedd and Anglesey Fisheries Local Action Group
GAPS	Gwynedd Archaeological Planning Service
HRA	Habitats Regulations Assessment
IFCA	Association of Inshore Fisheries and Conservation Authorities
IoACC	Isle of Anglesey County Council
MCA	Maritime and Coastguard Agency
MMO	Marine Management Organisation
MoD	Ministry of Defence
NGO	Non-Governmental Organisation
NRA	Navigation Risk Assessment
NRW	Natural Resources Wales
NWFCL	North Wales Fishermen's Co-operative Limited
ODA	Onshore Development Area
PHA	Preliminary Hazard Analysis
PID	Public Information Day
PINS	Planning Inspectorate
PR	Public Relations
PVA	Population Viability Analysis
RCAHMW	Royal Commission on the Ancient and Historical Monuments of Wales
RNLI	Royal National Lifeboat Institution
RSPB	Royal Society for the Protection of Birds
RYA	Royal Yachting Association
SAC	Special Area of Conservation
SLVIA	Seascape, Landscape and Visual Impact Assessment
SMRU	Sea Mammal Research Unit
SNCB	Statutory Nature Conservation Body
SoCG	Statement of Common Ground
SSSI	Site of Special Scientific Interest
TWAO	Transport and Works Act Order
TWG	Technical Working Group
UK	United Kingdom
WEFO	Welsh European Funding Office

WFA	Welsh Fishermen's Association
ZTV	Zone of Theoretical Visibility

6. CONSULTATION

6.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) presents and summarises the project wide consultation undertaken relating to the Environmental Impact Assessment (EIA) for the Morlais Project (the Project). Within each technical chapter, all specific, relevant stakeholder consultations are also presented in further detail.

2. Menter Môn has developed a Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**) which sets out the pre-application engagement and consultation undertaken in relation to the Project, including statutory and non-statutory interests. The ES and Consultation Report will accompany the Transport and Works Act Order (TWAO) and Marine Licence applications.

6.2. POLICY AND LEGISLATION

3. The Transport and Works (Applications and Objections Procedure) (England and Wales) Rules 2006 specifically required that the TWAO application be accompanied by "*a report summarising the consultations that have been undertaken, including confirmation that the applicant has consulted all those named in column (2) of the tables in Schedules 5 and 6 to these Rules where authority is sought for works or other matters described in column (1) of those tables*".

4. Consultation in relation to the EIA must also include statutory consultation (i.e. scoping and consultation undertaken in accordance with the Town and Country Planning (Environmental Impact Assessment) (Wales) Regulations 2017, and the Marine Works (Environmental Impact Assessment) (Amendment) Regulations 2017 (herein collectively known as 'the EIA Regulations'), and non-statutory consultation (i.e. consultation not required by the Regulations but undertaken to support the EIA process). Non-statutory consultation includes further engagement with relevant statutory bodies, and engagement/consultation with other organisations that have a relevant science-based interest.

5. Schedules 5 and 6 of the Procedure Rules primarily relate to the consultation required once the application has been made; however, Menter Môn has chosen to front-load engagement and consultation to maintain open engagement with the public, statutory consultees and other stakeholders throughout the pre-application process in order to optimise communications and information sharing, and to inform the EIA process.

   Drawing upon experience of other consenting regimes that have procedures to obligate developers to undertake pre-application engagement and consultation, such as the Development Consent Order (DCO) process under the Planning Act 2008, Menter Môn applied a technical working group and "statement of common ground" approach to management of selected key environmental issues for the EIA process, in particular with respect of the TWAO application, but also in support of wider EIA consultation requirements and the Marine Licence.

6.3. GENERAL APPROACH TO CONSULTATION

6. Menter Môn recognises that effective and meaningful consultation is an integral part of its development activities and is committed to ensuring an open and transparent approach to engagement and consultation with stakeholders.

7. Early engagement of local communities, local authorities and statutory consultees aims to bring about the following shared benefits:

- To allow the public to influence how the Project is developed and how it is integrated in the community by providing the Morlais development team with feedback on potential options;
- To help local people and stakeholders understand better what the Project means for them;
- To obtain important information about the economic, social and environmental impacts of the Project – helping Morlais to identify unsuitable Project options as early as possible;
- To enable potential mitigating measures to be considered and, where appropriate, built into the Project before the application is submitted; and
- To identify new ways in which the Project could support wider strategic and/or local objectives.

8. Public engagement and consultation was undertaken to engage with user groups, communities and individuals potentially affected by the Project. These groups were provided with Project details, an explanation of the EIA process and an overview of studies and surveys being undertaken. This process provided the framework for expression of opinions, information sharing and stakeholder feedback. A summary of public engagement and consultation is set out in the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

9. The purpose of early EIA stakeholder consultation on the Project is to enable discussion of the proposals and potential impacts with stakeholders and to seek feedback so that comments can inform proposals, including the EIA and Front End Engineering Design (FEED) process.

6.4. APPROACH TO EIA CONSULTATION

6.4.1. Background

10. Two scoping reports were previously submitted to Natural Resources Wales (NRW), the Marine Management Organisation (MMO) and the Isle of Anglesey County Council (IoACC) in support of earlier (lower capacity) versions of the Project. However, the proposed installed capacity of the Project has since been increased and the Project is now seeking consent for up to 240 MW capacity. A further request for scoping opinion was therefore submitted to the Welsh Government and NRW in April 2018, which supersedes the earlier scoping reports.

11. The Welsh Government and NRW provided a detailed scoping opinion, which has been the starting point for consultation on the Project. Consultation with the Welsh Government and NRW has been ongoing throughout the EIA to discuss developments in the Project, scope and design

parameters, and to agree methodologies and approaches used for environmental surveys and assessments during the EIA process.

12. Royal HaskoningDHV and MarineSpace have led consultation with statutory consultees and regulators for the TWAO and the Marine Licence during the EIA process. Statutory consultation has been undertaken, with focus on Welsh Government – Planning Section; NRW; and IoACC. In addition, although not a statutory body, the Royal Society for the Protection of Birds (RSPB) as a key landowner has been included in consultation undertaken by Royal HaskoningDHV and MarineSpace.

13. Royal HaskoningDHV and MarineSpace led all technical EIA consultation, including leading on communications with Cadw, IoACC, NRW (in its capacity as a Statutory Nature Conservation Body (SNCB)) and RSPB, as well as fisheries stakeholders. Although not required as statutory documents under Schedule 5 and 6 of the Transport and Works (Applications and Objections Procedure) (England and Wales) Rules 2006, Menter Môn is submitting Statements of Common Ground (SoCG) on key technical issues; marine mammals, marine ornithology and seascape, landscape and visual impact assessment (SLVIA).

14. Royal HaskoningDHV also led on consultation with the following non-statutory conservation stakeholders: North Wales Wildlife Trust; Gwynedd Archaeological Trust; UK Whale and Dolphin Conservation Trust; and Marine Conservation Society.

15. Navigation and shipping consultation, including recreational interests, was led by the Navigation Risk Assessment (NRA) Consultants, Marico Marine, with review by RHDHV and MarineSpace.

16. Community engagement and other non-statutory consultation was undertaken by Menter Môn with support from the appointed Public Relations (PR) Company, Ateb. The focus of this engagement and consultation was to increase awareness of the Project, share information and invite comments. In addition to promoting the Project and sharing information on the proposals, two series of public information days (PIDs) were held. Further information on community engagement and other non-statutory consultation is included within the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

6.4.2. EIA Scoping Opinion

17. Scoping responses were received from NRW and the Welsh Government and have been taken into account within the EIA (**Chapters 7** to **26**). Direct responses to the Welsh Government as part of this process were received from Cadw, MMO and NRW, in its capacity as a SNCB. The formal scoping responses from NRW and the Welsh Government are provided in **Appendix 6.1** (**Volume III**).

18. Following receipt of the Scoping Opinion, Menter Môn undertook a series of preliminary meetings to discuss the Project further with key EIA stakeholders.

19. Menter Môn has reviewed consultation responses received and in light of the feedback, has made a number of key decisions in relation to the project design and site selection which are outlined in **Chapter 2, Project Description** and **Chapter 3, Site Selection and Consideration of Alternatives**, respectively.

6.4.3. Technical Working Groups and Statements of Common Ground

6.4.3.1. Technical Working Groups

20. Menter Môn also assembled Technical Working Groups (TWG) to discuss key topic areas. TWGs are a way to discuss the methods used for data collections and analysis, use of the data itself, assessment methods, and results. These can then be brought to bear on mitigation and management of impacts, and in particular adaptive management approaches which may be adopted to address impact pathway or receptor sensitivity or receptor vulnerability unknowns. The aim is to undertake a process of review, discussion and where possible, agreement, in a 'face to face' environment where the aim is to air and resolve disagreements or agree approaches which will allow this to be achieved.

21. Three TWGs were established to enable technical discussions with experts from relevant stakeholders, as follows:

- Marine Mammals;
- Ornithology; and
- SLVIA.

22. The main participants of the TWGs were technical experts mainly drawn from NRW and, for landscape matters, from IoACC. Three meetings were held for each TWG pre-application (**Table 6-1**). The groups may meet post application as appropriate and as directed by the regulator to resolve remaining issues. A clear agenda was agreed for each meeting detailing the issues to be discussed, the questions set out to answer and the aim of the process.

Table 6-1 Technical Working Group Meeting Details

Topic	Date	Attendees	Agenda

Marine Mammals First TWG Meeting	27th November 2018	NRW, Menter Môn, Royal HaskoningDHV	▪ Project background (recap)
			▪ Review of project design envelope
			▪ Species, density estimates, reference populations and management units
			  ▪ Scale of assessment
			▪ Approach to Collision Risk Model (CRM)/Encounter Rate Model (ERM)
			  ▪ Species parameters and dive profiles
			  ▪ Appropriate avoidance rates
			▪ Use of population modelling
			  ▪ iPCoD
			▪ Approach to assessment / potential impacts
			▪ Cumulative assessment
			▪ Phased deployment

Marine Mammals Second TWG Meeting	19th February 2019	NRW, Menter Môn, Royal HaskoningDHV	▪ Overview of tidal device design envelope ▪ Tidal device parameters ▪ Collision risk models: ERM and CRM ▪ Environmental parameters: water depth and current speed

Topic	Date	Attendees	Agenda
			▪ Marine mammal species: density estimates and reference populations ▪ Marine mammal parameters: body length and width; dive profiles and parameters ▪ Avoidance rates
Marine Mammals Third TWG Meeting	10th May 2019	NRW, Menter Môn, Royal HaskoningDHV	▪ Summary of density estimates and reference populations for species and Special Areas of Conservation (SACs) used in the assessments. ▪ Overview of assessments for ES and Habitats Regulations Assessment (HRA), including underwater noise, disturbance, barrier effects, changes in prey / habitat loss and collision risk. ▪ PCoD – update. ▪ Proposed approach to monitoring and mitigation.

Ornithology First TWG Meeting	13th December 2018	NRW, Menter Môn, Royal HaskoningDHV	▪ Project background (recap)
			▪ Review of project design envelope
			▪ Species, conservation sites and populations to be included
			▪ Appropriate spatial scale for assessment
			▪ Review species parameters and vulnerability by species/group:
			  ▪ Above water
			  ▪ Submerged
			  ▪ Foraging distances
			▪ Approach to CRM/ERM
			  ▪ Appropriate avoidance rates
			▪ Potential Biological Removal
			▪ Approach to assessment / potential impacts
			▪ Cumulative assessment
			▪ Summary

Ornithology Second TWG Meeting	19th February 2019	NRW, Menter Môn, Royal HaskoningDHV	▪ Overview of CRM and ERM: ▪ Methods, limitations, interpretation, role in EIA ▪ Device parameters and overview of modelling scenarios ▪ Bird input parameters (densities and diving behaviour) and sources of information ▪ Avoidance rates: what might be appropriate and why? ▪ Presentation and review of preliminary results ▪ Plans for future work

Topic	Date	Attendees	Agenda
			▪ Obtaining feedback on work already undertaken and planned
Ornithology Third TWG Meeting	3rd May 2019	NRW, Menter Môn, Royal HaskoningDHV	▪ Outstanding points and queries raised in first and second TWG meetings ▪ Progress update on Marine Ornithology EIA, including ERM/CRM and Population Viability Analysis (PVA) for Holy Island Coast Site of Special Scientific Interest (SSSI) ▪ Progress update on Marine Ornithology HRA ▪ Progress update on Terrestrial Ornithology EIA - chough

SLVIA First TWG Meeting	30th October 2018	NRW, IoACC, Menter Môn, Royal HaskoningDHV	▪ Project background (recap)
			▪ Review of Project Design Envelope
			▪ Baseline data collection
			▪ Assessment methodology
			▪ Night time lighting assessment
			▪ Offshore Zone of Theoretical Visibility (ZTV) parameters and proposed viewpoints
			▪ Onshore ZTV parameters (including proposed viewpoints)
			    ▪ Grid connection substation
			    ▪ Landfall substation
			▪ Cumulative assessment

SLVIA Second TWG Meeting	12th March 2019	NRW, IoACC, Menter Môn, Royal HaskoningDHV	▪ Project background (recap) ▪ Review of Project Design Envelope ▪ Offshore Project Design Envelope: Draft Layout ▪ Draft Visualisations ▪ Viewpoint assessment (update) ▪ Night time lighting assessment (update) ▪ Navigation Lighting update ▪ Onshore Design Review ▪ Landfall substation ▪ Grid connection substation ▪ Mitigation – colour guide
SLVIA Third TWG Meeting	17th April 2019	NRW, IoACC, Menter Môn, Royal HaskoningDHV	▪ Review of Project Design Envelope (offshore elements) ▪ Mitigated design envelope - careful consideration of NRW/IACC comments ▪ Draft visualisations ▪ Assessment scope update (viewpoint selection and night time photography) ▪ Landfall substation ▪ Scheme design work undertaken following second TWG

Topic	Date	Attendees	Agenda
			▪ Draft visualisations ▪ Assessment scope considerations (viewpoint selection) ▪ Grid substations ▪ Scheme proposals ▪ Assessment scope considerations (viewpoint selection)

6.4.3.2. Statements of Common Ground

23. The main mechanism for capturing the works undertaken and agreed positions reached within each of the TWGs is through the development of SoCG: living documents that capture the work, and agreed positions achieved by each group. Menter Môn has endeavoured to agree SoCG on key technical issues relating to those topic areas in order to aid the Welsh Government and NRW in understanding where there is substantial agreement with stakeholders and where additional management measures and mitigation may be required.

24. The SoCG were developed over the course of the consenting programme as follows:

- A series of TWG meetings were held with the key parties relevant to the issue under discussion, in most instances this was the NRW technical experts, with the IoACC as appropriate (**Table 6-1**);
- A record was kept of the TWG meetings through meeting minutes. The meeting minutes detail the key questions discussed, areas of disagreement and areas of agreement;
- The meeting minutes allow each meeting to build upon the previous discussions sequentially and provide the source material for the SoCG, a report detailing the status of the discussions held, including the areas of agreement and of disagreement.

25. The SoCGs have been used to support the assessment undertaken during the EIA and will form the basis of any post application discussions required by the regulator, from a continuation of technical meetings through to potential preparation for a public inquiry.

26. The purpose of the SoCGs is to demonstrate the process followed to support the application, the agreement reached between parties and where disagreement still lies. They will support the inquiry stage of the consent process and demonstrate to the inspector the measures taken to reach application.

27. SoCGs have been produced for Marine Mammals (**Appendix 6.2, Volume III**), Marine Ornithology (**Appendix 6.3, Volume III**) and SLVIA (**Appendix 6.4, Volume III**). It should be noted that the SoCGs are live documents and will be updated following the continuation of TWGs post application, where required.

6.4.4. Other Consultation Meetings on TWAO and Marine Licence Applications

6.4.4.1. Commercial Fisheries

28. MarineSpace led this aspect of consultation on behalf of RHDHV, in liaison with Menter Môn and Ateb. The focus of consultation was on relevant organisations and vessel operators, including:

- Welsh Fishermen's Association (WFA);
- North Wales Fishermen's Co-operative Limited (NWFCL);
- Gwynedd and Anglesey Fisheries Local Action Group (GAFLAG); and
- Anglesey vessel owners and relevant operators operating locally to the project site.

29. Information was gathered on the following aspects of fisheries use of the Project area:

- Current and historical fishing activity;
- Spatial patterns of fishing activity;
- Temporal patterns of fishing activity;
- Relative importance and economics of fishing grounds;
- Onward market chain;
- Potential opportunities to provide support to the Project (supply chain); and
- Concerns and perceptions about the Project.

30. A summary of the above consultation is provided in **Table 6-2**.

6.4.4.2. Shipping and Navigation

31. Menter Môn's appointed Shipping and Navigation Risk consultants, Marico Marine, mapped navigation stakeholders and statutory consultees during the production of a Preliminary Hazard Analysis (PHA). Marico Marine met with the MCA to discuss the project and obtain their feedback on the proposed scope of work for the NRA, to ensure all potential issues are covered. The PHA report was issued to relevant navigational stakeholders for comment.

32. Winter and summer (14 day) marine traffic surveys were undertaken in 2017 and the collected data were used in the development of a NRA (**Appendix 15.1, Volume III**). A third winter survey was undertaken in April 2019 and informed the NRA. As part of the NRA, Marico Marine met with key shipping and navigational stakeholders. Meetings with the following organisations or their representatives were held during this process:

- Maritime and Coastguard Agency (MCA);
- Chamber of Shipping;
- Trinity House;
- WFA;
- Holyhead Harbour Master;

- Royal Yachting Association (RYA);
- Royal National Lifeboat Institution (RNLI);
- Irish Ferries;
- Stena Line; and
- Local Recreational Clubs.

33. The same stakeholders were invited to participate in the Hazard Review Workshop, where hazards and associated impacts are identified and reviewed.

34. A summary of the above consultation is provided in **Table 6-2**.

6.4.4.3. Ministry of Defence

35. Consultation has also been undertaken with the Ministry of Defence (MoD) to understand the previous and/or current use of the site and any potential issues. The aim of this consultation was to confirm that there is no actual use of these areas or identify significant issues and agree solutions/mitigation as appropriate.

36. This consultation was carried out via the EIA Scoping process, with the MoD being issued the various versions of the EIA Scoping Report between 2015 and 2018. Responses were received from the MoD and incorporated into the EIA process.

6.4.4.4. Environmental Interest Groups and Non-Governmental Organisations (NGOs)

37. Environmental groups have been contacted by email or telephone, providing a brief overview of the project and the timescales for the application. The Consultation Report also provides details of those groups invited to PIDs for the Project (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

38. Feedback from each group at the PIDs is incorporated into the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**) and used in the relevant receptor impact assessments, as well as being outlined in the ES.

6.4.4.5. Public Engagement

39. Menter Môn has engaged with a diverse range of stakeholders and user groups regarding the proposed Project through a number of processes since 2015.

40. During the pre-application stage, Menter Môn engaged with relevant local authorities, landowners, community councils and other local stakeholders, in order to raise awareness of the Project, the proposals, to outline the consenting process and to highlight opportunities to input. The process of engagement and consultation with the community and other stakeholders is set out in the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

41. Menter Môn undertook engagement with local communities and user groups with support from Ateb, RHDHV and MarineSpace. Local communities and user groups identified for consultation were as follows:

- Community and Town Councils within/adjacent to the Project area;
- Local business owners;
- Tourism sector contacts; and
- Recreational groups (sailing, diving and recreational fishing).

42. The key elements of consultation undertaken are as follows:

- Drop in exhibitions held at locations within and adjacent to the Onshore Development Area, at which project information was made be available, and the project team was available to meet the public, answer questions, and discuss the project;
  - First PID held on the 19th March 2019; and
  - Second PID held over three sessions on 11th, 12th and 17th June 2019.
- Community engagement events and briefings with Community and Town Councillors;
- Recreation group meetings as appropriate;
- Newsletters distributed throughout the onshore project area. These newsletters were distributed prior to each PID event; in March and June;
- Leafleting relevant communities to ‘capture’ hard to reach groups; and
- Provision of a dedicated project website; and
- Publicity and awareness raising though media outlets, with focus on printed press, but potentially including radio and television if opportunities present.

43. Further information is set out in the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**)

6.4.4.6. Landowner Engagement

44. Consultation has been undertaken directly with landowners and interested parties including tenants, occupiers and other parties with land rights. Engagement with individual land owners within or adjacent to the proposed development was managed directly by Menter Môn, with support from their appointed Land Agent.

45. Menter Môn has engaged with landowners regarding survey access, through consultation meetings and during the land referencing process. Letters were sent to all potentially affected parties offering to meet to discuss the project proposals.

46. In addition, Menter Môn’s land agents have contacted the affected landowners. A number of onshore cable route change suggestions have been put forward by those affected by the onshore development area (ODA). Menter Môn have been able to incorporate a number of those suggestions into the final design of the Project.

47. Further information on these discussions have been considered within **Chapter 3, Site Selection and Consideration of Alternatives** where relevant and the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

6.4.5. Summary of EIA Consultation

48. A summary of the statutory and non-statutory consultation undertaken for the Project is provided in **Table 6-2.** Note that the RSPB and SEACAMS are included here although their roles are not statutory, because of their science-based approach and availability of data to support the EIA process. A full list of non-statutory communication undertaken, such as with recreational groups, is presented within the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

49. In addition to the consultation activities presented below, Menter Môn met with the Planning Inspectorate and IoACC's Planning Officer on a regular basis throughout the development of the Project, to provide updates and to seek advice on subjects including the site selection process, approach to the EIA and drafting the application documents.

Table 6-2 Overview of Statutory and Non-Statutory Consultation Made to Date

Date	Consultee	Topic	Format	Content	Considerations to ES
24/08/2015	SEACAMS	Marine Mammals	Meeting	Introduction to Project and view on mammal data requirements for consent.	Feedback built into the EIA approach for **Chapter 12, Marine Mammals**.
24/05/2016	NRW	Project Introduction / Update	Meeting	Discussion of planning performance agreement and Project timescales.	Informed consenting strategy discussions for production of 2017 scoping report.
16/06/2016	Sea Mammal Research Unit (SMRU) & NRW	Project Design Envelope	Meeting	Project Design Envelope.	Feedback built into the 2017 Scoping Report.
17/06/2016	RSPB	Ornithology	Meeting	Project introduction, overview and status, RSPB local interest and concerns.	Feedback built into the EIA approach for **Chapter 11, Marine Ornithology**.
28/07/2016	SEACAMS & NRW	Marine Mammals	Meeting	Discussion around marine mammal survey data.	Feedback built into the EIA approach for **Chapter 12, Marine Mammals**.
24/05/2017	NRW	Project Introduction / Update	Meeting	Project update, summary of survey work undertaken to date.	No substantive feedback.
26/05/2017	RSPB	Ornithology	Meeting	Project update, summary of survey work undertaken to date.	No substantive feedback.
29/09/2017	NRW	Ornithology	Meeting	Update on progress with bird surveys, discussion regarding further survey effort.	Feedback built into the EIA approach for **Chapter 11, Marine Ornithology**.

Date	Consultee	Topic	Format	Content	Considerations to ES
13/12/2017	RSPB	Ornithology	Meeting	Update on progress with bird surveys.	Feedback built into the EIA approach for **Chapter 11, Marine Ornithology**.
09/01/2018	NRW	Consenting Strategy	Meeting	Project and consenting strategy update.	Informed consenting strategy decisions and requirements for submission of 2018 Scoping Report under DCO process.
17/01/2018	NRW & Welsh Government	Consenting Strategy	Meeting	Project update / discussion around consenting strategy.	Informed consenting strategy decisions and requirements for submission of 2018 Scoping Report under DCO process.
19/01/2018	Welsh European Funding Office (WEFO) & Welsh Government	Consenting Strategy	Meeting	Project update / discussion around consenting strategy.	Informed consenting strategy decisions and requirements for submission of 2018 Scoping Report under DCO process.
24/01/2018	RSPB	Ornithology	Meeting	Project Update.	No substantive feedback.
13/02/2018	IoACC	Onshore Ecology	Meeting	Discussion regarding the draft scope of works for the Extended Phase 1 Habitat Survey and proposed approach to Phase 2 surveys.	Feedback built into the EIA approach for **Chapter 19, Onshore Ecology**.
13/03/2018	IoACC	Onshore Ecology	Meeting	Discussion regarding the draft ecological survey methodology.	Feedback built into the EIA approach for **Chapter 19, Onshore Ecology**.
15/03/2018	Planning Inspectorate (PINS) & Welsh Government	Consenting Strategy	Meeting	Project inception meeting.	WG highlighted that if the DCO application was not accepted before the 1 April 2019, any Screening or Scoping Opinion issued by the Secretary of State would not carry any legal weight and the process would need to be carried out (in whole or in part) afresh by WG on behalf of the Welsh Ministers. WG advised that it would be possible for the Applicant to seek consent using a Transport and Works Act Order. This informed the consenting strategy of the Project.

12/06/2019	NRW	Marine Mammals	Information Request	Draft Marine Mammals SoCG sent to NRW for comment.	Feedback checked against **Chapter 12, Marine Mammals**.
18/06/2019	Network Rail	Traffic and Transport	Meeting	Project rail crossing options.	Discussions informed FEED and project design envelope (**Chapter 3, Site Selection and Consideration of Alternatives** and **Chapter 4, Project Description**).
04/07/19	IoACC	Traffic and Transport	Meeting	Provided a summary of the findings of the traffic and transport assessment.	No substantive feedback.

6.5. CONCLUSIONS

50. Menter Môn conducted a comprehensive and transparent pre-application consultation in relation to the EIA process, with a wide range of stakeholders. The aim of the consultation process was to meet and exceed the requirements of the TWA 1992 and EIA Regulations. To this end it has taken into account relevant advice and guidance published by the Planning Inspectorate, Welsh Government and relevant United Kingdom (UK) Government departments.

51. EIA stakeholders have been engaged in the development process from an early stage. Menter Môn acknowledge and appreciate their involvement and corresponding influence on the design of the Project (as outlined in **Chapter 3, Site Selection and Consideration of Alternatives**) and the EIA.

52. Consultation responses have been carefully documented and considered in the ongoing project development work. Responses which are considered relevant to this ES and the regard Menter Môn has had to them are included in each technical chapter of the ES and in the Consultation Report (**Document MOR/RHDHV/DOC/0066, Consultation Report**).

WNMP	Welsh National Marine Plan

GLOSSARY OF TERMINOLOGY

Astronomical tide	The predicted tide levels and character that would result from the gravitational effects of the earth, sun and moon without any atmospheric influences
Bathymetry	Topography of the sea bed
Beach	A deposit of non-cohesive sediment (e.g. sand, gravel) situated on the interface between dry land and the sea (or other large expanse of water) and actively ‘worked’ by present-day hydrodynamic processes (i.e. waves, tides and currents) and sometimes by winds

Bedforms	Features on the seabed (e.g. sand waves, ripples) resulting from the movement of sediment over it
Bedforms	Features on the seabed (e.g. sand waves, ripples) resulting from the movement of sediment over it
Climate change	A change in global or regional climate patterns. Within this chapter this usually relates to any long-term trend in mean sea level, wave height, wind speed etc, due to climate change
Closure depth	The depth that represents the 'seaward limit of significant depth change', but is not an absolute boundary across which there is no cross-shore sediment transport
Coastal processes	Collective term covering the action of natural forces on the shoreline and nearshore seabed
Crest	Highest point on a bedform or wave
Current	Flow of water generated by a variety of forcing mechanisms (e.g. waves, tides, wind)
Ebb tide	The falling tide, immediately following the period of high water and preceding the period of low water
Erosion	Wearing away of the land or seabed by natural forces (e.g. wind, waves, currents, chemical weathering)
Flood tide	The rising tide, immediately following the period of low water and preceding the period of high water
Glacial diamicton	Poorly sorted or non-sorted sediments of glacial origin
Gravel	Loose, rounded fragments of rock larger than sand but smaller than cobbles. Sediment larger than 2mm (as classified by the Wentworth scale used in sedimentology)
Habitat	The environment of an organism and the place where it is usually found
High water	Maximum level reached by the rising tide
Intertidal	Area on a shore that lies between Lowest Astronomical Tide (LAT) and Highest Astronomical Tide (HAT)
Longshore currents	The movement of currents parallel to the shore
Low water	The minimum height reached by the falling tide
Mean sea level	The average level of the sea surface over a defined period (usually a year or longer), taking account of all tidal effects and surge events
Megaripples	Bedforms with a wavelength of 0.6 to 10.0m and a height of 0.1 to 1.0m. These features are smaller than sand waves but larger than ripples
Metocean	The syllabic abbreviation of meteorology and oceanography
Neap tide	A tide that occurs when the tide-generating forces of the sun and moon are acting at right angles to each other, so the tidal range is lower than average
Nearshore	The zone which extends from the swash zone to the position marking the start of the offshore zone (~20m)

Numerical modelling	Refers to the analysis of coastal processes using computational models
Offshore	Area to seaward of nearshore in which the transport of sediment is not caused by wave activity
Quaternary Period	The last 2 million years of earth history incorporating the Pleistocene ice ages and the post-glacial (Holocene) Period
Sand	Sediment particles, mainly of quartz with a diameter of between 0.063mm and 2mm. Sand is generally classified as fine, medium or coarse
Sand wave	Bedforms with wavelengths of 10 to 100m, with amplitudes of 1 to 10m
Scour protection	Protective materials to avoid sediment being eroded away from the base of the foundations as a result of the flow of water.
Sea level	Generally refers to 'still water level' (excluding wave influences) averaged over a period of time such that periodic changes in level (e.g. due to the tides) are averaged out
Sea-level rise	The general term given to the upward trend in mean sea level resulting from a combination of local or regional geological movements and global climate change
Sediment	Particulate matter derived from rock, minerals or bioclastic matter
Sediment transport	The movement of a mass of sediment by the forces of currents and waves
Shallow water	Commonly, water of such depth that surface waves are noticeably affected by bottom topography. It is customary to consider water of depths less than half the surface wave length as shallow water
Shore platform	A platform of exposed rock or cohesive sediment exposed within the intertidal and subtidal zones
Significant wave height	The average height of the highest of one third of the waves in a given sea state
Spring tide	A tide that occurs when the tide-generating forces of the sun and moon are acting in the same directions, so the tidal range is higher than average
Storm surge	A rise in water level on the open coast due to the action of wind stress as well as atmospheric pressure on the sea surface
Surge	Changes in water level as a result of meteorological forcing (wind, high or low barometric pressure) causing a difference between the recorded water level and the astronomical tide predicted using harmonic analysis
Suspended sediment	The sediment moving in suspension in a fluid kept up by the upward components of the turbulent currents or by the colloidal suspension
Swell waves	Wind-generated waves that have travelled out of their generating area. Swell characteristically exhibits a

	more regular and longer period and has flatter crests than waves within their fetch
Tidal current	The alternating horizontal movement of water associated with the rise and fall of the tide
Tidal range	Difference in height between high and low water levels at a point
Tide	The periodic rise and fall of the water that results from the gravitational attraction of the moon and sun acting upon the rotating earth
Wave climate	Average condition of the waves at a given place over a period of years, as shown by height, period, direction etc.
Wave height	The vertical distance between the crest and the trough
Wavelength	The horizontal distance between consecutive bedform crests

7. METOCEAN CONDITIONS AND COASTAL PROCESSES

7.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) describes the metocean conditions and coastal processes of the Morlais Project (the Project).

2. The Project is being developed by Menter Môn Morlais Ltd. (Menter Môn) and will have a tidal generating capacity of up to 240 MW within the Morlais Demonstration Zone (MDZ).

3. The development of the Project will provide a consented tidal technology demonstration zone, specifically designed for the installation and commercial demonstration of multiple arrays of tidal energy devices. The Project will include communal infrastructure for tidal technology developers which provides a shared route to the cable landfall point via nine export cables, an onshore landfall substation, and an onshore electrical cable route to the existing electricity network via a grid connection substation (see **Chapter 4, Project Description**).

4. This chapter provides a summary description of key aspects relating to existing metocean conditions and coastal processes followed by an assessment of the magnitude and significance of the effects on the baseline conditions resulting from the construction, operation, repowering and decommissioning of the Project, as well as those effects resulting from cumulative interactions with other existing or planned projects.

5. This chapter of the ES was written by Royal HaskoningDHV metocean and coastal processes specialists and incorporates metocean data collected by Partrac (2014)[1], benthic survey data collected by Ocean Ecology (2018) and geophysical data collected by Partrac (2018), as well as numerical modelling outputs from HR Wallingford (2017, 2019). The assessment process has been informed by the following:

   - Interpretation of survey data specifically collected for the Project including bathymetry, sub-sea bed geology, sea bed sediments and metocean conditions;
   - Consideration of the existing evidence base regarding the effects of Project infrastructure on the physical and sedimentary environments;
   - Discussion and agreement with key stakeholders; and
   - Application of expert-based assessment and judgement by Royal HaskoningDHV.

6. The Project will install multiple technology types within the MDZ, and so the consent application is based on a Project Design Envelope (PDE), determined through knowledge of existing technology and the direction of future developments. Hence, the potential effects on metocean conditions and coastal processes have been assessed conservatively using realistic 'worst-case' scenarios for the Project.

7.2. RELEVANT GUIDANCE AND POLICY

7. This section outlines the relevant national and regional policy and guidance and industry guidance which has be used to support the compilation of this Metocean and Coastal Processes Chapter.

8. An overview of the relevant legislative context for the Project is provided in **Chapter 2, Policy and Legislation**.

7.2.1. Policy Statements

7.2.1.1. National Policy Statements

9. The Project is seeking consent for a Transport and Works Act Order from the Welsh Ministers and a Marine Licence from Natural Resources Wales (NRW). Although this Project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts for NSIPs is set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to metocean conditions and coastal processes include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011a); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011 (DECC, 2011b).

10. Details of specific policies within EN-1 and EN-3 used to inform this assessment are provided in **Table 7-1** below. The specific assessment requirements for metocean conditions and coastal processes are detailed, together with an indication of the paragraph numbers of the chapter where each is addressed.

Table 7-1 NPS EN-1 and EN-3 Assessment Requirements Relevant to Metocean Conditions and Coastal Processes

NPS Requirement	NPS Reference	ES Reference
'Where relevant, applicants should undertake coastal geomorphological and sediment transfer modelling to predict and understand impacts and help identify relevant mitigating or compensatory measures'	NPS EN-1 Section 5.5, paragraph 5.5.6	Modelling has been used to assess the baseline hydrodynamic regime and the impacts from the Project on the baseline hydrodynamic regime. A description of this modelling process is provided in **Appendix 7.1** (**Volume III**). Given the nature of the baseline environment (**Section 7.6**), it was deemed appropriate that the baseline sediment regime (including suspended sediment) has been defined based upon existing literature, previous similar

NPS Requirement	NPS Reference	ES Reference
		projects, geophysical and benthic survey and expert interpretation.
'The ES should include an assessment of the effects on the coast. In particular, applicants should assess: ▪ The impact of the proposed project on coastal processes and geomorphology, including by taking account of potential impacts from climate change. If the development will have an impact on coastal processes the applicant must demonstrate how the impacts will be managed to minimise adverse impacts on other parts of the coast. ▪ The vulnerability of the proposed development to coastal change, taking account of climate change, during the project's operational life and any decommissioning period.'	NPS EN-1 Section 5.5, paragraph 5.5.7	See **Section 7.7.5**, **7.7.6** and **7.7.7**
'The applicant should be particularly careful to identify any effects of physical changes on the integrity and special features of Marine Conservation Zones, candidate marine Special Areas of Conservation (SACs), coastal SACs and candidate coastal SACs, coastal Special Protection Areas (SPAs) and potential SCIs and Sites of Special Scientific Interest (SSSI).'	NPS EN-1 Section 5.5, paragraph 5.5.9	See **Section 7.7** and **7.7.1**
The assessment should include predictions of the physical effect that will result from the construction and operation of the required infrastructure and include effects such as the scouring that may result from the proposed development.	NPS EN-3 Section 2.6, paragraph 2.6.194	See **Section 7.7.5** and **7.7.6**
Mitigation measures which the IPC should expect the applicants to have considered include the burying of cables to a necessary depth and using scour protection techniques around offshore structures to prevent scour effects around them. Applicants should consult the statutory consultees on appropriate mitigation.	NPS EN-3 Section 2.6, paragraph 2.6.197	See **Section 7.7.3** and **94**

7.2.1.2. Marine Policy Statement

11. The Marine Policy Statement (MPS) adopted by all UK administrations in March 2011 provides the policy framework for the preparation of marine plans and establishes how decisions affecting the marine area should be made in order to enable sustainable development. The MPS sets out a vision of having 'clean, healthy, safe, productive and biologically diverse oceans and seas' by supporting the development of Marine Plans. It also sets out the framework for environmental, social and economic considerations that need to be considered in marine planning. Regarding the topics covered by this chapter the key reference is in **Table 7-2**.

7.2.1.3. Welsh National Marine Plan

12. By adopting the MPS, the Welsh Government committed to the requirement to introduce Marine Plans for Wales.

13. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the Welsh National Marine Plan (WNMP). The Plan is being developed in accordance with the Marine and Coastal Access Act (MCAA) 2009, the MPS and the Maritime Spatial Planning Directive, a draft version has been issued for consultation (discussed further in **Chapter 2, Policy and Legislation**).

14. Objective 10 of the WNMP, “to maintain and enhance the resilience of marine ecosystems and the benefits they provide in order to meet the needs of present and future generations”, is of relevance to this chapter as this covers policies and commitments on the wider ecosystem, as set out in the MPS including those to do with the Marine Strategy Framework Directive and the Water Framework Directive, as well as other environmental, social and economic considerations.

15. The draft WNMP makes reference to the policies shown in **Table 7-2**which are particularly relevant to the Project.

7.2.1.4. Planning Policy Wales

16. Planning policy for Wales is set out in the document Planning Policy Wales (Welsh Government, 2016). The planning policy document outlines the Welsh Government’s approach to facilitating the delivery of the aims set out in Energy Wales: A Low Carbon Transition (Welsh Government, 2012b), as well as UK wide and European renewable energy targets, including obligations under the Renewable Energy Directive (2009/28/EC). The relevant points within the policy relating to metocean and coastal processes are outlined in **Table 7-2**.

17. The following Planning Policy Technical Advice Note (TAN) has been reviewed within this chapter of the Morlais ES:

- TAN 14: Coastal Planning.

7.2.2. Regional Plans

7.2.2.1. Anglesey and Gwynedd Joint Local Development Plan

18. Development of the Project will support those objectives of the 2017 Anglesey and Gwynedd JLDP, aimed at promoting the development of renewable or low carbon energy technologies. The Project will prioritise maximising opportunities for local communities directly via employment and indirectly via the establishment of a local supply chain.

19. Of the policies contained in the JLDP, those presented in **Table 7-2** are considered to be of relevance to the proposed development.

7.2.2.2. Shoreline Management Plan

20. A Shoreline Management Plan (SMP) provides a large-scale assessment of the risks associated with coastal evolution and presents a policy framework to address these risks to people and the developed, historic and natural environment in a sustainable manner. In doing so, an SMP is a high-level document that forms an important part of the Department for Environment, Food and Rural Affairs (Defra) strategy for flood and coastal defence (Defra, 2001).

21. The SMP is a non-statutory policy document for coastal defence management planning. It takes account of other existing planning initiatives and legislative requirements and is intended to inform wider strategic planning. The shoreline of Wales is divided into a number of Policy Development Zones (PDZ). The coastal area of the Project lies within PDZ17 – Holy Island and West Anglesey (Twyn y Parc to Twyn Cliperau).

7.2.3. Policy Summary

22. The relevant nation National and Regional policy requirements relevant to the Morlais Metocean and Coastal Processes ES chapter is shown in **Table 7-2**.

Table 7-2 National and Regional Policy Requirements Relevant to Metocean and Coastal Processes

Policy Description	Reference	ES Reference
MPS		
Marine plan authorities should not consider development which may affect areas at high risk and probability of coastal change unless the impacts upon it can be managed. Marine plan authorities should seek to minimise and mitigate any geomorphological changes that an activity or development will have on coastal processes, including sediment movement.	Section 2.6.8.6	The potential impacts on coastal processes associated with the construction, operation and decommissioning of the Project is assessed in **Section 7.7.7**, **7.7.8** and **7.7.9**.
Draft WNMP		
Proposals should demonstrate how they are resilient to coastal change and flooding over their lifetime.	SOC_08: Resilience to coastal change and flooding	Coastal change has been considered when assessing potential impacts and effects, see **Section 7.6.6**.
Proposals are encouraged that: ▪ Demonstrate that they have no significant adverse impact upon coastal processes; ▪ Minimise the risk of coastal change and flooding; and ▪ Align with the relevant Shoreline Management Plan	SOC_09: Effects on coastal change and flooding	The potential impacts on coastal processes associated with the construction, operation and decommissioning of the Project is assessed in **Section 7.7.7**, **7.7.8** and **7.7.9**. The Project will not affect the Shoreline Management Plan and allowance has been made for natural erosion (including allowances for climate change) during the project design. Embedded mitigation to minimise potential impacts at the coast of cable installation and operation are described in **Section 7.7.3**.

Policy Description	Reference	ES Reference
Proposals should demonstrate that they have considered the impacts of climate change and have incorporated appropriate adaption measures, taking into account Climate Change Risk Assessments for Wales.	SOC_11: Resilience to climate change	Climate change impacts have been considered when assessing potential impacts and effects, see **Section 7.6.6**.
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: ▪ a) Avoid adverse effects; and/or ▪ b) Minimise effects where they cannot be avoided; and/or ▪ c) Mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative and in-combination impacts of the Project have been considered in **Section 7.7.8** and **Chapter 26, Cumulative and In-Combination Effects**.
Planning Policy Wales		
As part of understanding the characteristics of coastlines it should be recognised that sea level rise, storm surge, wave action and changes in coastal morphology and sediment supply can lead to both direct and indirect effects at the coast. Uncertainty is further exacerbated by the effects of climate change.	Section 6.5.14	Climate change impacts have been considered when assessing potential construction, operation and decommissioning phase impacts and effects, see **Section 7.6.6**.
It is not appropriate for development in one location to unacceptably add to the impacts of physical change to the coast in another location.	Section 6.5.15	Cumulative and in-combination impacts of the Project have been considered in **Section 7.7.8** and **Chapter 26, Cumulative and In-Combination Effects**.
SMPs will influence whether development itself can be justified or how it should be designed.	Section 6.5.17	The Project will not affect the Shoreline Management Plan and allowance has been made for natural erosion (including allowances for climate change) during the project design.
Anglesey and Gwynedd Joint Local Development Plan (JLDP)		
Within the coastal areas that are protected as a Heritage Coast an emphasis will be placed on protecting and promoting the natural beauty of the coast, facilitating access for the public and public appreciation, maintaining the environmental quality of the waterfronts and promoting sustainable types of social and economic development.	AMG 4: Coastal Protection	Holyhead Mountain Heritage Coast has been considered when assessing potential impacts during the construction, operation and decommissioning of the Project.
All impacts on landscape character, heritage assets and natural resources have been adequately mitigated, ensuring that the special qualities of all locally, nationally and internationally important landscape, biodiversity and heritage designations,	ADN 3: Other Renewable Energy and Low Carbon Technologies	Impacts on Holy Island Coast SSSI/SAC, Anglesey AONB and Holyhead Mountain Heritage coast have been assessed in **Section 7.7** and mitigation proposed in **Sections 7.7.3** and **7.7.4**

Policy Description	Reference	ES Reference
including, where appropriate, their settings are conserved or enhanced.		
The Councils will manage development so as to conserve and where appropriate enhance the Plan area's distinctive natural environment, countryside and coastline, and proposals that have a significant adverse effect on them will be refused unless the need for and benefits of the development in that location clearly outweighs the value of the site or area and national policy protection for that site and area in question.	PS 19: Conserving and Where Appropriate Enhancing the Natural Environment	Please see **Chapter 19, Onshore Ecology**; **Chapter 24, Seascape, Landscape and Visual Impact Assessment**, **Chapter 25, Socioeconomics, Tourism and Recreation**
Proposals that are likely to cause direct or indirect significant harm to Local Nature Reserves (LNR), Wildlife Sites (WS) 1 or regionally important geological / geomorphologic sites (RIGS) must have overriding economic and social benefit and not cause unacceptable harm	AMG 6: Protecting Sites of Regional or Local Significance	See **Section 7.7.7, 7.7.8** and **7.7.9** for the impact assessment results.
Wellbeing of Future Generations (Wales) Act 2015		
A nation which maintains and enhances a biodiverse natural environment with healthy functioning ecosystems that support social, economic and ecological resilience and the capacity to adapt to change (for example climate change).	A resilient Wales	See **Section 7.7.7, 7.7.8** and **7.7.9** for the impact assessment results.

7.2.4. Industry Guidance

23. Industry guidance on the generic requirements, including spatial and temporal scales, for metocean and coastal processes studies associated with tidal array developments is provided in several documents (some of which are specifically written for offshore wind farms but are also of relevance here):

- Metocean Procedures Guide for Offshore Renewables (IMarEST, 2018);
- Offshore wind farms: guidance note for Environmental Impact Assessment in respect of Food and Environmental Protection Act (FEPA) and Coast Protection Act (CPA) requirements: Version 2 (Cefas, 2004);
- Coastal Process Modelling for Offshore Wind farm Environmental Impact Assessment (COWRIE, 2009);
- Review of Cabling Techniques and Environmental Effects applicable to the Offshore Wind Farm Industry (BERR, 2008);
- General advice on assessing potential impacts of and mitigation for human activities on Marine Conservation Zone (MCZ) features, using existing regulation and legislation (JNCC and Natural England, 2011); and
- Guidelines for data acquisition to support marine environmental assessments of offshore renewable energy projects (Cefas, 2011).

7.3. CONSULTATION

24. Consultation is an important part of the Transport and Works Act Order (TWAO) application process. To date, consultation regarding metocean conditions and coastal processes has been conducted through the Scoping Opinion for the Scoping Report (Royal HaskoningDHV, 2018). The Scoping responses received are summarised in **Table 7-3**.

Table 7-3 Scoping Opinion Responses

Consultee	Comment	Response/where addressed in the ES
Planning Inspectorate	Reduced energy in tidal currents from energy removed by tidal devices. Paragraph 11.2.2.1 of the Scoping Report requests to scope this matter out on the basis that previous studies for other projects such as Perpetuus Tidal Energy Centre and SeaGen have found little evidence of significant changes to tidal strength downstream of devices and have predicted no significant impacts on coastal processes. Whilst this is noted, the Perpetuus Tidal Energy Centre is a 30MW development and it is not accepted that the findings of such previous studies are directly applicable to the Proposed Works, which is 240MW and is seeking a wide project design envelope. In addition, the request to scope this matter out is contradicted by Table 7-1 of the Scoping Report which states that removal of tidal energy from the environment may result in increased sedimentation downstream of TEC devices and that significance of impact is unknown. It is therefore not agreed that this matter can be scoped out of the ES. The ES should assess potential hydrodynamic impacts from the presence of offshore infrastructure.	The potential impacts on the baseline hydrodynamic conditions from the presence of offshore infrastructure are assessed in **Section 7.7.8**.
Planning Inspectorate	Changes to wave climate from submerged and surface piercing infrastructure. The Applicant states that EIA and monitoring studies from other surface piercing technologies, namely offshore wind, have found no evidence to suggest that surface piercing devices significantly alter wave climate or strength inshore of project areas. No specific studies have been referenced and it is unclear if such studies conducted for different technology types will be applicable to the Proposed Works' tidal technologies, which may include substantially different structures to wind turbines. On the basis of the information provided at this stage, it is not agreed this matter can be scoped out of the ES. The ES should assess potential hydrodynamic impacts from the presence of offshore infrastructure.	The potential impacts on the baseline wave climate from the presence of offshore infrastructure are assessed in **Section 7.7.8**.
Planning Inspectorate	The Scoping Report provides limited detail on how the baseline will be characterised. The Applicant should make efforts to discuss and agree the approach to baseline characterisation with NRW. The proposed coastal process conceptual modelling should inform the need of any further field surveys e.g. bathymetric and/ or geophysical investigations. Sediment samples should also be taken in sediment laden seabed areas to determine sediment type,	The data sources used to inform the conceptual understanding of the baseline environment are listed in **Section 7.5.2**. The baseline environment is described in **Section 7.6**.

Consultee	Comment	Response/where addressed in the ES
	composition and sediment volume that could potentially be suspended through the cable trenching activities. Topographical data from the landfall location should be provided to inform any impacts on the beach profile and sediment morphology from cable landfall.	
Planning Inspectorate	The Scoping Report has not detailed how the potential impacts will be assessed. The methodology must be detailed in the ES. It is considered that modelling will be required to predict the anticipated increase in suspended sediment from the Proposed Works. The ES should include details of the parameter inputs to the model and provide an explanation/justification of any worst-case scenario that has been assumed.	The methodology used for the assessment of potential impacts is described in **Section 7.4.1**. Modelling has been used to assess the baseline hydrodynamic regime and the impacts from the Project on the baseline hydrodynamic regime. A description of this modelling process is provided in **Appendix 7.1** (**Volume III**). Given the nature of the baseline environment (**Section 7.6**), it was deemed appropriate that the baseline sediment regime (including suspended sediment) has been defined based upon existing literature, previous similar projects, geophysical and benthic survey and expert interpretation.
Planning Inspectorate	The Scoping Report notes the potential for *Sabellaria alveolata* and *Modiolus modiolus* reef to be present in the offshore scoping area. The Applicant should take into account NRW's response (see Appendix 1 of this Scoping Opinion) stating that several areas of *Sabellaria alveolata* have developed into *Sabellaria* reef. Any likely significant effects on *Sabellaria* reef should be assessed within the ES. The ES should consider potential direct impacts from construction and also the potential impacts from maintenance activities on reef that may colonise the cables during the operational phase.	The potential impacts on Sabellaria reef as a result of the construction, operation and decommissioning phase of the Project are considered in **Chapter 9, Benthic and Intertidal Ecology.**
Planning Inspectorate	It is understood that the type and locations of TEC devices within the offshore area will not be determined by the time of application. As such, the ES should consider a worst-case scenario of habitat loss. When assessing the potential impacts from loss of habitat, the ES should also give consideration to habitat loss resulting from the introduction of any scour and cable protection.	Worst-case scenarios of habitat loss as a result of the construction, operation and decommissioning phase of the Project are considered in **Chapter 9, Benthic and Intertidal Ecology.**
Planning Inspectorate	Potential impacts due to change in sediment regime are included in Table 8-4. However, Table 8-2 identifies potential impacts to benthic ecology interest features of designated marine and coastal sites due to changes in	The likely significant effects on intertidal and subtidal benthic ecology from changes to physical

Consultee	Comment	Response/where addressed in the ES
	coastal processes, sedimentology and hydrodynamic regime in Table 8-2. The ES should assess the likely significant effects on intertidal and subtidal benthic ecology from changes to physical process (e.g. alteration to flow conditions, waves regime and sediment transport pathways).	processes as a result of the construction, operation and decommissioning phase of the Project are considered in **Chapter 9, Benthic and Intertidal Ecology.**
Planning Inspectorate	The ES should assess the likely significant effects from increased turbidity on larvae of fish and shellfish species.	The likely significant effects from increased turbidity on larvae of fish and shellfish species as a result of the construction, operation and decommissioning phase of the Project are considered in **Chapter 10, Fish and Shellfish Ecology.**
Natural Resources Wales	Zone of influence and impact pathway descriptions have not been provided in sufficient detail for scrutiny in the EIA scoping report. We are therefore unable to confirm whether we agree with the impact zone of influence or impact pathways. This presents implications for the advice that can currently be provided with respect to designated sites, cumulative impacts and activities to be scoped out. It is not known at present what devices will be deployed in the demonstration zone area etc therefore it will be important that the zone of influence identifies the maximum environmental impact based on realistic worst-case scenarios. The baseline evidence used to determine the zone of influence will need to be clearly stated in the ES.	The zone of influence approach originally envisaged has subsequently been replaced by hydrodynamic modelling to assess the impacts on the hydrodynamic regime in a quantifiable and rigorous manner.
Natural Resources Wales	Little information is currently provided in the EIA scoping report with regard to cable protection requirements. It is not defined at present where and how much cable protection will be required if the export cables are surface laid on exposed bedrock and protected by rock armour or concrete mattresses. Cable protection could include permanent rock armour protection on the seabed potentially altering current flows near the seabed, inducing sediment scour and potentially altering sediment transport pathways near the coast. Worst-case scenarios for cable protection will need to be assessed in the ES.	The worst-case scenario for cable protection is described in **Section 7.7.6**. The effects of cable protection on baseline conditions are described in **Section 7.7.8**.
Natural Resources Wales	The baseline characterisation work proposed within the EIA scoping report is limited. Clarification is required regarding how the applicant intends to describe the site selection process for the tidal energy devices and grid connection route if detailed hydrodynamic, bathymetric and geophysical investigations are not carried out to provide the necessary baseline evidence. We advise that the applicant should use accurate bathymetry and geophysical survey data of the demonstration zone to inform their decision on the export cable route pathways through the proposed demonstration zone. Sediment samples should also be taken in sediment laden seabed areas to determine sediment type, composition and sediment volume that could potentially be suspended through the cable trenching activities.	The baseline characterisation has been informed by geophysical, subtidal grab sample, intertidal and metocean surveys, as described in **Section 7.5.2**.

Consultee	Comment	Response/where addressed in the ES
Natural Resources Wales	The EIA scoping report suggests that the applicant will not be conducting hydrodynamic investigations of the demonstration zone area. If that is the case, we seek clarification regarding how the applicant intends to assess potential hydrodynamic impacts from the presence of the offshore infrastructure that they are responsible for (i.e. offshore hub, inter array and export cables and associated cable protection) and the tidal energy devices themselves.	In recognition of this comment, hydrodynamic investigations have been undertaken using numerical modelling techniques and geomorphological interpretation of the results to assess the impacts of the Project on the baseline hydrodynamic regime. Description of this numerical modelling process is provided in **Appendix 7.1** (**Volume III**).
Natural Resources Wales	Potential impacts on metocean conditions and coastal processes only includes impacts during the operational phase of the proposed development (see table 7.1). The other phases of the project life (construction and decommissioning) should also be considered within the ES. For example, during the construction phase there could be impacts caused by the cable laying activities, such as alteration to the seabed morphology caused by presence of rock armour protection on the seabed. This could have a significant impact on coastal processes if located across an active sediment transport pathway. There could also be a potential for sediment scour downstream of the structure and alteration of flow near the seabed.	The impact assessment covers not only the construction phase but also the operation and decommissioning phases, as described in **Section 7.7.8** and **7.7.9**.
Natural Resources Wales	Table 7-1 describes the potential impact ‘increased suspended sediment from reduced water energy’. It is unclear how reduced water energy will increase suspended sediment concentrations. Reduced water energy may increase sedimentation of suspended material; is this what is meant?	Noted, further clarification is provided in the assessment of Operational Impacts (**Section 7.7.6**).
Natural Resources Wales	Again, it is unclear how potential impacts relating to metocean conditions and sediment transport, and coastal processes be assessed for impact significance in the EIA without conducting hydrodynamic modelling studies pre and post tidal array/cable installation (see Table 7-1). Without physically measuring or modelling the change in the energy potential downstream of the devices and alteration to the wave directions under different wave conditions, it may not be possible to determine significance and magnitude of impact on the coastal processes.	Modelling has been used to assess the impacts on the hydrodynamic regime and description of this modelling process is provided in **Appendix 7.1** (**Volume III**).
Natural Resources Wales	With reference to Table 7-1 we recommend that consideration should be given in the ES to the alteration of the near bed currents and sediment transport pathways caused by rock armour protection on the seabed, not just the tidal energy devices.	The effects of cable protection have been considered in **Section 7.7.8**.
Natural Resources Wales	Regarding ‘EIA baseline characterisation’ NRW welcome the inclusion of a conceptual model to describe the hydrodynamic and coastal process. A coastal processes conceptual model is a useful way to identify where there are gaps in existing baseline evidence which may then inform the requirement for further metocean data collection through field surveys. At the scoping stage, metocean and	The data sources used to inform the conceptual understanding of the baseline environment are listed in **Section 7.5.2**.

Consultee	Comment	Response/where addressed in the ES
	coastal processes field data collection should not be ruled out (see section 7.1.3).	The baseline environment is described in **Section 7.6**.
Natural Resources Wales	We advise that hydrodynamic modelling to inform the EIA impact assessment should also not be ruled out at the scoping stage until it is confirmed that there is enough baseline evidence to qualify and quantify the EIA impact assessment process for hydrodynamics, sediment transport and coastal processes.	Modelling has been used to assess the impacts on the hydrodynamic regime and description of this modelling process is provided in **Appendix 7.1** (**Volume III**).
Natural Resources Wales	It is recommended that the coastal processes baseline characterisation needs to also include topographical data at the landfall location which may be used to inform any potential impacts on the beach profile and sediment morphology arising from the cable landfall of the export cable from offshore to onshore and the construction of a transition pit.	Morphological and sedimentary characteristics at the landfall have been addressed in **Section 7.6.10**.Geology and Coastal Processes at the Landfall
Natural Resources Wales	Further information is required regarding how the potential impacts to the physical processes caused by the deployment of multiple tidal energy devices will be qualitatively and quantitatively assessed using a non-numerical approach i.e. development of a conceptual model. The physical processes impact assessment is an important assessment as any alteration to the flow conditions, waves regime and sediment transport pathways caused by the presence of the tidal devices and the associated infrastructure will potentially impact on the intertidal and subtidal benthic ecology, water quality and coastal morphodynamics. This in turn could then affect the integrity of the protected sites designated under the Habitats directive and affect the ecological status defined under the Water Framework Directive.	Modelling has been used to assess the impacts on the hydrodynamic regime and description of this modelling process is provided in **Appendix 7.1** (**Volume III**). Hydrodynamic impacts have then been interpreted from the modelling results. Expert assessment has been used elsewhere (e.g. effects on wave regime and sediment transport regime).
Natural Resources Wales	We disagree that the offshore physical processes associated with reduced energy in tidal currents from energy removed by tidal devices should be scoped out from the EIA. It is not clear at this stage what devices will be deployed within the demonstration zone. PTEC are potentially generating 30MW of power whilst the demonstration zone will potentially be generating 240 MW of power. The scale of both projects is very different and ruling out the effects caused by a reduction in energy based on the findings of a much smaller project is not acceptable at this stage.	The potential impacts on the baseline hydrodynamic conditions from the presence of offshore infrastructure are assessed in **Section 7.7.8**. This impacts assessment is informed by numerical modelling which is described in **Appendix 7.1** (**Volume III**).
Natural Resources Wales	There has been no inclusion of tidal current data in the demonstration zone which shows the magnitude and direction of flow over the zone to substantiate the assumption that the suspended sediments would rapidly disperse. We agree that in fast flowing currents, dispersion of suspended sediments could occur rapidly and the potential for smothering would be reduced as a result (see table 7.2). However, there is no baseline evidence presented in the metocean section that supports this assessment of impact. We advise that further evidence is presented to show the magnitude and direction of the tidal currents in the nearshore and intertidal areas which are often much smaller than those experienced offshore, and	The baseline hydrodynamic conditions are assessed in **Section 7.6**. These have been informed by numerical modelling which is described in **Appendix 7.1** (**Volume III**).

Consultee	Comment	Response/where addressed in the ES
	which may not be enough to promote rapid dispersion of suspended sediments and potential contaminants released through trenching activities over this zone.	
Natural Resources Wales	Extreme sea levels can be obtained for this coastline for a range of probability flood events including that of climate change allowances. These extreme sea levels would allow for surge conditions but not wave action. To obtain the levels a request may be made to our data distribution team.	Extreme sea levels are described as part of the baseline environment in **Section 7.6**.
Natural Resources Wales	We welcome the acknowledgement of potential impacts to benthic ecology interest features of designated marine and coastal sites due to changes in coastal processes, sedimentology and hydrodynamic regime in table 8.2. We note, however, that only potential impacts due to change in sediment regime are included in table 8.4 Potential impacts on benthic ecology. We wish to draw the applicant's attention to our comments relating to coastal process aspects of the EIA Scoping Report. Specifically, we would welcome clarity on how the potential impacts to the physical processes caused by the deployment of multiple tidal energy devices and associated infrastructure will be adequately assessed using a nonnumerical (conceptual model) approach, and how this will be applied in the context of potential impacts to intertidal and subtidal benthic ecology, water quality and coastal morphodynamics arising due to physical process impacts (alteration to flow conditions, waves regime and sediment transport pathways).	See **Section 7.7.5** and **Section 7.7.6** for operational impacts. The following chapters have utilised this information to inform the impact assessment sections of those chapters; **Chapter 8, Marine Water and Sediment Quality**, **Chapter 9, Benthic and Intertidal Ecology** as suggested.
Natural Resources Wales	We note that the Offshore Scoping Zone now includes the sea area between the demonstration zone and the shore. Additional multibeam / acoustic survey and benthic ground-truthing will be needed in this area to inform the benthic impact assessment associated with the export cable route from the Lease Area if not already available.	The marine geophysical survey covers all areas of the MDZ, shown in **Figure 7-1** (**Volume II**).

7.4. ASSESSMENT METHODOLOGY

25. To meet the requirements of the guidance documents described in **Section 7.2**, the assessment approach has adopted the following stages:

- Review of existing relevant data and information;
- Acquisition of additional project-specific data to fill any gaps (including additional numerical modelling of effects on the tidal regime);
- Formulation of a conceptual understanding of baseline conditions;
- Consultation and agreement with the regulators regarding proposed assessment approaches;
- Determination of the worst-case scenarios;
- Consideration of embedded mitigation measures; and
- Assessment of effects using data analysis, numerical modelling outputs, and expert-based judgements by Royal HaskoningDHV.

7.4.1. Impact Assessment Methodology

26. As described in **Chapter 5, EIA Methodology**, the assessment of effects on metocean conditions and coastal processes is predicated on a Source-Pathway-Receptor (S-P-R) conceptual model, whereby the source is the initiator event, the pathway is the link between the source and the receptor impacted by the effect, and the receptor is the receiving entity.

27. An example of the S-P-R conceptual model is provided by cable installation which disturbs sediment on the sea bed (source). This sediment is then transported by tidal currents until it settles back to the sea bed (pathway). The deposited sediment could change the composition and elevation of the sea bed (receptor).

28. Consideration of the potential effects of the Project on the metocean conditions and coastal processes is carried out over the following spatial scales:

- Near-field: the area within the immediate vicinity (tens or hundreds of metres) of the Project and along the offshore cable corridor; and
- Far-field: the wider area that might also be affected indirectly by the Project (e.g. due to disruption of waves, tidal currents or sediment pathways).

29. Four main phases of development are considered, in conjunction with the present-day baseline, over the life-cycle of the Project. These are:

- Construction phase;
- Operation and maintenance phase;
- Repowering phase and
- Decommissioning phase.

30. A repowering of a device/array is defined as the end of a berth/array demonstration cycle, at which time the device, device foundations, support structures, electrical hubs, tenant monitoring equipment, and inter-array cabling will be removed, in line with procedures adopted during decommissioning. Once all developer owned assets listed above have been removed, the Project will then have capacity for ‘repowering’ the berth would then be available for ‘repowering’ where new devices may be installed to utilise the vacated berth, or be installed at a new berth for further demonstration.

31. For the purposes of this chapter, the effects and impacts of repowering are considered to be the same as assessed for construction and decommissioning.

32. For the effects on metocean conditions and coastal processes, the assessment follows two approaches. The first type of assessment is impacts on metocean conditions and coastal processes whereby several discrete direct receptors are identified. These include certain morphological features with inherent value, such as:

- Offshore sand ridges / sandbanks – these morphological features play an important role in influencing the baseline tidal, wave and sediment transport regimes; and
- Beaches and sea cliffs - these shoreline morphological features play an important natural coastal defence role at the coast and are features which form part of the

designated sites of Holy Island Coast Site of Special Scientific Interest (SSSI)/Special Area of Conservation (SAC), Anglesey Area of Outstanding Natural Beauty (AONB) and Holyhead Mountain Heritage Coast.

33. The impact assessment incorporates a combination of the sensitivity of the receptor, its value (if applicable) and the magnitude of the change to determine a significance of impact. **Chapter 5, EIA Methodology** provides an overview of this approach to the assessment of impacts.

34. In addition to identifiable receptors, the second type of assessment covers changes to metocean conditions and coastal processes which in themselves are not necessarily impacts to which significance can be ascribed. Rather, these changes (such as a change in the wave climate, a change in the tidal regime or a change in suspended sediment concentrations) represent effects which may manifest themselves as impacts upon other receptors, most notably marine sediment and water quality, benthic ecology, and fish and shellfish ecology (e.g. in terms of increased suspended sediment concentrations, or erosion or smothering of habitats on the sea bed).

35. Hence, the two approaches to the assessment of metocean conditions and coastal processes are:

- Situations where potential impacts can be defined as directly affecting receptors which possess their own intrinsic morphological value. In this case, the significance of the impact is based on an assessment of the sensitivity of the receptor and magnitude of effect at the receptor location, taking into the near-field or far-field nature of the effect from the receptor. An impact significance matrix is used as a guide to determine the impact significance; and
- Situations where effects (or changes) in the baseline metocean conditions and coastal processes may occur which could manifest as impacts upon receptors other than metocean conditions and coastal processes. In this case, the magnitude of effect is determined in a similar manner to the first assessment method but the significance of impacts on other receptors is made within the relevant chapters of the ES pertaining to those receptors.

7.4.1.1. Sensitivity, Value and Magnitude

36. The sensitivity of a receptor is dependent upon its:

- *Tolerance* to an effect (the extent to which the receptor is adversely affected by an effect);
- *Adaptability* (the ability of the receptor to avoid adverse impacts that would otherwise arise from an effect); and
- *Recoverability* (a measure of a receptor’s ability to return to a state at, or close to, that which existed before the effect caused a change).

37. In addition, a value component may also be considered when assessing a receptor. This ascribes whether the receptor is rare, protected or threatened.

38. The magnitude of an effect is dependent upon its:

- Scale (i.e. size, extent or intensity);
- Duration;
- Frequency of occurrence; and
- Reversibility (i.e. the capability of the environment to return to a condition equivalent to the baseline after the effect ceases).

39. The sensitivity and value of discrete morphological receptors and the magnitude of effect are assessed using expert judgement and described with a standard semantic scale. Definitions for each term are provided in **Table 7-4**, **Table 7-5** and **Table 7-6**. These expert judgements of receptor sensitivity, value and magnitude of effect are guided by the conceptual understanding of baseline conditions.

Table 7-4 Definitions of Sensitivity Levels for a Morphological Receptor

Sensitivity	Definition
High	Tolerance: Receptor has very limited tolerance of effect. Adaptability: Receptor unable to adapt to effect. Recoverability: Receptor unable to recover resulting in permanent or long-term (greater than ten years) change.
Medium	Tolerance: Receptor has limited tolerance of effect. Adaptability: Receptor has limited ability to adapt to effect. Recoverability: Receptor able to recover to an acceptable status over the medium term (5-10 years).
Low	Tolerance: Receptor has some tolerance of effect. Adaptability: Receptor has some ability to adapt to effect. Recoverability: Receptor able to recover to an acceptable status over the short term (1-5 years).
Negligible	Tolerance: Receptor generally tolerant of effect. Adaptability: Receptor can completely adapt to effect with no detectable changes. Recoverability: Receptor able to recover to an acceptable status near instantaneously (less than one year).

Table 7-5 Definitions of the Different Value Levels for a Morphological Receptor

Value	Definition
High	Value: Receptor is designated and/or of national or international importance for marine geology, oceanography and physical processes. Likely to be rare with minimal potential for substitution. May also be of significant wider-scale, functional or strategic importance.
Medium	Value: Receptor is not designated but is of local to regional importance for marine geology, oceanography and physical processes.
Low	Value: Receptor is not designated but is of local importance for marine geology, oceanography and physical processes.
Negligible	Value: Receptor is not designated and is not deemed of importance for marine geology, oceanography and physical processes.

Table 7-6 Definitions of Magnitude of Effect Levels for Metocean Conditions and Coastal Processes

Magnitude	Definition
High	Scale: A change which would extend beyond the natural variations in background conditions. Duration: Change persists for more than ten years. Frequency: The effect would always occur. Reversibility: The effect is irreversible.
Medium	Scale: A change which would be noticeable from monitoring but remains within the range of natural variations in background conditions. Duration: Change persists for 5-10 years. Frequency: The effect would occur regularly but not all the time. Reversibility: The effect is very slowly reversible (5-10 years).
Low	Scale: A change which would barely be noticeable from monitoring and is small compared to natural variations in background conditions. Duration: Change persists for 1-5 years. Frequency: The effect would occur occasionally but not all the time. Reversibility: The effect is slowly reversible (1-5 years).
Negligible	Scale: A change which would not be noticeable from monitoring and is extremely small compared to natural variations in background conditions. Duration: Change persists for less than one year. Frequency: The effect would occur highly infrequently. Reversibility: The effect is quickly reversible (less than one year).

7.4.1.2. Impact Significance

40. Following the identification of receptor sensitivity and value, and magnitude of effect, it is possible to determine the significance of the impact. A matrix is presented in **Table 7-7** as a framework to guide how a judgement of the significance is determined.

Table 7-7 Impact Significance Matrix

		Negative Magnitude				**Beneficial Magnitude**			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

41. Through use of the matrix shown in **Table 7-7,** an assessment of the significance of an impact can be made in accordance with the definitions in **Table 7-8**.

Table 7-8 Impact Significance Definitions

Impact Significance	Definition
Major	Very large or large change in receptor condition, both adverse or beneficial, which are likely to be important considerations at a regional or district level because they contribute to achieving national, regional or local objectives, or, could result in exceedance of statutory objectives and / or breaches of legislation.

Impact Significance	Definition
Moderate	Intermediate change in receptor condition, which is likely to be an important consideration at a local level.
Minor	Small change in receptor condition, which may be raised as a local issue but is unlikely to be important in the decision-making process.
Negligible	No discernible change in receptor condition.

42. For the purposes of this ES, 'major' and 'moderate' impacts are deemed to be significant (in EIA terms). In addition, whilst 'minor' impacts may not be significant, it is important to distinguish these from other non-significant (negligible) impacts as they may contribute to significant impacts cumulatively.

7.4.1.3. Cumulative Impact Assessment

43. Cumulative impacts are assessed through consideration of the extent of influence of changes to metocean conditions and coastal processes arising from the Project alone and those arising from the Project cumulatively or in combination with other developments including the Deep Green (DG) Holyhead Deep Project Phase 1 (0.5) and DG Holyhead Deep Array Project.

7.5. SCOPE

7.5.1. Study Area

44. The MDZ is in the eastern Irish Sea, encompassing a sea bed area of approximately 35 km^2 and an export cable corridor of 4.75 km^2 (plus an intertidal area of 0.01 km^2), totalling an area of 39.76 km^2 for the Offshore Development Area (OfDA). Its nearest point is located approximately 0.5 km from the west coast of Anglesey. Offshore cables connect Project across an offshore cable corridor to the east of the MDZ and then to the landfall near Penrhos Feilw (**Figure 1-1, Volume II**).

7.5.2. Data Sources

45. Information to support this chapter of the ES has come from several sources (**Table 7-9**).

Table 7-9 Data Sources

Data	Year	Coverage	Confidence	Notes
Geophysical Survey	2018	MDZ, buffer zone and Abraham's Bosom	High	High-resolution sea bed bathymetry, seabed texture and morphological features, and shallow geology using multibeam echosounder, side-scan sonar, and boomer (Partrac, 2018).
Subtidal Grab Sample Survey	2018	MDZ and buffer zone	High	Drop-down camera and five grab samples at selected suitable sites (Ocean Ecology, 2018).
Intertidal Survey	2018	Abraham's Bosom	High	Unmanned Aerial Vehicle (UAV) survey and intertidal walkover (Ocean Ecology, 2018).
Metocean Survey	2014	MDZ	High	Bottom-mounted Acoustic Doppler Current Profilers (ADCP) deployed for a continuous 40-day period in November and December 2014 at two locations.

46. A geophysical survey of the MDZ (plus a 1 km buffer zone to the -10 m Chart Datum (CD) contour around it) was completed between 22nd April 2018 and 19th May 2018 (Partrac, 2018) (**Table 7-9**). Survey lines were completed at 125 m spacing for most of the site with a bearing of 24 ° (tidal flow direction) (**Figure 7-1, Volume II**).

47. In the nearshore zone, the line spacing was decreased to between 30 m and 50 m. Where vessel safety allowed, the survey was extended up to the -5 m CD contour, along the western coast, except for within the bay approaching the landfall known as Abraham's Bosom. The shallow water in this bay was mapped to the 0 m CD contour or as far inshore as possible without compromising vessel safety. Five cross lines were completed at suitable locations to 'tie together' the main lines.

48. Ocean Ecology (2018) also completed an intertidal survey around the proposed cable landfall in Abraham's Bosom (**Table 7-9**) (**Figure 7-2, Volume II**). The area was flown on 30th August 2018 at low spring tide using a UAV to capture high-resolution aerial imagery that was subsequently used to create an ortho-mosaic map of key habitats (**Figure 7-2, Volume II**). The remote sensing was followed by an intertidal walkover survey on 14th September 2018.

Table 7-10 Location of Grab Samples and Drop-Down Camera Stills (Ocean Ecology, 2018) (corresponding to Figure 7-2, Volume II)

Location	Grab Samples	Drop-down Camera
Demonstration Zone	Location 41	Location 33
Buffer Zone	Locations 15 and 20	Location 6
Abraham's Bosom	Location 42	Location 3

49. A metocean survey was undertaken between November and December 2014 by Partrac and provided to Mentor Môn (courtesy of OpenHydro). This involved the deployment of ADCPs at two locations in the MDZ. Site 1 was in approximately 37 m water depth and Site 2 in approximately 35 m water depth. Water level and tidal current velocity were measured over a continuous 40-day period, covering three spring tides and two neap tides.

50. In addition to the new data collection, a range of information sources is available, including:

- Marine Renewable Atlas (BERR, 2008);
- National Tide and Sea Level Facility (British Oceanographic Data Centre);
- Extreme sea levels database (Environment Agency, 2015);
- United Kingdom Hydrographic Office (UKHO) tidal diamonds;
- National Oceanographic Laboratory Class A tide gauges;
- United Kingdom Climate Projections 2018 (UKCP18);
- British Geological Survey 1:250,000 sea bed sediment mapping; and
- Admiralty Charts and United Kingdom Hydrographic Office survey data.

7.6. EXISTING ENVIRONMENT

7.6.1. Bathymetry

51. Water depths across the MDZ and export cable corridor vary between approximately -2 m CD at the landfall and 72 m CD in the northwest part of the MDZ (**Figure 7-1, Volume II**) (Partrac, 2018). The average depth across the MDZ is approximately 40 m.

52. Most of the sea bed comprises large areas of outcropping bedrock with minimal relief above surrounding bed levels (**Figure 7-3, Volume II**). Secondary bathymetric features include a large, generally symmetric, sand ridge north of South Stack which extends to the northwest for approximately 1 km (within the offshore cable corridor) (**Plate 7-1**). The crest of the ridge is about 8 m to 10 m higher than the surrounding sea bed. Several smaller ridges oriented parallel to the main ridge occur to its north-northeast.

53. Within Abraham's Bosom (a bay towards the landfall), the bathymetry is smoother, representing the surface of an area of sediment on top of the bedrock, bounded by rock outcrops to the north and south.

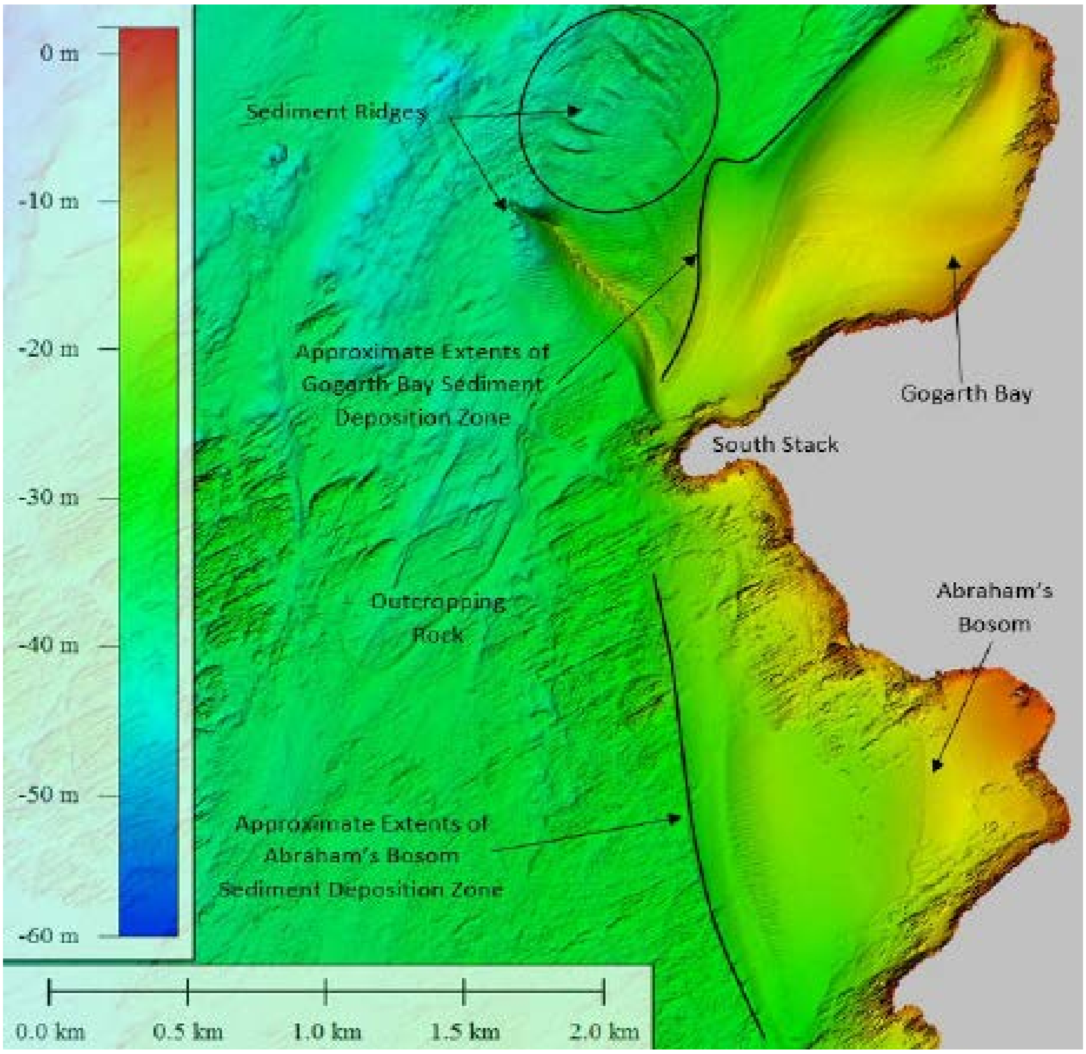

Plate 7-1 Bathymetric Features Close to Shore Within the Offshore Cable Corridor (Partrac, 2018)

54. At a more local scale the sea bed is uneven due to the presence of bedforms of various sizes. Megaripples occur close to Abraham’s Bosom within the offshore cable corridor. They are up to 0.6 m high, up to 12.8 m wavelength, with crests oriented approximately west-east, indicative of north-south tidal currents (**Plate 7-2**). Larger fields of megaripples occur in the south and southwest parts of the MDZ, where they are up to 0.6 m high, up to 12.9 m wavelength, with crests oriented approximately west-east.

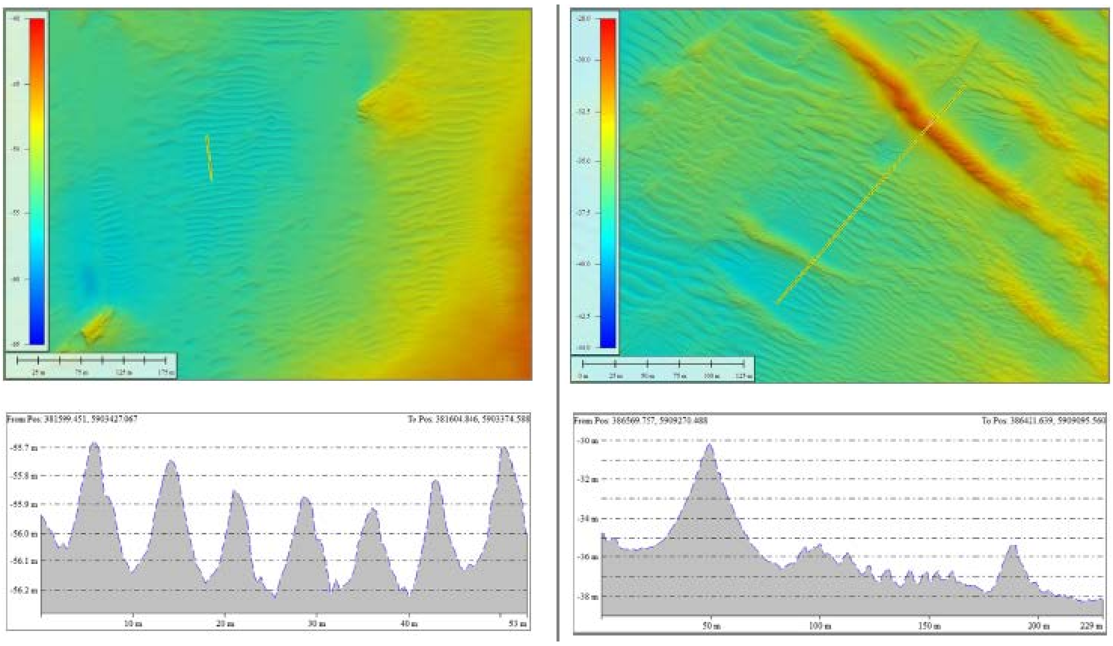

Plate 7-2 Examples of Megaripples in Deeper (left) and Shallower (right) Water

7.6.2. Offshore Geology

55. The geology of the MDZ is dominated by bedrock at, or very close to, the surface, which was not differentiated by Partrac (2018). However, it was postulated that it forms part of the Mona Complex that is exposed across Anglesey, and Holy Island specifically. The bedrock is covered with a sediment veneer composed of gravel and boulders ranging in size from 0.2 m to 1.5 m.

56. Across the west and southwest parts of the MDZ, the bedrock surface dips beneath the sea bed and is covered by undifferentiated ‘overburden’ (possibly glacial diamicton), up to 29 m thick in the southwest and up to 14 m in the west (**Plate 7-3**). Towards the shoreline and approaching Abraham’s Bosom bay, bedrock is overlain by up to 7 m of sediment and then 2 – 4 m of sediment within the bay itself (likely to be mainly sand) (**Plate 7-4**).

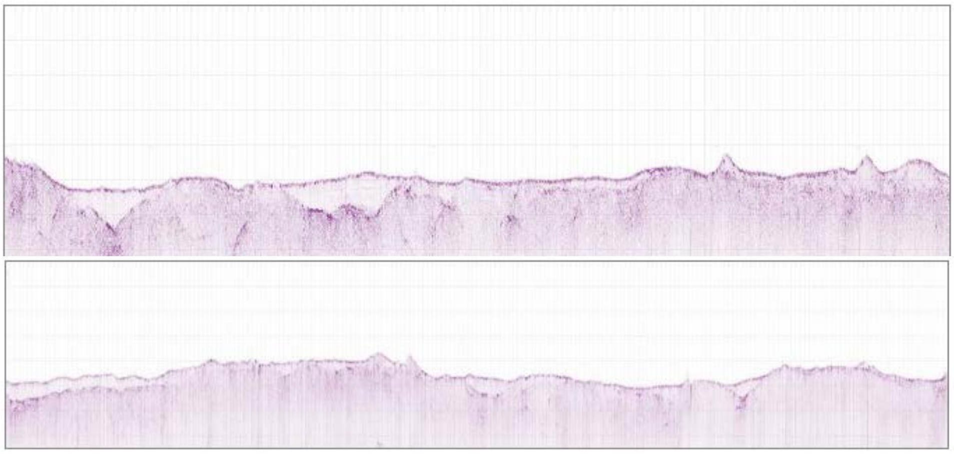

Plate 7-3 Example North-South Aligned Western MDZ and Buffer Zone Sub-Bottom Profiles Showing Overburden on Top of Bedrock (Partrac, 2018)

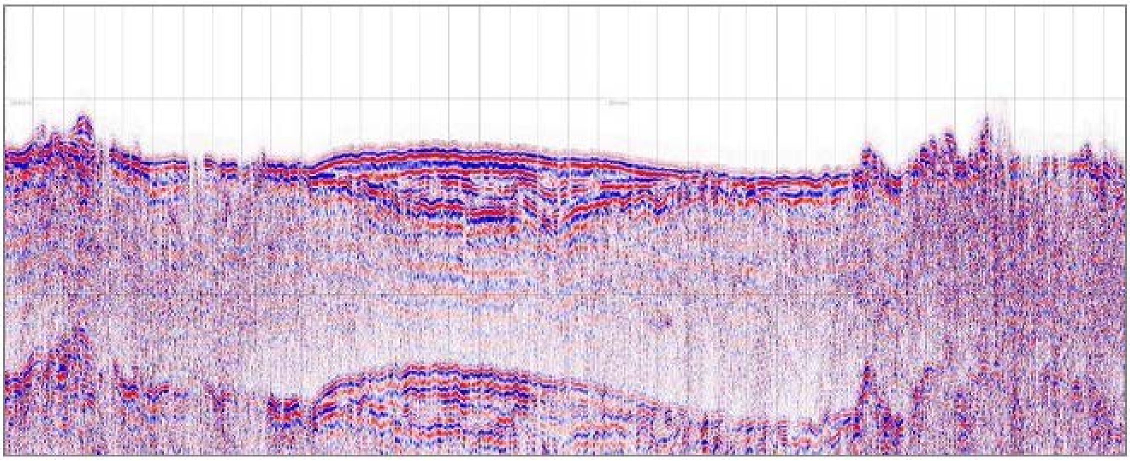

Plate 7-4 Example South (left of the image) to North (right of the image) Sub-Bottom Profile Across the Entrance to Abraham's Bosom Showing Deposition on Top of Bedrock (Partrac, 2018)

7.6.3. Tidal Water Levels

57. Tidal water levels within the MDZ are characterised by the ADCP surveys from Sites 1 and 2 in **Figure 7-4** (**Volume II**) which describe a typical spring tidal range of around 4.5 m and a typical neap tidal range of around 3.0 m (**Plate 7-5**).

58. Tidal water levels at the landfall are best represented by tidal data from the standard port of Holyhead, which are shown in **Table 7-11**. This shows a typical spring tidal range of around 4.9 m and a typical neap tidal range of around 2.4 m.

Table 7-11 Tidal Levels at Holyhead (source: Admiralty Tide Tables 2019)

Parameter	Water Level (m CD)	Water Level (m ODN)
Lowest astronomical tide (LAT)	0.00	-3.05
Mean low water springs (MLWS)	0.70	-2.35
Mean low water neaps (MLWN)	2.00	-1.05
Mean sea level (MSL)	3.30	0.25

Parameter	Water Level (m CD)	Water Level (m ODN)
Mean high water neaps (MHWN)	4.40	1.35
Mean high water springs (MHWS)	5.60	2.55
Highest astronomical tide (HAT)	6.30	3.25

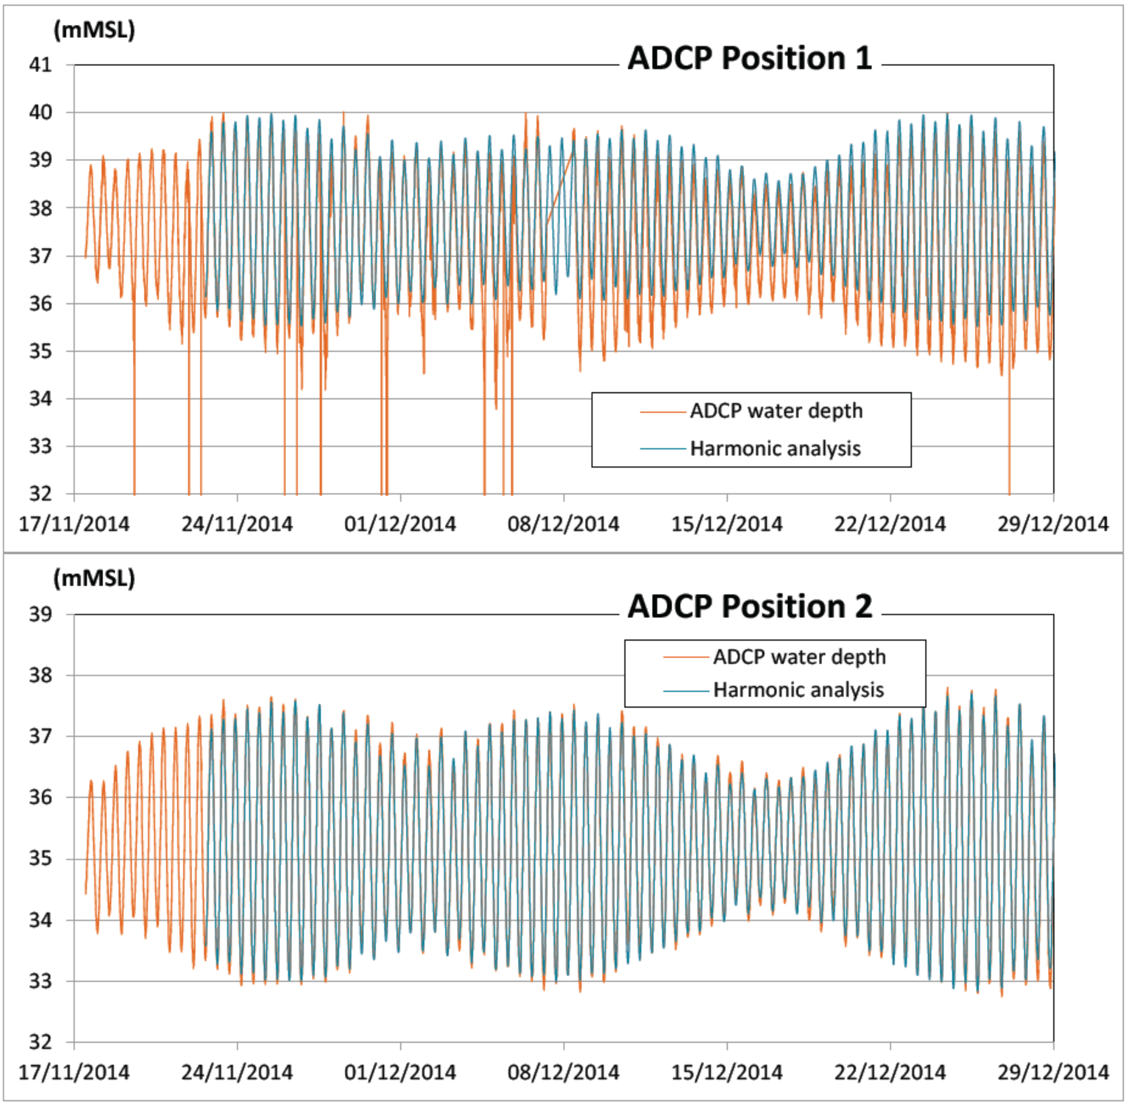

Plate 7-5 Tidal Levels at Sites 1 and 2 within the MDZ (source: HR Wallingford 2017)

7.6.3.1. Storm Surge

59. The tidal water levels described above are astronomically driven and thus are regular and predictable, but these can be elevated or supressed by meteorological events, such as storms and surges. **Table 7-12** presents the extreme sea levels that can be attained at Holyhead for different return period events due to these surge effects. The tidal currents can also become enhanced by positive storm surges, and these effects are implicit within measured tidal current data in the following section.

Table 7-12 Extreme Sea Levels at Holyhead (source: McMillan *et al.*, 2011)

Return Period of Surge Event	Level (m CD)	Level (m ODN)
1 in 1 year	0.31	3.36

Return Period of Surge Event	Level (m CD)	Level (m ODN)
1 in 10 years	0.56	3.61
1 in 50 years	0.72	3.77
1 in 100 years	0.78	3.83
1 in 200 years	0.84	3.89

7.6.4. Tidal Currents

60. Tidal currents within part of the MDZ are characterised by the ADCP surveys from Sites 1 and 2 (**Table 7-13**). These data show that current velocities at the measurement locations are slightly lower towards the sea bed due to bed-friction, but all values recorded exhibit very high baseline current speeds.

Table 7-13 Peak Tidal Currents at Sites 1 and 2 within the MDZ (source: OpenHydro, 2015)

Height above sea bed	Peak Velocities on a Mean Spring Tide Site 1 (m/s)	Peak Velocities on a Mean Spring Tide Site 2 (m/s)
10 m	2.71	2.64
15 m	2.84	2.79
20 m	2.92	2.90

61. The current roses shown in **Figure 7-4** (**Volume II**) **Plate 7-2** indicate that at both Sites 1 and 2, the baseline current velocities are strongly aligned from just east of south to north-northwest. However, further north in the MDZ, the tidal currents flow around Holy Island (to the north on a flooding tide and to the south on an ebbing tide) along a more south-north and then (with progression north) south-southwest-north-northeast axis.

62. Tidal current speeds and directions were predicted by the baseline numerical modelling undertaken by HR Wallingford (2017). **Figure 7-5** (**Volume II**) shows the peak depth-averaged flow velocities for a mean spring tide. Peak speeds are generally faster through the eastern parts of the subzones, reaching around 2.6 – 2.8 m/s in most areas, apart from the northernmost and southernmost subzones. The highest velocities within the MDZ are recorded just off Holy Island (4.0 m/s). For the western parts of the subzones, peak speeds are lower, reaching around 2.2 – 2.6 m/s.

7.6.5. Waves

63. Given the semi-enclosed nature of the Irish Sea, most oceanic swell waves are prevented from reaching the Anglesey coastline through St George’s Channel and from the north due to the shelter provided by the Isle of Man. As a result, waves arriving at the Anglesey coastline are predominantly wind generated within the Irish Sea (Royal HaskoningDHV, 2011). The fetch between Ireland and Wales is generally less than 100 km, limiting the height that waves can grow from the west. The largest fetch originates from a southwest direction, where the fetch can reach thousands of kilometres into the Atlantic Ocean.

64. Wave exposure at Holy Island is extremely variable owing to the range of coastline orientations. Most of the Anglesey coast is west facing and dominant offshore waves arrive as swell waves travelling up the Irish Sea from the south-southwest and southwest. Exposure to waves

increases towards Holy Island due to decreasing shelter provided by the Llyn Peninsula. Towards the north of the Anglesey coast, offshore waves arrive predominantly from the west and occasionally from the north to northeast.

65. The wave regime was characterised using data obtained from the Met Office at three locations northwest of the MDZ (**Figure 7-6, Volume II**). Results show the dominant offshore wave direction for all three locations is south-southwest to southwest. The wave rose from the most western point offshore (A) also shows waves from a northerly and southerly direction occurring relatively frequently. Moving eastward (B and C), these waves become less frequent due to the shelter provided by Wales to the south and the Isle of Man to the north.

66. Annual mean significant wave height (SWH) for the area is 1.26 – 1.50 m, ranging from 0.76 – 1.00 m in the summer to 1.51 – 1.75 m in the winter (ABPmer, 2008).

7.6.6. Climate Change

67. Historical data show that the global temperature has risen significantly due to anthropogenic influences since the beginning of the 20th century, and predictions are for an accelerated rise, the magnitude of which is dependent on the magnitude of future emissions of greenhouse gases and aerosols.

68. As a result of future global warming, sea-level is predicted to rise at accelerated rates. The latest available science of projected sea-level rise is available from the UK Climate Projections 2018 (UKCP18). **Table 7-14** presents projections of sea level rise to 2050 (relative to 2018) under three Representative Concentration Pathways (RCPs) (Met Office, 2018).

Table 7-14 Sea level Rise Projections to 2050 with 5th, 50th and 95th Percentile Confidence Intervals (Met Office, 2018)

Representative Concentration Pathway (RCP)	Year	UKCP18 projected increase in sea level (m relative to 2018 values)		
		5th percentile	50th percentile	95th percentile
RCP 2.6	2050	0.071	0.117	0.180
RCP 4.5	2050	0.084	0.132	0.201
RCP 8.5	2050	0.108	0.168	0.246

69. As the indicative design life of the Project is 37 years, and both onshore and offshore infrastructure is set far enough from the coast, the projected increases in sea level to 2050 will not change significantly through the design life of the Project.

70. Climate change will also affect extreme sea levels. **Table 7-15** presents projections of sea level rise to 2050 (relative to 2018) under three RCPs (Met Office, 2018).

71. Different methods were used for analysis of present-day extreme water levels and future projections under UKCP18, and the former is currently being updated by the Environment Agency with a scheduled release for the update in 2019. It is notable that the three projections of future extreme sea levels do not show marked increases relative to each other and the effects over the life of the development are modest and can be adequately accounted for in design.

Table 7-15 Extreme Sea Levels at Holyhead (source: McMillan *et al.*, 2011)

	Extreme Sea Level (mODN)			
Return Period of Surge Event	**Present Day (2018(**	**2050 (RCP2.6) (50 percentile)**	**2050 (RCP4.5) (50 percentile)**	**2050 (RCP8.5) (50 percentile)**
1 in 1 year	3.36	3.48	3.50	3.53
1 in 10 years	3.61	3.74	3.75	3.79
1 in 50 years	3.77	3.91	3.92	3.96
1 in 100 years	3.83	3.99	4.00	4.03
1 in 200 years	3.89	4.06	4.07	4.11

73. With respect to waves, climate projections from UKCP18 indicate that at Holyhead mean significant wave heights will decrease under all but one modelled scenario by between 0 – 20 % by 2100 (although under one scenario they could increase by up to 30 %). Annual maximum wave heights at Holyhead could increase or decrease by up to 20 % by 2100 depending on modelled scenario (Palmer *et al*., 2018). These results demonstrate the uncertainty inherent in projecting changes in future wave climate associated with climate change.

7.6.7. Sea Bed Sediment Distribution

7.6.7.1. MDZ

74. Partrac (2018) used side-scan sonar to provide a general overview of the sea bed sediment distribution across the MDZ. Throughout most of the northern, central and eastern parts of the MDZ the sea bed is dominated by outcropping bedrock with thin patches of sandy gravel, whereas the deeper western part comprises relatively uniform gravel or gravelly sand.

75. Only one sea bed sediment sample (location 41) was recovered from the MDZ, on its eastern boundary, northwest of South Stack (Ocean Ecology, 2018). Two samples were collected in the buffer zone, one north of South Stack (location 15) and one to the south of the MDZ (location 20). The particle size characteristics of these three samples are presented in **Plate 7-6** and **Table 7-16**. The dominant sediment type in sample 41 is gravel (73 %) with 27 % sand, with a median particle size of about 3.8 mm. In samples 15 and 20, the dominant component is sand (89-93 %) with a median particle size of 0.63 mm and 0.75 mm (both coarse sand).

Table 7-16 Particle Size Characteristics of Sea Bed Sediment Samples in the MDZ and Buffer Zone. Data from Ocean Ecology (2018)

Station	Gravel (%)	Sand (%)	Mud (%)	d_{50} (mm)
41	73	27	0	3.8
15	9	89	2	0.63
20	7	93	0	0.75

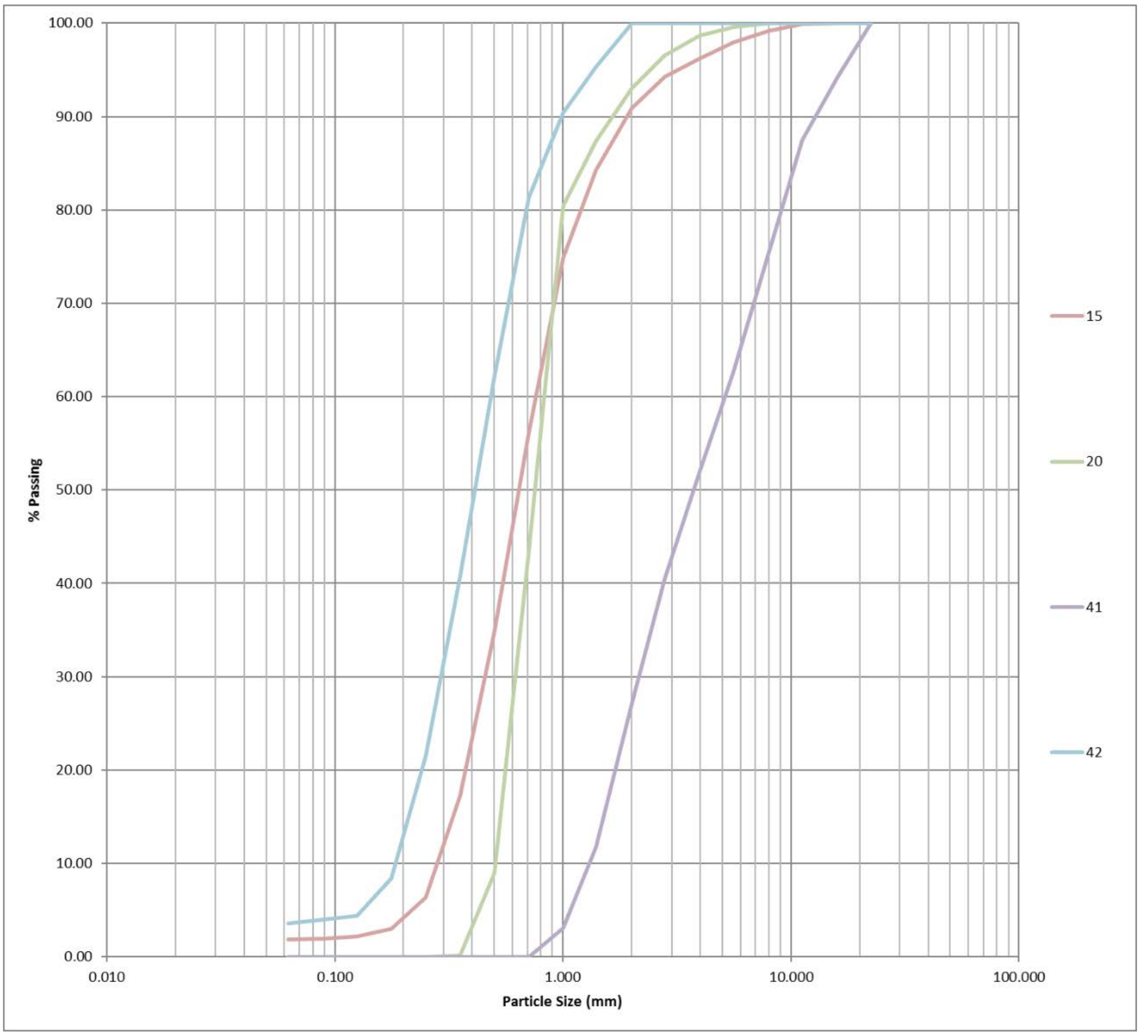

Plate 7-6 Cumulative Particle Size Distribution Curves for the Four Seabed Sediment Samples. Data from Ocean Ecology (2018)

7.6.7.2. Export Cable Corridor

76. One sample (42) was collected along the landward part of the offshore cable corridor in Abraham's Bosom (Ocean Ecology, 2018). The particle size characteristics of this sample is presented in **Plate 7-6** and **Table 7-17**. The dominant sediment size is sand (96 %) with a median particle size of about 0.41 mm (medium sand). This sample falls within the Abraham's Bosom sediment deposition zone identified by Partrac (2018) (**Plate 7-1**).

Table 7-17 Particle Size Characteristics of the Sea Bed Sediment Sample in the Offshore Cable Corridor. Data from Ocean Ecology (2018)

Station	Gravel (%)	Sand (%)	Mud (%)	d_{50} (mm)
42	0	96	4	0.41

7.6.8. Bedload Sediment Transport

77. Sediment transport pathways within the MDZ and across the offshore cable corridor have been analysed using the orientation and asymmetry of bedforms. The orientation of sand ridges and megaripples indicate that gross sediment transport is to the north and south to the south of South Stack and then bends to the northeast and southwest to the north of South Stack. The

size and shape of the bedforms makes it difficult to determine a long-term net transport direction as they are generally symmetric and change their geometry on different states of the tide (Partrac, 2018).

78. Previous studies show that regional sediment transport is north to northeast (BGS, 2005). Littoral drift is very weak because of shoaling within bays and diffraction around headlands along the Anglesey coastline and so sediment is contained within pockets between headlands (Royal HaskoningDHV, 2011). If longshore currents exist, they usually decrease as they transport sediment towards one side of the bay, as the beach rotates to face incoming waves (Royal HaskoningDHV, 2011).

7.6.9. Suspended Sediment Transport

79. Measurements of suspended sediment concentration were carried out generally across the Irish Sea during June and November 1997, and April and September 1998 at a total of 85 stations. Overall, suspended sediment concentrations were between 2.55 and 23 mg/l over the period (**Table 7-18**), although concentrations varied seasonally (Bowers *et al*., 2002).

Table 7-18 Concentration of Total Suspended Solids (mg/l) in the Irish Sea 1997 - 1998

	Min	Max	Mean
June 1997, 16 stations	3.73	14.18	6.57
November 1997, 17 stations	2.55	20.38	9.82
April 1998, 26 stations	3.30	23.00	10.27
September 1998, 26 stations	2.76	17.18	5.70

80. More specific to the sea bed off Anglesey, several authors have described an Anglesey Turbidity Maximum (ATM) based on observations from space (Simpson and Brown, 1987; Weeks and Simpson, 1991; Bowers *et al*., 1998) and ships (Mitchelson, 1984; Weeks, 1989, Bowers *et al*., 2002). This is an isolated area of enhanced turbidity that is geographically fixed and present all year, although more strongly marked in winter.

81. The position of the maximum coincides with the area of high tidal currents off the northwest coast of Anglesey and its continued presence has been described as “a puzzle” (Bowers *et al*., 2005). Indeed, the phenomenon is not easy reproduced by models and there is no obvious source of sediment, since the local (and surrounding) sea bed is largely comprised of bare rock with occasional boulders. Despite being defined by authors as a “turbidity maximum”, it is only defined in this context because suspended sediment concentrations are of the order of 2 – 3 times those of the surrounding sea bed (i.e. it is a maximum *relative* to surrounding areas). In *absolute* terms, suspended sediment concentrations remain very low, reaching about 5 mg/l in summer and 10 – 15 mg/l in winter. Beyond the ATM, background suspended sediment concentrations are about 3 – 4 mg/l (Ellis *et al*., 2008).

7.6.10. Geology and Coastal Processes at the Landfall

82. The geology of the landfall comprises steep cliffs and shore platforms composed of bedded turbiditic sandstones and mudstones of the Cambrian-Ordovician South Stack Formation (of the Holy Island Group) overlain by a thin layer Quaternary diamicton (**Plate 7-7**). The bay is studded

with very small pocket beaches in enclosed sub-bays composed of shingle and occasional areas of sand (Ocean Ecology, 2018) (**Plate 7-8**).

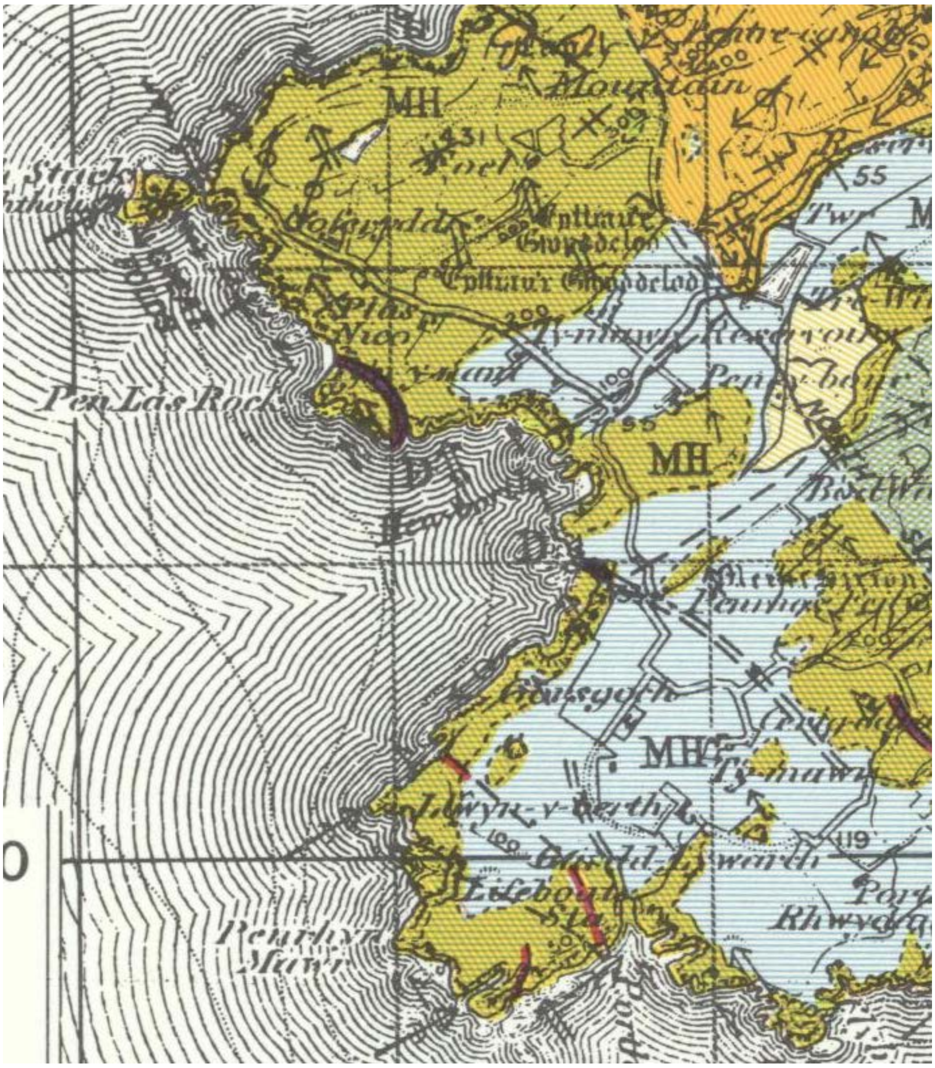

Plate 7-7 Bedrock and Quaternary Geology of the Landfall (British Geological Survey, 1974)

Plate 7-8 Photos of the cable landfall point at Abraham's Bosom (Partrac, 2018)

83. Although the west coast of Holy Island is exposed to significant wave action from the southwest, the strength of the cliffs (Cambrian-Ordovician rocks) at the landfall means that they are subject to only minor erosion.

7.7. POTENTIAL IMPACTS AND EFFECTS

7.7.1. Impact Receptors

84. The principal receptors with respect to metocean conditions and coastal processes are those features with an inherent geological or geomorphological value or function which may potentially be affected by the Project. Protected sites that could be potentially impacted by the Project include national SSSIs which underpin international SACs and Special Protection Areas (SPAs) along the coast of Holy Island. The Holy Island coast is also a Heritage Coast and part of the larger Anglesey AONB. No marine designations are within the boundaries of the Project or within a metocean or coastal processes impact pathway.

85. The potential impacts on metocean conditions and coastal processes are considered for three receptors. The specific features defined within these receptors as requiring assessment are listed in **Table 7-19** and shown in **Figure 7-7** (**Volume II**).

Table 7-19 Metocean and Coastal Processes Receptors Relevant to the Project

Receptor (Plate 7-1)	Extent of coverage	Description of features	Distance from the Project
Holy Island Coast SSSI / SAC	Holyhead West Breakwater to Cymyran Bay	Vegetated sea cliffs	Designation covers cable landfall point
Anglesey AONB	Holyhead Mountain to Cymyran Bay	Cliffs, coves and gravel beaches	Designation covers cable landfall point
Holyhead Mountain Heritage Coast	Holyhead Mountain to Cymyran Bay	Cliffs, coves and gravel beaches	Designation covers cable landfall point

86. This section assesses the significance of potential impacts on the wave and/or current and/or sediment transport regimes on the receptor groups.

7.7.1.1. Holy Island Coast SSSI / SAC

87. The west coast of Holy Island including the landfall is composed of rock cliffs which support important examples of coastal cliff heathland vegetation. In addition to maritime heath, there are extensive maritime cliff-crevice and grassland communities.

7.7.1.2. Anglesey AONB

88. The main features of the Anglesey AONB are undeveloped cliffs (including North and South Stack) alternating with coves and gravel beaches (many within Abraham's Bosom bay and the landfall).

7.7.1.3. Holyhead Mountain Heritage Coast

89. The AONB designation is supported by the non-statutory designation of the Holyhead Mountain Heritage Coast.

7.7.2. Effects

90. In addition to the receptor groups listed in **Table 7-19** there are other potential changes (effects) to metocean conditions and coastal processes associated with the Project which may manifest themselves as impacts upon a wider grouping of receptors. These include marine sediment and water quality, benthic and intertidal ecology, fish and shellfish ecology, offshore archaeology and commercial fisheries.

91. In respect of these effects, the assessment only defines the magnitude of change in metocean conditions or coastal processes. The assessments of the significance of impacts arising from these effects or changes on other receptors are made within the relevant chapters of this ES pertaining directly to those receptor types (**Chapter 8, Marine Water and Sediment Quality**, **Chapter 9, Benthic and Intertidal Ecology**, **Chapter 10, Fish and Shellfish Ecology**, **Chapter 13, Offshore Archaeology** and **Chapter 14, Commercial Fisheries**).

7.7.3. Mitigation Measures

7.7.3.1. Embedded Mitigation

92. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the Project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process.

93. A range of different information sources has been considered as part of embedding mitigation into the design of the Project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

94. The embedded mitigation relevant to metocean conditions and coastal processes includes;

- Devices within the MDZ will be spaced appropriately to minimise the energy loss between adjacent rows. This also has the added advantage of causing least potential impact on the baseline tidal current regime.
- So far as other constraints (for example, Chapter 24, Chapter Seascape, Landscape and Visual Impact Assessment) allow, devices within the MDZ are most likely to be placed towards the eastern part of the MDZ, where the baseline tidal currents are higher. This means that any suspended sediment effects will be more rapidly and more widely dispersed than if devices were to be placed towards the west of the MDZ.

7.7.3.2. Additional Mitigation Measures

95. An outline Construction Environmental Management Plan (CEMP) (**Document MOR/RHDHV/DOC/0073**) and outline Pollution Prevention and Management Plan (PPMP) (**MOR/RHDHV/DOC/0077**) will be submitted with the TWAO application and Marine Licence application. The development of the detailed design will refine the worst-case impacts assessed in this EIA. It is recognised that construction mitigation is an important element in the management and verification of the actual Project impacts. The outline CEMP and PPMP would be agreed with NRW prior to construction works commencing.

7.7.4. Worst-Case Scenarios

96. The offshore project area consists of the offshore cable corridor with landfall at Penrhos Feilw and the Project within the MDZ. Their detailed designs (including numbers of devices, layout configuration, requirement for scour protection etc.) will not be determined until after the TWAO has been determined. Therefore, realistic worst-case scenarios in terms of potential impacts/effects on metocean conditions and coastal processes are adopted to undertake a precautionary and robust impact assessment. The realistic worst-case scenarios used are described in the sections below.

97. To achieve the maximum 240 MW export capacity, there would be up to 620 devices, supporting up to 1,648 Tidal Energy Convertors (TECS) and up to 740 inter-array cables within the MDZ. This represents the worst case scenario as outlined in **Chapter 4, Project Description**. In addition, numerous electrical hubs that aggregate the power to transmit along the offshore cable are considered as part of the worst-case scenario, as well as navigation marker buoys, environmental monitoring platforms and ADCPs, all of which will also interact with the seabed. The hubs could include a combination of fully submerged sea bed mounted (up to 120), floating (up to 93) and sea bed mounted and surface emergent (up to eight).

98. For the purpose of defining impact assessment parameters for the repowering phase, an assumption has been made that 50% of the tenants will undertake repowering, i.e. for 50% of the tenants, their infrastructure will be removed and replaced (potentially with different infrastructure by a different tenant). For the other 50% of tenants, their infrastructure will remain over the lifetime of the project.

99. In terms of impact assessment parameters, the repowering process has been defined as per below:

- Initial temporary seabed disturbance via deployment of barge anchors to remove foundations, TEC's, hubs, inter-array cables and monitoring equipment for 50% of the Tenants (berths); and
- Further temporary seabed disturbance via re-installation (repowering) of foundations, TEC's, hubs, inter-array cables and monitoring equipment for the same 50% of Tenants (berths).

100. The export cables and export cable tails would not be removed as part of the repowering phase

101. As the repowering phase will involve both the removal and installation of infrastructure, the types of effects on metocean conditions and coastal processes would be analogous to those identified for the construction and decommissioning phase and therefore is considered within **Section 7.7.5** and **Section 7.7.7**, where relevant. However, note that repowering will occur during the 37-year operation of the Project.

7.7.4.1. Foundations

102. Within the Project, several different types of foundation types for the devices and hubs are being considered, as described in **Chapter 4, Project Description**, these include:

- Monopiles or jacket (on pin piles): the piling method would be dependent on the nature of the sea bed. Although piles can be hammered into soft sea bed types using percussive piling, such an approach is not appropriate in areas of predominantly hard sea bed such as the MDZ. In such locations rock sockets may be pre-drilled and grouted pin piles, or screw piles may be used to anchor the foundation;
- Gravity base structures (GBS): if piling and drilling into hard sea bed types would be technically challenging, there is also the potential for gravity base structures to be used. These would consist of bases (concrete, steel or iron) attached to a jacket foundation, acting as feet on the jacket structure);
- Catenary floating devices: catenary moorings may require up to four gravity anchors. These anchors tend to weigh in the region of 300 tonnes. Mooring lines are attached to the anchors to hold the device support structure in place. Gravity foundations for larger floating platforms may be up to 2000 tonnes in weight, with a footprint of up to 312 m^2; and
- Tension floating devices: a tensile mooring system may be used to reduce movement. These are typically deployed using four anchor points and kept under tension, as opposed to the catenary mooring system which is not held under tension.

103. Due to the high energy dynamic environment of the MDZ, with associated limited superficial sediment cover on the sea bed, it is assumed that the need for scour protection will be minimal.

104. The layout of the tidal devices would be defined post consent but would be based on deployed capacity of up to 240 MW plus hubs. The total number of devices within the MDZ will be dependent on the individual generating capacity of the devices being installed. The site may be divided into eight subzones, with the zones allowing the demarcation of different technology types.

7.7.4.2. Cable Installation

7.7.4.2.1. Inter-Array and Offshore Cables

105. Inter-array cables would link individual devices within an array to a singular point (hubs), where output from all the devices is collected prior to exporting via the offshore cable. Up to 204.5 km of inter-array cables may be installed on the sea bed. Individual inter-array cables would be up to 2.5 km long with a total sea bed footprint of up to 30, 040 m^2 (including rock bag cable protection).

106. Up 40.5 km of offshore cables will be installed, one from each of the tidal arrays in each sub-zone (not including inter-array cables). The location of the offshore cable corridor is shown on **Figure 1-1** (**Volume II)**. Individual offshore cables would be between 1.2 km and 6 km long with a total sea bed footprint of about 11,745 m^2 (including split-pipe cable protection).

7.7.4.2.2. Cable Protection

107. Cables would be free laid with protection at locations along their lengths. For most of their length, no trenching will be required, although it is possible that some post-installation jetting may be needed to bury the cable across the sand wave feature in the northern half of the cable corridor.

108. The following cable protection options may be used and this would be determined during the final design of the Project:

- Rock (bags) placement - the laying of rocks on top of the cable; and
- Concrete mattresses - prefabricated flexible concrete coverings that are laid on top of the cable. The placement of mattresses is slow and as such is only used for short sections of cable.

109. It is assumed on a worst-case scenario that up to 270 individual rock bags or concrete mattresses (18 m^2 each) could be used on the export cables. This is additional to the split-pipe protection referenced in **Section 7.7.4.2.1** above.

7.7.4.2.3. Cable Burial

110. There is a significant sand wave feature located in the northern half of the offshore cable corridor. It is likely that cables will be installed over this after which an as-laid survey would be completed to identify any areas where the cable is in suspension to target any necessary remedial work at that time. The sand wave can be reduced using a mass flow excavator or dredger. The spatial extent of the sandwave covers an estimated 27,258 m^2.

7.7.4.2.4. Boulder Clearance

111. Pre-construction surveys will identify any requirement for boulder clearance within the offshore project area. Boulder clearance would involve localised relocation of boulders which would have no overall impact on metocean and coastal processes and is therefore not considered further.

7.7.4.2.5. Pre-lay Grapnel Run

112. A pre-lay grapnel run would be undertaken to clear any identified debris in advance of each phase of installation. The maximum width of sea bed disturbance along the pre-grapnel run would be 20 m. This is encompassed by the maximum footprint of cable installation works associated with ploughing (30 m disturbance width).

7.7.4.3. Landfall

113. The offshore cable landfall would be at Penrhos Feilw using either Horizontal Directional Drilling (HDD) (preferred) or use of ducts or J-tubes pinned to the cliff and/or laid in a shallow trench or slot.

114. A HDD landfall would comprise the following components:

- Up to nine cable tails each up to 620 m long at the landfall;
- Up to nine separate drills, each up to 550 m long;
- Separation of 20 m between HDD exit points; and
- Total drill cuttings volume of up to 900 m^3 for HDD alone (total amount for all nine drills).

115. A trenched landfall would comprise the following components:

- Up to nine cable tails each up to 620 m long at the landfall;

- Up to nine separate shallow trenches (with slots within the cliff face) from the intertidal zone to the transition pits, each up to 740 m long;
- Individual trench width would be up to 600 mm with approximately 0.5 m separation distances or a single trench approximately 10 m wide and 0.5 m to 1.2 m deep, with all nine cables laid within it;
- Total material removed would be approximately 8,880 m^3. The majority would be replaced to backfill the trench after the ducts / cables have been installed; and
- Duct or split pipe over 370 m to 550 m of each cable, up to 350 mm external diameter.

7.7.4.4. Construction Programme

116. The construction of offshore works (for installation of tidal devices and associated cabling and infrastructure) would be phased over a period of several years, taking up to 15 days per device or hub and up to 1.5 days for each inter-array cable, up to 20 days for each offshore cable, and up to 12 days for each phase of cable protection. Up to nine separate cable laying and protection campaigns are possible. **Table 7-20** provides an indicative construction programme for the Project.

Table 7-20 Worst-Case Project Construction Programme Based on 240 MW Deployment

Indicative Programme	Approximate Duration (per event)	Approximate Duration (full 240 MW capacity)
Foundations and devices (including drilling of up to 3 days per device – maximum of 596 devices[2])	15 days	4,306 days
Hub installation vessel days (per hub – 120 hubs)	15 days	1,800 days
Inter-array cable vessel days (per cable – 740 cables)	1.5 days	1,110 days
Export cables vessel days (per cable – 9 cables)	20 days	180 days
Export cable Protection (per cable – 9 cables)	12 days	108 days

7.7.4.5. Operations and Maintenance

7.7.4.5.1. Devices

117. Regular maintenance of the devices will be required during operation. These works will have minimal impact on metocean conditions and coastal processes. However, the placement of anchors or jack-up vessels during maintenance activity has been considered to provide a comprehensive assessment. A maximum average of two turbine locations per day, visited by a jack-up vessel has been assessed, to cover 15 inspections of each device annually (for both planned and unplanned maintenance activities).

7.7.4.5.2. Cable Repairs

118. It is expected that once installed, the ongoing offshore operations for the offshore cables would be limited to inspection (through survey) and maintenance of the cables and ancillaries. It is

[2] Based on a worst-case installation scenario of a full 240 MW deployment of pin-piled anchors

anticipated that up to ten major cable repairs (five days each) may be required throughout the Project life. It is assumed that up to 750 m of cable would be subject to repair works per event (7,500 m in total). These will involve the same type of sea bed disturbance as experienced during the main cable installation phase. However, any such disturbance would be more temporally and spatially limited. Annual inspections will be carried out for the first three years, reducing to two years thereafter.

119. In most cases a cable failure would lead to the following operation:

- Vessel anchor placement;
- Cutting the cable;
- Lifting the cable ends to the repair vessel;
- Jointing a new segment of cable to the old cable; and
- Lowering the cable (and joints) back to the sea bed.

7.7.4.6. Summary

120. **Table 7-21** describes the relevant worst-case scenarios for metocean conditions and coastal processes.

Table 7-21 Summary of Worst-Case Scenarios for the Project

Impact	Parameter	Worst-case	Rationale
Construction and Repowering			
Changes in suspended sediment concentrations due to foundation installation in the Project	Sediment plume created by foundation installation	Monopiles / jackets with pin piles	Greatest volume of disturbed/released sediment
Changes in sea bed level (morphology) due to deposition during foundation installation in the Project	Sediment deposited from the plume created by foundation installation	Monopiles / jackets with pin piles	Greatest morphological change would be associated with greatest volume of disturbed/released sediment
Changes in suspended sediment concentrations during offshore export cable installation (including nearshore) (construction only)	Sediment plume created by offshore export cable installation	Placement of up to 40.5 km of cable and cable protection at locations along the length, plus post-installation jetting to bury offshore cable across the sand ridge feature in the northern half of the cable corridor	Greatest volume of disturbed/released sediment
Changes in sea bed level due to offshore export cable installation (construction only)	Changes in sea bed level due to deposition from the suspended sediment plume created during offshore export cable installation	Placement of up to 40.5 km of cable and cable protection at locations along the length plus levelling of sand ridge in northern half of the cable corridor	Greatest morphological change

Impact	Parameter	Worst-case	Rationale
Changes in suspended sediment concentrations during inter-array cable installation	Sediment plume created by inter-array cable installation	Placement of up to 204.5 km cable and cable protection at locations along the length	Greatest volume of disturbed/released sediment
Changes in sea bed level due to inter-array cable installation	Sediment deposited from plume created by inter-array cable installation	Placement of up to 204.5 km cable and cable protection at locations along the length	Greatest morphological change would be associated with greatest volume of disturbed/released sediment
Changes in sea bed level (morphology) due to indentations during installation in the Project	Indentations on the sea bed due to the physical presence of installation vessels	Jack-up and anchor footprints	Greatest morphological change would be associated with vessels working around turbines for foundation installation
Operation and Maintenance			
Changes to the tidal regime due to the presence of structures in the Project	Changes to tidal currents created by the presence of devices and hubs	Envelope covering 240 no. 1 MW devices to 620 no. smaller (0.3-0.5 MW) devices	Maximum 240 MW capacity
Changes to the wave regime due to the presence of structures in the Project	Changes to waves created by the presence of devices and hubs	GBS foundations	Of all foundation types being considered, GBS would have the greatest physical blockage effect on the baseline wave regime
Changes to the sediment transport regime due to the presence of structures in the Project	Sediment plume and changes to bedload sediment transport created by the presence of devices and hubs	GBS foundations supporting an envelope covering 240 no. 1 MW devices to 620 no. smaller (0.3-0.5 MW) devices	The greatest changes to the sediment transport regime would be caused by the greatest changes to the tidal regime and/or the greatest changes to the wave regime
Loss of sea bed morphology due to the footprint of structures in the Project	Sea bed morphology	Total footprint of 129,932 m^2	This includes the worst-case scenario of GBS foundations, drill arisings, export cable footprint (cables and protection systems), array cable footprint, additional cable protection material, cable tails, footprint of navigation marker buoys and footprint of ADCP moorings
Morphological and sediment transport effects due to cable protection measures for offshore export cables (including nearshore and at the coastal landfall)	Sea bed morphology and sediment transport along offshore cables	Total footprint of 11,745 m^2 Placement of free laid cable and rock bags and/or concrete mattresses	Greatest footprint from offshore export cables and cable protection

Impact	Parameter	Worst-case	Rationale
Morphological and sediment transport effects due to cable protection measures for inter-array cables	Sea bed morphology and sediment transport along inter-array cables	Total footprint of 30,040 m^2 Placement of free laid cable and rock bags and/or concrete mattresses	Greatest footprint from inter-array cables and cable protection
Changes in sea bed level (morphology) due to maintenance during maintenance in the Project	Cable repairs and maintenance vessel footprints	Turbine maintenance – jack-up and anchor footprints from a maximum two turbine locations visited per day Cable repairs – a maximum of ten cable repairs (five days each)	Greatest morphological change would be associated with vessels working around turbines for foundation maintenance and for repairs of cables
Decommissioning and Repowering			
Changes in suspended sediment concentrations due to device and hub removal	Suspended sediment concentrations	GBS removal	Greatest volume of disturbed/released sediment would be with removal of GBS since monopiles/pin piles would be cut-off at sea bed level
Changes in sea bed level due to device and hub removal	Sea bed morphology	GBS removal	Greatest morphological change would be associated with greatest volume of disturbed/released sediment
Changes in suspended sediment concentrations during offshore export cable removal (including nearshore and at the coastal landfall) (decommissioning only)	Suspended sediment concentrations	Removal of up to 204.5 km of cable and cable protection at locations along the length	Greatest volume of disturbed/released sediment (compared to leaving *in situ*)
Changes in sea bed levels due to removal of the offshore export cables (decommissioning only)	Sea bed morphology	Removal of up to 204.5 km of cable and cable protection at locations along the length	Greatest morphological change would be associated with greatest volume of disturbed/released sediment (compared to leaving *in situ*)
Changes in suspended sediment concentrations during removal of parts of the inter-array cables	Suspended sediment concentrations	Removal of up to 40.5 km of cable and cable protection at locations along the length	Greatest volume of disturbed/released sediment (compared to leaving *in situ*)
Changes in sea bed levels due to removal of parts of the inter-array cables	Sea bed morphology	Removal of up to 40.5 km of cable and cable protection at locations along the length	Greatest morphological change would be associated with greatest volume of disturbed/released sediment (compared to leaving *in situ*)

Impact	Parameter	Worst-case	Rationale
Changes in sea bed level (morphology) due to indentations during decommissioning in the Project	Indentations on the sea bed due to the physical presence of decommissioning vessels	Jack-up and anchor footprints	Greatest morphological change would be associated with vessels working around turbines for foundation removal

7.7.5. Potential Impacts During Construction and Repowering

7.7.5.1. Impact 1: Changes in Suspended Sediment Concentrations During Foundation Installation in the Project

121. During the construction phase there is potential for foundation installation activities within the Project to disturb sediments, either from the sea bed surface or from below the sea bed (depending on foundation type) and release them into the water column as a plume. This will enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments settle once again on the sea bed.

122. The principal causes of disturbance during foundation installation would be:

- Preparatory works for foundation installation, including boulder clearance;
- Placement of bed-mounted GBS foundations on the sea bed;
- Installation of anchor points for floating systems; and
- Pre-drilling of rock sockets for piled foundations (e.g. monopiles or pin piles).

123. Throughout the MDZ, there is a paucity of surface sediment, with tide-swept bedrock prevailing. Where sediment does exist in these areas, it is sparse, and predominantly gravel, cobbles and rock boulders, which are not particle sizes that can be suspended in the water column and therefore will not form part of a sediment plume even if disturbed during construction.

124. Due to the above, any release of sediments from pre-drilling below the sea bed is of greater potential significance. This would be associated with the installation of monopile or pin pile (for jacket) foundations that may be required for the Project. This has been considered as the worst-case scenario for this impact.

125. In practice, the pre-drilling work required for foundations will progress sequentially over time (rather than being instantaneous). Therefore, the realistic worst-case scenario is sediment release from one foundation location at a time. Under this scenario, any plume that is generated would disperse well before the potential exists for its coalescence with plumes from adjacent (or any other) pre-drill locations.

126. The total volume of sediment released from pre-drilling for monopile or pin pile installation would be extremely small (1,020 m^3 per foundation). From experience of other schemes, this is likely to result in peak increases in suspended sediment concentration at the points of release within the Project being only a few mg/l (typically less than 10 mg/l) and peak values at only a short distance from each release point reducing rapidly to less than 1 mg/l. This low (barely measurable) effect is partly due to the low volume of sediment released from drilling at the

location of each release point, and partly because any fine material released would be rapidly dispersed by the strong tidal currents along the axis of tidal flow.

127. The maximum envisaged effect associated with sediment plumes arising from the foundation installation activities will cause only very minor enhancements in suspended sediment concentration (typically less than 1 mg/l a short distance from the release point) over only a small geographical area (a few hundred metres). The effects will be temporary, with a return to very low background concentrations occurring rapidly upon cessation of installation activities (i.e. the effect is temporary only). Other than at the immediate release point, such a change would be immeasurable. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-21**.

Table 7-22 Magnitude of Effects on Suspended Sediment Concentrations During Foundation Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

128. Changes in the suspended sediment concentrations arising from foundation installation do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume (see Impact 2, **Section 7.7.5.2**). There is no physical pathway that links the source of the impact to the beaches and sea cliffs before the plume is diminished. Hence, there is **no change** to these identified shoreline geomorphological receptors. There is a direct physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, but plume effects are **negligible** near this sea bed geomorphological receptor.

129. These changes in suspended sediment concentrations arising from foundation installation are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.1.1. Mitigation

130. There is no suggested mitigation.

7.7.5.1.2. Residual Impact

131. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.5.2. Impact 2: Changes in Sea Bed Level (Morphology) Due to Deposition During Foundation Installation in the Project

132. Any sediment that becomes entrained within the plume generated by foundation installation will have the potential to deposit on the sea bed at some distance from its point of release, as it settles through the water column. Similar to Impact 1 (**Section 7.7.5.1**), the greatest potential

effect would arise from the release of sediment into the water column from pre-drilling for monopile installation.

133. Based upon a realistic worst-case of sediment release from a single monopile at a time, the sediment deposition on the sea bed will be extremely small in thickness. From experience of similar schemes, it is envisaged that in the immediate vicinity of the release point, deposition depths of no more than 0.1 m will be observed. These sediments are then highly likely to become re-entrained by currents during the peak velocities of the following tide and transported further away in small concentrations.

134. Further away from the release point, the deposition of sediments would extend over a similar zone of influence to that of the sediment plume (i.e. within a few hundred metres of each release point, following the axis of the tidal current flow), but the thickness of deposits would be extremely small, typically millimetres. In such a highly dynamic tidal area, this would be an immeasurable change.

135. As sediment plumes and sediment deposition will be governed by the axis of the tidal flows, there is limited potential for the sediment deposited from different turbine locations to coalesce and remain on the sea bed in any measurable magnitude within this area of strong tidal currents. Rather, deposited sediments would be very quickly re-suspended and redistributed across a wide area in low (immeasurable) quantities. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-22**.

Table 7-23 Magnitude of Effects On Sea Bed Levels Due to Sediment Deposition Associated with Foundation Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

136. There is no physical pathway that links the source of the impact arising from foundation installation to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors. However, there is a direct physical pathway that links the source of the impact arising from foundation installation to the offshore sand ridge in the north of the MDZ, but deposition effects are **negligible** near this sea bed geomorphological receptor.

137. Changes in sea bed level due to sediment deposition arising from foundation installation are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.2.1. Mitigation

138. There is no suggested mitigation.

7.7.5.2.2. Residual Impact

139. The residual impact on the identified shoreline geomorphological receptors (beaches and sea cliffs) remains **no change** and on the identified sea bed geomorphological receptor (offshore sand ridge) remains **negligible**.

7.7.5.3. Impact 3: Changes in Suspended Sediment Concentrations During Offshore Export Cable Installation (including Nearshore and Landfall)

140. During the construction phase only, there is potential for offshore export cable installation activities within the cable corridor (including the nearshore and landfall) to disturb sediments and release them into the water column as a plume. This will enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments settle once again on the sea bed.

141. The principal causes of sediment disturbance during offshore cable installation would be:

- Free-laying of up to 40.5 km of offshore export cable on the sea bed;
- Placement of cable protection (rock bags of concrete mattresses) at specific locations along the cable length; and
- Post-installation jetting to bury offshore cable across the sand ridge feature in the northern half of the cable corridor.

142. The offshore parts of the cable corridor are mostly governed by large areas of outcropping bedrock, with minimal relief and only sparse sediment cover, predominantly gravel, cobbles and rock boulders. However, the northern part of the cable corridor is covered by a sand ridge north of South Stack headland and extending northwest for around 1 km. This is where post-lay jetting may be required to bury the offshore cable, which would cause some sea bed sediment disturbance.

143. Nearer to the landfall, Abraham's Bosom is a bay bounded by rock headlands to the north and south, with a cover of sediment overlying bedrock. The grab sample from this location recovered medium-grained sand. Just offshore of the bay is a patch of megaripples (up to 0.6 m high).

144. The free-laying of cables and the placement of cable protection would not cause plumes along the offshore sections of the cable corridor because the sea bed is characterised by bedrock or, where sparse sediment cover does exist, by sediments with a particle size that cannot be suspended in the water column. In the nearshore, the bedrock is overlain by sand which has the potential to be disturbed by the free-laying of cables and the placement of cable protection. However, any plume arising from these activities would only arise from the force of the cable or protection measures on the sea bed.

145. At the landfall, the worst-case scenario would be open trenching rather than the preferred option of HDD. Under open trenching, up to 7,440 m^3 of sand would be excavated and the majority replaced to backfill the trench, with only a small net loss to the inshore system. Due to these factors, the likely increase in suspended sediment concentration in areas with sand cover nearer to shore (including at the landfall) will remain within the bounds of natural behaviour that are governed by storm waves and surge effects. Furthermore, these effects will be one-off and temporary in duration and are unlikely to be measurable.

146. The principal effect would arise from the post-installation jetting to bury the offshore cable across the sand ridge feature in the northern half of the cable corridor. Under this activity, it is likely that the maximum envisaged effect associated with sediment plumes arising from the jetting will cause only modest (but measurable) increases in suspended sediment concentration locally (typically a few tens of mg/l above background levels). This increase would reduce rapidly with distance from the point of disturbance to a few mg/l over a small geographical area (within a few hundred metres, along the axis of tidal currents). Furthermore, these effects will be one-off and temporary in duration, with a return to the very low background concentrations occurring rapidly upon cessation of installation. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-24**.

147. Changes in the suspended sediment concentration do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume (see Construction Impact 4). There is a direct physical pathway that potentially links the source of the impact (arising at the landfall) to the beaches and sea cliffs before the plume is diminished, but plume effects are **negligible** near these geomorphological receptors. There is also a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but plume effects are **low** near this geomorphological receptor.

Table 7-24 Magnitude of Effects on Suspended Sediment Concentrations During Offshore Cable and Cable Protection Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Low (sand ridge) to Negligible (elsewhere)
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

148. These changes in suspended sediment concentration arising from offshore cable installation are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.3.1. Mitigation

149. There is no suggested mitigation.

7.7.5.3.2. Residual Impact

150. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.5.4. Impact 4: Changes in Sea Bed Level Due to Offshore Cable Installation (including Nearshore and Landfall)

151. Any sediment that becomes entrained within the plume generated by offshore cable installation (Impact 3, **Section 7.7.5.3**) during the construction phase only will have the potential to become deposited on the sea bed at some distance from its point of release as it settles through the water column. Similar to the plume effects, the greatest potential depositional effects would be associated with the post-installation jetting to bury the offshore cable across the sand ridge feature in the northern part of the cable corridor. Other depositional effects (e.g. sediment disturbed from the free-laying of cables or the placement of cable protection on the sea bed) will remain within the bounds of natural behaviour that are governed by storm waves and surge effects, with construction phase effects being one-off and temporary in duration, and unlikely to be measurable.

152. From experience of similar schemes, it is envisaged that in the immediate vicinity of the post-lay jetting through the sand ridge, deposition depths of no more than 0.1 m will be observed. These are highly likely to become re-entrained by currents during the peak velocities of the following tide and transported further away in small concentrations.

153. Further away from the immediate vicinity of the post-lay jetting, the deposition of sediments would extend over a similar zone of influence to that of the sediment plume (i.e. within a few hundred metres of each release point, following the axis of the tidal current flow). Within a short distance from the release points the thickness of deposits will be extremely small, typically millimetres. In this highly dynamic tidal area, this is effectively an immeasurable change. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-25**.

Table 7-25 Magnitude of Effects on Sea Bed Levels Due to Sediment Deposition Associated with Offshore Cable and Cable Protection Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

154. There is a direct physical pathway that potentially links the source of the impact (arising at the landfall) to the beaches and sea cliffs, but effects on sea bed and beach levels are **negligible** for these geomorphological receptors. There is also a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but effects on sea bed levels are **negligible** for this geomorphological receptor.

155. Changes in sea bed level due to sediment deposition arising from foundation installation are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.4.1. Mitigation

156. There is no suggested mitigation.

7.7.5.4.2. Residual Impact

157. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.5.5. Impact 5: Changes in Suspended Sediment Concentrations During Inter-Array Cable Installation

158. During the construction phase there is potential for inter-array cable installation activities within the Project to disturb sediments and release them into the water column as a plume. This would enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments settle once again on the sea bed.

159. The principal causes of sediment disturbance during inter-array cable installation would be:

- Free-laying of up to 204.5 km of inter-array cable on the sea bed; and
- Placement of cable protection (rock bags of concrete mattresses) at specific locations along the cable length.

160. The substrate across the Project is mostly large areas of outcropping bedrock, with minimal relief and only sparse sediment cover, predominantly gravel, cobbles and rock boulders. Only in the south and southwest of the Project does the sea bed have any sediment that could potentially be affected by inter-array cable or cable protection installation, where megaripples are present with heights up to 0.6 m.

161. The free-laying of inter-array cables and the placement of cable protection would not cause plumes to be created in most areas of the Project because these areas are characterised by bedrock or, where sparse sediment cover does exist, by sediments which have particle sizes that cannot be suspended in the water column. In the areas with megaripples, plumes may locally and temporarily arise from these activities, but only due to the impact force of the cable or protection measures on the sea bed. Hence, the likely increases in suspended sediment concentration in areas with megaripples would remain within the bounds of natural behaviour that are governed by storm waves and surge effects. Furthermore, these construction-related effects will be one-off and temporary in duration and are unlikely to be measurable. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-26**.

Table 7-26 Magnitude of Effects on Suspended Sediment Concentrations During Inter-Array Cable and Cable Protection Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

162. Changes in the suspended sediment concentrations do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume (Impact 6, **Section 7.7.5.6**). There is no direct physical pathway that potentially links the source of the impact to the beaches and sea cliffs before the plume is diminished, and so there

is **no change** in these shoreline geomorphological receptors. There is a direct physical pathway that potentially links the source of the impact (arising in parts of the Project) to the offshore sand ridge, but plume effects are **negligible** near this geomorphological receptor.

163. These changes in suspended sediment concentration arising from inter-array cable installation are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.5.1. Mitigation

164. There is no suggested mitigation.

7.7.5.5.2. Residual Impact

165. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.5.6. Impact 6: Changes in Sea Bed Level Due to Inter-Array Cable Installation

166. Any sediment that becomes entrained within a plume generated by inter-array cable installation or placement of cable protection (Impact 5, **Section 7.7.5.5**) will have the potential to become deposited on the sea bed at some distance from its point of release as it settles through the water column. However, these depositional effects will remain within the bounds of natural behaviour, with construction phase effects being one-off and temporary in duration and unlikely to be measurable.

167. The deposition of sediments arising from plumes associated with inter-array cable installation or cable protection would likely be immeasurable. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-27**.

Table 7-27 Magnitude of Effects on Sea Bed Levels Due to Sediment Deposition Associated with Inter-Array Cable and Cable Protection Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

168. There is no physical pathway that links the source of the impact arising from inter-array cable installation to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors. However, there is a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but effects on sea bed levels are **negligible** for this geomorphological receptor.

169. Changes in sea bed level due to sediment deposition arising from inter-array installation are also important to consider in the assessment of impacts on benthic and intertidal ecology (see

Chapter 9, Benthic and Intertidal Ecology), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.6.1. Mitigation

170. There is no suggested mitigation.

7.7.5.6.2. Residual Impact

171. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.5.7. Construction Impact 7: Changes in Sea Bed Level Due to Indentations During Installation in the Project

172. During the construction phase, specialist vessels will be used for installation activities. While these are present at the site, their jack-up legs or anchors will exert influences in the form of scars or indentations on the sea bed morphology.

173. Due to the predominance of exposed bedrock on the sea bed, with occasional gravel cobbles and boulders, the legs / anchors of the vessels will not cause significant effects. In areas where a sand ridge is present (in the north of the Project) or where megaripples are present (in the south and southwest of the Project), there will be local effects on the sand surface. However, due to the high tidal energy environment across these areas, any depressions are likely to become rapidly re-worked after the legs / anchors are removed. Furthermore, at each location these effects will be highly localised, one-off and temporary in duration. Based on this qualitative assessment the likely magnitudes of effect are shown in **Table 7-28**.

Table 7-28 Magnitude of Effects on Sea Bed Levels Due to Indentations During Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	No effect	Negligible	Negligible	Negligible	Negligible

174. There are no areas where the legs / anchors of vessels are likely to affect the beaches and cliffs and therefore there is **no change** in the shoreline geomorphological receptors. Changes in sea bed level due to indentations during installation activities are **negligible** for the sea bed geomorphological receptor.

175. Changes in sea bed level due to indentations during installation are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.5.7.1. Mitigation

176. There is no suggested mitigation.

7.7.5.7.2. Residual Impact

177. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.6. Potential Impacts During Operation

7.7.6.1. Impact 1: Changes to the Tidal Regime Due to Presence of Structures in the Project

178. Once installed within the MDZ, tidal devices have the intention of affecting the baseline tidal regime due to the extraction of energy from the tidal currents. This will result in the formation of wakes within the hydrodynamic current flow arising from each tidal device within the Project. The overall effect will be to (mainly) pacify the existing tidal regime downstream of the tidal devices, when compared to the pre-existing (baseline) situation, recognising that the location of this wake will change along the axis of tidal flow depending on the stage of the tide. Wake effects have been visually observed at the water surface on previous tidal device deployments (e.g. SeaGen deployment in Strangford Lough, Northern Ireland). There could also be some (less significant) local increases in current speed between the wakes of adjacent tidal devices and/or around some of the foundations or support structures within the site.

179. The changes caused by the tidal devices and their foundations or support structures could lead to a modification of the tidal regime downstream of an individual tidal device (device scale), downstream of a sub-zone occupied by a small array of tidal devices (near-field scale) or across the whole demonstration site and beyond (far-field scale).

180. To investigate this issue, numerical modelling has been used to determine the changes in the baseline tidal regime arising from the worst-case scenario. The modelling was undertaken principally to assess the effects of tidal energy resource extraction on the levels of resource available to adjacent projects within the MDZ. The results are also of direct relevance to this chapter of the ES in terms of the effects on the baseline tidal regime within the demonstration site, across surrounding sea bed areas and at the adjacent shoreline.

181. A very high resolution 2D finite element model was set-up, calibrated and run to simulate the effects on the baseline tidal regime. The modelling considered ‘generic turbine rotor characteristics’ as follows:

- 20 rotor diameter turbines
- 4.5D spacings (along e-w alignment)
- Mid-depth in water column
- Each device rated 595kW electrical power

182. This rating of device yielded four scenarios, using the indicative subzones shown in **Figure 4-4** (**Volume II**):

- Scenario 1 – 60 MW total capacity, with a total of 102 turbines within the MDZ (17 no. turbines installed in each of subzones 2 – 6 and 8);
- Scenario 2 – 120 MW total capacity, with a total of 204 turbines within the MDZ (34 no. turbines installed in each of subzones 2 – 6 and 8);

- Scenario 3 – 180 MW total capacity, with a total of 306 turbines within the MDZ (51 no. turbines installed in each of subzones 2 – 6 and 8); and
- Scenario 4 – 240 MW total capacity, with a total of 408 turbines[3] within the MDZ (17 no. turbines installed in each of subzones 1 – 8) (**Plate 7-9**).

183. As this is a demonstration site with a wide Project Design Envelope, there will potentially be a vast number of different (presently unknown) layouts, types and ratings of device in reality selected from within the Project Description. It is not possible or proportionate to model each and every permutation, so instead the modelling approach was to assess the effects from an indicative array, to provide insight into potential scale of effects from various scales of deployment. It used a generic exemplar that was considered to be representative of extent and magnitude effects on physical processes.

184. If in reality a larger number of devices (up to 620) was used than has been modelled, then those devices will be of smaller rating and therefore of smaller physical size. Thus, they would each have a smaller individual effect than has been modelled, so the array-scale effects from the modelled scenario would likely be conservative.

185. For deployment of arrays, the MDZ may be spilt into a series of subzones, with the zones allowing the demarcation of different technology types. Eight indicative subzones within the MDZ are shown in **Plate 7-9**, however, these indicative zones may be modified to meet the requirements of tenants and regulators.

186. Since the precise configuration, type and characteristics of the tidal devices to be deployed within each sub-zone of the MDZ will not be known until a later date, generic turbine characteristics, dimensions, power curves and thrust curves were used in the assessments, together with a specific configuration of the multiple arrays of tidal stream devices within the MDZ focused on optimising deployments within locations of greatest baseline tidal current flows. This involved simulation of effects from devices with 20 m rotor diameters, placed at 4.5D spacings (east to west within each row) and located at mid-depth in the water column. Successive rows were spaced 333 m apart with turbines staggered by 2.25D in an east-west direction between rows. The model was run for a 44-day simulation period covering a complete lunar cycle. Further details of the numerical modelling set-up, calibration and runs are provided in **Appendix 7.1** (**Volume III**).

187. Results from the modelling of all four scenarios show that the greatest changes in baseline tidal currents occur at the peak of the flood flow or the peak of the ebb flow, with changes being greater on a mean spring tide than on a mean neap tide.

---

[3] *Even though worst-case no. of TECs stated in earlier sections was 620, the max. total of 408 TEC's used in Scenario 4 were worst-case for this specific assessment. The modelling used an indicative array, to provide insight into potential scale of effects from various scales of deployment. It used a generic exemplar that was considered to be potentially most impactful representative of effects on physical processes. Development of the project description continued after the modelling.*

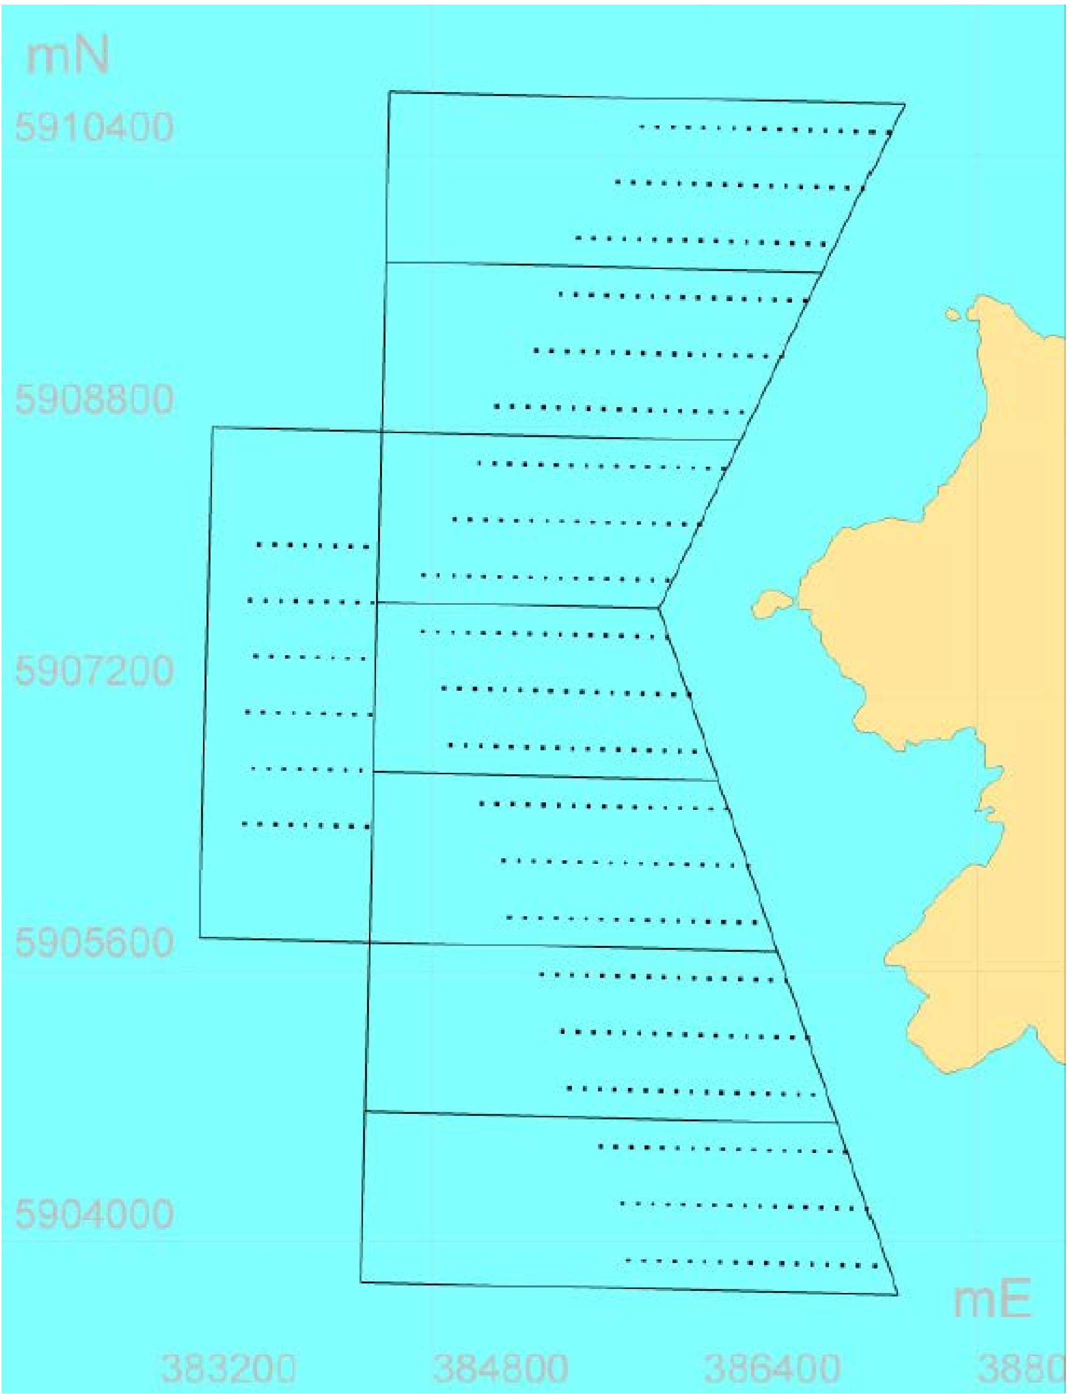

Plate 7-9 Arrays of Tidal Devices Across All Eight Subzones of the MDZ for the 240MW Worst Case Model Run

7.7.6.1.1. Scenario 1 (60 MW Capacity, 102 Turbines) - Peak Flood Flow on a Mean Spring Tide

188. **Figure 7-8 (Volume II**) shows that reductions of up to 0.3 – 0.4 m/s in baseline current speeds are predicted locally across small areas in the easternmost parts of subzones 1, 2 and 3 within the MDZ under peak flood flow on a mean spring tide. However, typically the reductions are in the range 0.1 – 0.3 m/s within around two-thirds of subzones 1 and 2 (entire central and eastern parts) and a smaller area within sub-zone 3 (typically in part of the eastern side). The changes in baseline tidal regime extend beyond the northern limits of the MDZ, following the axis of the baseline tidal currents as they flow northeast around Holy Island.

189. The remainder of subzones 1 and 2 (i.e. western parts) show no change in baseline conditions. Elsewhere, the wakes (with reductions in flow typically of 0.1 – 0.2 m/s) are locally focused around individual turbines within subzones 3 (western and central parts), 4, 5, 6 and 8, with no change in sub-zone 7 (which has no turbines present under this scenario).

7.7.6.1.2. Scenario 1 (60 MW Capacity, 102 Turbines) - Peak Ebb Flow on a Mean Spring Tide

190. **Figure 7-9** (**Volume II**) shows predicted reductions of up to 0.2 – 0.3 m/s in baseline current speeds across the central parts of subzones 6 and 7 under peak ebb flow on a mean spring tide. However, typically the reductions are in the range 0.1 – 0.2 m/s across large portions of subzones 4, 5, 6, 7 and 8, with changes in baseline tidal regime of this magnitude also extending beyond the southern limit of the MDZ, following the axis of the baseline tidal currents as they flow towards the south-southeast.

191. More confined wakes (with reductions in flow of 0.1 – 0.2 m/s) are predicted in subzones 2 and 3 with no change in sub-zone 1 (which has no turbines present under this scenario).

7.7.6.1.3. Scenario 2 (120 MW Capacity, 204 Turbines) - Peak Flood Flow on a Mean Spring Tide

192. **Figure 7-10 (Volume II**) shows that reductions of up to 0.6 – 0.7 m/s in baseline current speeds are predicted locally within subzones 1 and 2. However, more typically the peak changes in the eastern half of these subzones, and extending a small distance into sub-zone 3, are in the range 0.4 – 0.6 m/s. Reductions of up to 0.5 m/s also extend beyond the northern limits of the MDZ, following the axis of the baseline tidal currents towards the northeast.

193. Over the central parts of subzones 1 and 2 and the eastern part of sub-zone 3, the reductions are typically in the range 0.1 – 0.4 m/s with this zone of effect also extending beyond the northern limits of the MDZ, towards the northeast around Holy Island and approaching closer to shore off the north coast of Holy Island.

194. The central parts of subzones 3, 4 and 5 and the central northern segment of sub-zone 8 have reductions in flow of 0.1 – 0.2 m/s. In sub-zone 6, the wakes are confined to individual devices (with local reductions up to 0.1 – 0.2 m/s) whilst there is no change in sub-zone 7 (which has no turbines present under this scenario).

7.7.6.1.4. Scenario 2 (120 MW Capacity, 204 Turbines) - Peak Ebb Flow on a Mean Spring Tide

195. **Figure 7-11 (Volume II**) shows that reductions of up to 0.5 – 0.6 m/s in baseline current speeds are predicted locally across the central part of sub-zone 6. However, typically the peak reductions across the central parts of subzones 5, 6 and 7, extending slightly south of the southern limit of the MDZ, are in the range 0.4 – 0.5 m/s. Changes in tidal currents of around 0.1 – 0.3 m/s are also experienced offshore from Abraham’s Bosom.

196. Large parts of subzones 2, 3 and 8, as well as most of subzones 4, 5, 6 and 7 show reductions in baseline flow of 0.1 – 0.4 m/s. A zone of effect of this magnitude also extends south of the southern boundary of the MDZ by up to 5 km.

197. Sub-zone 1 (which has no turbines present under this scenario) is predicted to show no change in baseline conditions.

7.7.6.1.5. Scenario 3 (180 MW Capacity, 306 Turbines) - Peak Flood Flow on a Mean Spring Tide

198. **Figure 7-12** (**Volume II**) shows that reductions in baseline tidal currents of up to 0.8 m/s are predicted to occur across the eastern side of sub-zone 1 (and a small part of sub-zone 2), with reductions up to 0.6 m/s common throughout the central and eastern parts of subzones 1 and 2 and the eastern part of sub-zone 3. Effects of this magnitude also extend around 1 km to the northeast of the northern boundary of the MDZ, before diminishing to reductions of around between 0.1 – 0.4 m/s for a further 3.5 km to the northeast along the axis of baseline flood flows. Changes in tidal currents of around 0.1 – 0.3 m/s are also experienced closer to shore off the north coast of Holy Island.

199. Elsewhere within the MDZ, the reductions are typically in the range 0.1 – 0.4 m/s throughout significant areas of indicative subzones 3, 4, 5, 6 and the northern parts of 8.

200. Sub-zone 7 (which has no turbines present under this scenario) is predicted to show no change in baseline conditions.

7.7.6.1.6. Scenario 3 (180 MW Capacity, 306 Turbines) - Peak Ebb Flow on a Mean Spring Tide

201. **Figure 7-13** (**Volume II**) shows that peak reductions in baseline tidal currents of up to 0.8 m/s occur only locally, within sub-zone 6, but reductions between 0.4 – 0.7 m/s are predicted more commonly throughout the central and eastern parts of subzones 4 (part), 5, 6 and 7. Effects of this magnitude also extend around 750 m to the southeast of the southern boundary of the MDZ, before diminishing to reductions of around between 0.1 – 0.4 m/s for a further approximately 3.5 km to the southeast along the axis of baseline flood flows. Changes in tidal currents of around 0.1 – 0.4 m/s are also predicted offshore from Abraham’s Bosom.

202. Elsewhere within the MDZ, the reductions in current velocity are typically in the range 0.1 – 0.4 m/s throughout significant areas of subzones 2 and 3, and the western parts of subzones 4, 5, 6 and 7, as well as the southern and central parts of sub-zone 8.

203. Sub-zone 1 (which has no turbines present under this scenario) shows no change in baseline conditions.

7.7.6.1.7. Scenario 4 (240 MW Capacity, 408 Turbines) - Peak Flood Flow on a Mean Spring Tide

204. **Figure 7-14** (**Volume II**) shows that reductions in baseline tidal currents of up to 0.8 m/s are predicted to occur across the entire eastern side of sub-zone 1 (and a small part of the sub-zone 2), extending around 1 km to the northeast of the northern boundary of the MDZ.

205. Elsewhere, predicted peak reductions in current velocity are 0.6 – 0.7 m/s across much of sub-zone 2, reducing to 0.5 – 0.6 m/s across much of sub-zone 3 and part of sub-zone 4, and reducing further to 0.4 – 0.5 m/s across central parts of sub-zone 5. The zone of effect of this magnitude beyond the northern limit if the MDZ extends for a distance of about 3 km northeast of the northern boundary. Changes in tidal currents of around 0.1 – 0.4 m/s are also predicted approaching closer to shore off the north coast of Holy Island.

206. The wake effects are also observed across central and eastern parts of subzones 6 and 7, the northern central part of sub-zone 8, and extending 2.5 km to the northeast of the MDZ, but at a lower magnitude of change, typically 0.1 – 0.4 m/s.

7.7.6.1.8. Scenario 4 (240 MW Capacity, 408 Turbines) - Peak Ebb Flow on a Mean Spring Tide

207. **Figure 7-15** (**Volume II**) shows that predicted peak reductions in baseline tidal currents of up to 0.8 m/s occur only locally, within subzones 6 and 7, but reductions between 0.4 – 0.7 m/s are predicted more commonly throughout the central and eastern parts of subzones 4, 5, 6 and 7. Effects of this predicted magnitude also extend around 1 km to the southeast of the southern boundary of the MDZ, before diminishing to reductions of around 0.1 – 0.2 m/s for a further 4 km to the south-southeast along the axis of baseline flood flows. Changes in tidal currents of around 0.1 – 0.3 m/s are also predicted offshore from Abraham's Bosom.

208. Elsewhere within the MDZ, the predicted reductions are typically 0.1 – 0.4 m/s throughout significant areas of subzones 2 and 3, and westernmost parts of subzones 4, 5, 6 and 7, as well as the southern and central parts of sub-zone 8.

209. Sub-zone 1 (which does have turbines present under this scenario) shows predicted reductions of up to 0.1 – 0.3 m/s, over only a small area.

7.7.6.1.9. Summary

210. Overall, the modelling results show that there is a predicted increase in the effect on baseline tidal conditions with increasing capacity of the arrays within the subzones of the MDZ. The effects occur: (i) local to individual devices; (ii) from one array to another array within the MDZ; and (iii) from the MDZ to surrounding areas of sea bed.

211. The zone of influence of effect tends to follow the axes of baseline tidal flows, extending northeast beyond the MDZ on a flood tide and south-southeast beyond the MDZ on an ebb tide.

212. However, in even the worst-cases, the magnitude of reduction in tidal current flow (up to 0.8 m/s) results in a residual current flow of high speeds, because the baseline flow conditions in these most affected areas are typically greater than 2 m/s.

213. Based on the qualitative and quantitative modelling assessments the likely magnitudes of effect are shown in **Table 7-29**.

Table 7-29 Magnitude of Effects on Tidal Regime Due to the Presence of Structures in the Project

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Device	Medium	High	Medium	Negligible	Medium
Near-field	Low - Medium	High	Medium	Negligible	Low - Medium
Far-field	Negligible	High	Medium	Negligible	Negligible

214. Changes in the tidal regime do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of effects arising from any changes to sediment erosion or deposition associated with the changes in tidal regime (see Operational Impact 3).

215. As there is no physical pathway that links the source of the impact to the beaches and sea cliffs before the wake effect on the tidal velocities is back to baseline, there is **no change** to these identified shoreline geomorphological receptors. There is a direct physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, and the magnitude of changes in the tidal regime are **low - medium** near this sea bed geomorphological receptor.

7.7.6.1.10. Mitigation

216. There is no recommended further mitigation.

7.7.6.1.11. Residual Impact

217. The magnitude of change in tidal regime at the shoreline receptor remains **no change** and at the sea bed receptor remains at **low – medium** change.

7.7.6.2. Impact 2: Changes to the Wave Regime Due to Presence of Structures in the Project

218. Once installed within the MDZ, tidal devices and their associated foundations or support structures will have the potential to affect the baseline wave regime. This would be most notable for devices with foundations/support structures that occupy the greatest height within the water column and present the greatest cross-sectional area as a solid mass, causing the greatest potential for blockage.

219. The changes caused by the tidal devices and their foundations or support structures could lead to a modification of the wave regime downstream of an individual tidal device and its foundation or support structure (device scale), downstream of a sub-zone occupied by a small array of tidal devices (near-field scale) or across the whole demonstration site and beyond (far-field scale). To further investigate this issue, experience from the offshore wind farm industry is drawn upon.

220. For monopiles, wave theory exists which relates the pile diameter (D) to the wavelength (L) of the incident waves. Diffraction effects become important when $D/L \geq 0.2$. Using wavelengths typical of the demonstration site, which is often characterised by long period Atlantic swell, wave diffraction is not envisaged to be induced at the MDZ by a monopile foundation. This confirms that effects on the wave regime from a monopile would be confined to local scale reflections and blockage, and that the wave trains will regroup and return to baseline values within a short distance from each foundation.

221. For GBS, which are likely to represent the worst-case foundation type due to their occupation of a greater cross sectional area within the water column, there is a strong evidence base which demonstrates that the changes in the wave regime due to the presence of foundation structures (even under a worst-case scenario of the largest diameter GBS considered by the offshore wind farm industry to date), are relatively small in magnitude (typically less than 10 % of baseline wave heights in close proximity to each wind turbine, reducing with greater distance from each turbine). Effects are localised in spatial extent, extending as a shadow zone typically up to several tens of kilometres from the site along the axis of wave approach, but with low magnitudes (only a few percent change across this wider area). This is confirmed by a review of modelling studies from over 30 offshore wind farms in the UK and European waters (Seagreen 2012), existing guidance documents (ETSU 2000; ETSU 2002; Lambkin *et al*. 2009), published research (Ohl *et al*. 2001) and post-installation monitoring (Cefas 2005).

222. Based on the above assessment the likely magnitudes of effect are shown in **Table 7-30**.

Table 7-30 Magnitude of Effects on Wave Regime Due to the Presence of Structures in the Project

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Device	Medium	High	Medium	Negligible	Medium
Near-field	Low	High	Medium	Negligible	Low
Far-field	Negligible	High	Medium	Negligible	Negligible

223. Changes in the wave regime do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of effects arising from any changes to sediment erosion or deposition associated with the changes in wave regime (see Impact 3, **Section 7.7.6.3**).

224. As there is no physical pathway that links the source of the impact to the beaches and sea cliffs before the shadow effect on the wave regime is diminished, there is **no change** to these identified shoreline geomorphological receptors. There is a direct physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, and the magnitude of changes in the wave regime are **low** near this sea bed geomorphological receptor.

7.7.6.2.1. Mitigation

225. There is no recommended further mitigation.

7.7.6.2.2. Residual Impact

226. The magnitude of change in wave regime at the shoreline receptor remains **no change** and at the sea bed receptor remains at **low – medium** change.

7.7.6.3. Impact 3: Changes to the Sediment Transport Regime Due to Presence of Structures in the Project

227. Changes in the sediment transport regime will arise as either: (i) an indirect effect, consequent upon changes in the tidal and/or wave regimes caused by tidal devices and their foundations; or (ii) a direct effect due to blockage of (bedload) sediment transport by the foundations of tidal devices or electrical hubs on the sea bed within the Project.

228. As the magnitude of impacts on the tidal regime (Impact 1, **Section 7.7.6.1**) and wave regime (Impact 2, **Section 7.7.6.2**) are negligible across the far-field, then the associated knock-on effects on sediment transport will also be negligible across the far-field.

229. At a device scale, the worst-case for potential blockage of (bedload) sediment transport by foundations is associated with the use of GBS for all devices deployed in a 240 MW array. Under the worst case seabed footprint deployment scenario detailed in **Chapter 4, Project Description**, there could, potentially, be up to 590 devices plus 120 hubs, all deploying GBS, with a seabed footprint of up to 74,790 m^2 within the MDZ.

230. However, at the demonstration site there is little mobile sediment available for bedload transport. This is because the sea bed has been swept to bedrock (with or without a gravel, cobble, boulder

lag) by strong tidal currents. Given this dominant process, the potential for interruption or disturbance of sediment transport by the foundations and electrical hubs is limited. The greatest potential effect will arise in the immediate vicinity of the sand ridge in the north of the MDZ and the area of megaripples in the south and southwest of the MDZ. However, it is unlikely that any project infrastructure will present such an obstacle to sediment transport locally that far-reaching effects will become manifest.

231. Based on the above assessment the likely magnitude of effects are shown in **Table 7-31**.

Table 7-31 Magnitude of Effects on Sediment Transport Regime Due to Presence of Structures in the Project

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Device	Low	High	Medium	Negligible	Low
Near-field	Negligible	High	Medium	Negligible	Negligible
Far-field	Negligible	High	Medium	Negligible	Negligible

232. There is no physical pathway that links the source of the impact (indirectly caused by changes to the tidal and/or wave regimes) to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors. However, there is a physical pathway that links the source of the impact arising from local (device location) changes to the tidal and/or wave regimes and direct placement of foundations in the vicinity of the offshore sand ridge in the north of the MDZ. Reductions in tidal velocities of the order expected are relatively small in relation to the very high baseline tidal flows (within a defined zone of influence) and would not result in changes to the existing erosion or deposition patterns of sediment since the critical thresholds for deposition of sediments of different grain particle sizes will still not be crossed. Consequently, these effects on the sediment transport regime are **low** at the location of the device, and **negligible** further afield.

7.7.6.3.1. Mitigation

233. There is no recommended further mitigation.

7.7.6.3.2. Residual Impact

234. The magnitude of effect on the sediment transport regime at the shoreline receptor remains **no change** and at the sea bed receptor remains at **low** (at the location of a foundation) and **negligible** elsewhere.

7.7.6.4. Impact 4: Increases in Suspended Sediment Concentrations Due to Sea Bed Scour Induced by the Project

235. The greatest potential sea bed scour effect will be associated with changes in the flow regimes around the foundations of devices as the flow bifurcates around the obstruction provided by each foundation. Where the sea bed is comprised of bare bedrock or where this is covered with boulders, cobbles or gravels there is unlikely to be any change in suspended sediment concentrations. If devices are placed in areas of the MDZ characterised by sands (e.g. southwest section and in the vicinity of the sand ridge in the north) there is potential for locally accelerated flows around foundations to increase suspended sediment concentrations, but since flows in these areas are very high in the baseline conditions, this will not be a major

exacerbation of the issue. Given the nature of the sea bed morphology, comprised mostly of exposed bedrock, the potential for adverse effects of this nature is extremely limited.

236. Based on the above assessment the likely magnitude of effects is shown in **Table 7-32**.

Table 7-32 Magnitude of Effects on Suspended Sediment Concentrations Due to Sea Bed Scour Induced by the Project

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field (direct footprint)	Low	High	Medium	Negligible	Low
Far-field	No change	No change	No change	No change	No change

237. There is no physical pathway that links the source of the impact to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors.

238. However, there is a physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, but effects are **low** at the location of each device placed across this feature.

7.7.6.4.1. Mitigation

239. There is no recommended further mitigation.

7.7.6.4.2. Residual Impact

240. The magnitude of effect on suspended sediment concentrations at the shoreline receptor remains **no change** and at the sea bed receptor remains **low** (at the location of a foundation placed on the sand ridge or sand covered bedrock), with **no change** elsewhere (areas dominated by coarser material).

7.7.6.5. Impact 5: Loss of Sea Bed Morphology Due to Footprint of Structures in the Project

241. The physical presence of foundations, support structures, mooring anchors and chains, surface-laid cables and cable protection works on the sea bed will affect the existing morphology.

242. In the case of the static infrastructure, there will be a footprint imposed on the sea bed that will directly cover the morphology. In the case of the moorings, an area of the sea bed morphology will be 'swept' by the drag of the catenary chain.

243. Given the nature of the sea bed morphology, comprised mostly of exposed bedrock, the potential for adverse effects is limited.

244. Based on the above assessment the likely magnitude of effects are shown in **Table 7-33**.

Table 7-33 Magnitude of Effects on Sea Bed Morphology Due to Footprint of Structures in the Project

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field (direct footprint)	Low	High	Medium	Negligible	Low
Far-field	No change	No change	No change	No change	No change

245. There is no physical pathway that links the source of the impact to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors.

246. However, there is a physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, but effects are **low** at the location of each device placed across this feature, and **there is no change** beyond the direct footprint.

7.7.6.5.1. Mitigation

247. There is no recommended further mitigation.

7.7.6.5.2. Residual Impact

248. The magnitude of effect on the sediment transport regime at the shoreline receptor remains **no change** and at the sea bed receptor remains **low** (at the location of a foundation placed on the sand ridge), with **no change** elsewhere.

7.7.6.6. Impact 6: Changes to the Morphology and Sediment Transport Regime Due to Offshore Cable and Cable Protection (including Nearshore and Landfall)

249. Changes in the morphology and sediment regime will potentially arise as a direct result of blockage of (bedload) sediment transport by the surface-laid offshore cables and cable protection works on the sea bed.

250. Surface-laid offshore cables, together with any cable protection works, will present an obstacle to bedload sediment transport up to a short height off the sea bed. If bedload transport processes are active, then it would be expected that a ‘ramp’ of sediment would rapidly form against the obstruction and transport process would then occur across the ramp. Such processes are observed across pipelines on the sea bed in areas of active sediment transport. If sediment transport processes are not active, then the presence of the offshore cable and cable protection present no concern in respect of this impact.

251. Across much of the offshore cable corridor, there is little mobile sediment available for bedload transport. This is because the sea bed has generally been swept to bedrock by strong tidal currents. There are exceptions to this in the northern part of the cable corridor, where a sand ridge is present, and closer to shore in Abraham’s Bosom, where sand overlies bedrock. However, the Project infrastructure at the shoreline or within the shallow nearshore that is inshore of the ‘closure depth’ of the active beach profile, will not present an obstruction to bedload sediment transport because the cable will be buried here (by HDD or trenching).

252. Based on the above qualitative assessment the likely magnitude of effects are shown in **Table 7-34**.

Table 7-34 Magnitude of Effects on Morphology and Sediment Transport Regime Due to Offshore Cable and Cable Protection

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	High	Medium	Negligible	Negligible
Far-field	Negligible	High	Medium	Negligible	Negligible

253. There is no physical pathway that links the source of the impact (either indirectly caused by changes to the tidal and/or wave regimes, or directly due to cables or cable protection) to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors.

254. However, there is a physical pathway that links the source of the impact arising from near-field changes to the tidal and/or wave regimes and direct placement of offshore cables and cable protection near the offshore sand ridge in the north of the MDZ, but effects are **negligible**.

7.7.6.6.1. Mitigation

255. There is no recommended further mitigation.

7.7.6.6.2. Residual Impact

256. The magnitude of effect on the sediment transport regime at the shoreline receptor remains **no change** and at the sea bed receptor remains **negligible**.

7.7.6.7. Impact 7: Changes to the Morphology and Sediment Transport Regime Due to Inter-Array Cable and Cable Protection

257. Changes in the morphology and sediment regime will potentially arise as a direct result of blockage of (bedload) sediment transport by the surface-laid inter-array cables and cable protection works on the sea bed.

258. Surface-laid inter-array cables, together with any cable protection works, will present an obstacle to bedload sediment transport up to a short height off the sea bed. If bedload transport processes are active, then it would be expected that a ‘ramp’ of sediment would rapidly form against the obstruction and transport process would then occur across the ramp. Such processes are observed across pipelines on the sea bed in areas of active sediment transport. If sediment transport processes are not active, then the presence of the offshore cable and cable protection presents no concern in respect of this impact.

259. Across much of the MDZ (where the inter-array cables will be installed), there is little mobile sediment available for bedload transport. This is because the sea bed has generally been swept to bedrock by the strong tidal currents. There are exceptions to this in the northern part of the MDZ where a large sand ridge is present, and in the south and southwest of the MDZ where megaripples occur. It is unlikely that any Project infrastructure will present a significant obstruction to bedload sediment transport in these areas since it will occupy only a short height above the sea bed.

260. Based on the above qualitative assessment the likely magnitude of effects are shown in **Table 7-35**.

Table 7-35 Magnitude of Effects on Morphology and Sediment Transport Regime Due to Inter-Array Cable and Cable Protection

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	High	Medium	Negligible	Negligible
Far-field	Negligible	High	Medium	Negligible	Negligible

261. There is no physical pathway that links the source of the impact (either indirectly caused by changes to the tidal and/or wave regimes, or directly due to cables or cable protection) to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors.

262. However, there is a physical pathway that links the source of the impact arising from near-field changes to the tidal and/or wave regimes and direct placement of inter-array cables and cable protection near the offshore sand ridge in the north of the MDZ, but effects are **negligible**.

7.7.6.7.1. Mitigation

263. There is no recommended further mitigation.

7.7.6.7.2. Residual Impact

264. The magnitude of effect on the sediment transport regime at the shoreline receptor remains **no change** and at the sea bed receptor remains **negligible**.

7.7.6.8. Impact 8: Changes in Sea Bed Level Due to Indentations During Maintenance in the Project

265. During the operational phase, specialist vessels will be used for maintenance activities. While these are present at the site, their jack-up legs or anchors will form scars or indentations on the sea bed.

266. Due to the predominance of exposed bedrock, with occasional gravel, cobbles and boulders, the legs / anchors of the vessels will not cause significant effects. In areas where either a sand ridge is present (in the north of the Project) or where megaripples are present (in the south and southwest of the Project), there will be local effects on the sand surface. However, due to the high tidal energy environment across these areas, any depressions are likely to be re-worked soon after the legs / anchors are removed. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-36**.

Table 7-36 Magnitude of Effects on Sea Bed Levels Due to Indentations During Installation

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	No effect	Negligible	Negligible	Negligible	Negligible

267. There are no areas where the legs / anchors of vessels are likely to affect the beaches and cliffs and therefore there is **no change** in the shoreline geomorphological receptors. Changes in sea bed level due to indentations during maintenance activities are **negligible** for the sea bed geomorphological receptor.

268. Changes in sea bed level due to indentations during maintenance are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.6.8.1. Mitigation

269. There is no suggested mitigation.

7.7.6.8.2. Residual Impact

270. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7. Potential Impacts During Decommissioning and Repowering

7.7.7.1. Impact 1: Changes in Suspended Sediment Concentrations During Device and Hub Removal in the Project

271. During the decommissioning phase the potential for device and hub removal activities within the Project to disturb sediments on the sea bed and release them into the water column as a plume is lower than the effects arising from installation of foundations.

272. This is primarily because the removal activities will cause less direct interference (i.e. no pre-drilling) and the Project substrate is largely characterised by bedrock with little surface sediment other than occasional gravel, cobbles and boulders, which would not form a plume. The only areas with sand are in the north where a sand ridge is identified and in the south and southwest where megaripples are identified in parts of the Project. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-37**.

Table 7-37 Magnitude of Effects on Suspended Sediment Concentrations Due to Device and Hub Removal

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

273. Changes in suspended sediment concentration arising from device and hub removal do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume (Impact 2, **Section 7.7.7.2**). There is no physical pathway that links the source of the impact to the beaches and sea cliffs before the plume has diminished. Hence, there is **no change** to these identified shoreline geomorphological receptors. There is a direct physical pathway that links the source of the impact to the offshore sand ridge in the north of the MDZ, but plume effects are **negligible** near this sea bed geomorphological receptor.

274. These changes in suspended sediment concentration arising from device and hub removal are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.1.1. Mitigation

275. There is no suggested mitigation.

7.7.7.1.2. Residual Impact

276. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7.2. Impact 2: Changes in Sea Bed Level (Morphology) due to Device and Hub Removal

277. Any sediment that becomes entrained within the plume generated by device and hub removal will have the potential to be deposited on the sea bed at some distance from its point of release as it settles through the water column. However, such plumes arising from decommissioning activities will be of negligible significance and the tidal currents are strong, encouraging rapid dispersion. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-38**.

278. There is no physical pathway that links the source of the impact arising from device and hub removal to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors. However, there is a direct physical pathway that links the source of the impact arising from device and hub removal to the offshore sand ridge in the north of the MDZ, but deposition effects are **negligible** in the vicinity of this sea bed geomorphological receptor.

Table 7-38 Magnitude of Effects on Sea Bed Levels Due to Sediment Deposition Arising from Device and Hub Removal

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

279. Changes in sea bed level due to sediment deposition arising from device and hub removal are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.2.1. Mitigation

280. There is no suggested mitigation.

7.7.7.2.2. Residual Impact

281. The residual impact on the identified shoreline geomorphological receptors (beaches and sea cliffs) remains **no change** and on the identified sea bed geomorphological receptor (offshore sand ridge) remains **negligible**.

7.7.7.3. Impact 3: Changes in Suspended Sediment Concentrations Due to Removal of Offshore Cable (including Nearshore and Landfall)

282. During the decommissioning phase there is potential for offshore cable removal activities within the cable corridor (including the nearshore and landfall), during the decommissioning phase only, to disturb sediments and release them into the water column as a plume. This will enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments settle to the sea bed.

283. The offshore sea bed along the cable corridor are mostly governed by large areas of outcropping bedrock, with minimal relief and only sparse sediment cover, predominantly gravel, cobbles and rock boulders. Here, cable removal will create minimal sediment plumes.

284. In the northern part of the cable corridor where the cable has been buried within a sand ridge and nearer to the landfall where there is sand over bedrock, including the presence of some megaripples, removal of the offshore cable will cause effects like those experienced during installation.

285. These effects will be one-off and temporary in duration, with a return to the very low background concentrations occurring rapidly upon cessation of removal. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-39**.

Table 7-39 Magnitude of Effects on Suspended Sediment Concentrations Due to Removal of the Offshore Cable (including Nearshore and Landfall)

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Low (sand ridge) to Negligible (elsewhere)
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

286. Changes in the suspended sediment concentration do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume (Impact 4, **Section 7.7.7.4**). There is a direct physical pathway that potentially links the source of the impact (arising at the landfall) to the beaches and sea cliffs before the plume is diminished, but plume effects are **negligible** near these geomorphological receptors. There is also a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but plume effects are **low** near this geomorphological receptor.

287. These changes in suspended sediment concentration arising from offshore cable removal are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.3.1. Mitigation

288. There is no suggested mitigation.

7.7.7.3.2. Residual Impact

289. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7.4. Impact 4: Changes in Sea Bed Level Due to Removal of Offshore Cable (including Nearshore and Landfall)

290. Any sediment that becomes entrained within the plume generated by offshore cable removal (Impact 3, **Section 7.7.7.3**), during the decommissioning phase only, has the potential to be deposited on the sea bed at some distance from its point of release as it settles through the water column. Depositional effects will remain within the bounds of natural behaviour that are governed by storm waves and surge effects, with decommissioning phase effects being one-off and temporary in duration, and unlikely to be measurable. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-40**.

291. There is a direct physical pathway that potentially links the source of the impact (arising at the landfall) to the beaches and sea cliffs, but effects on sea bed and beach levels are **negligible** for these geomorphological receptors. There is also a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but effects on sea bed levels are **negligible** for this geomorphological receptor.

Table 7-40 Magnitude of Effects on Sea Bed Levels Due to Sediment Deposition Arising from Removal of the Offshore Cable

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

292. Changes in sea bed level due to sediment deposition arising from offshore cable removal are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.4.1. Mitigation

293. There is no suggested mitigation.

7.7.7.4.2. Residual Impact

294. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7.5. Impact 5: Changes in Suspended Sediment Concentrations Due to Removal of Inter-Array Cable

295. During the decommissioning phase there is potential for inter-array cable removal activities within the Project to disturb sediments and release them into the water column as a plume. This will enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments eventually settle on the sea bed.

296. The sea bed of the Project is mostly composed of large areas of outcropping bedrock, with minimal relief and only sparse sediment cover, predominantly gravel, cobbles and rock boulders. Only in the south and southwest does the sea bed have superficial sediment that could potentially be affected by inter-array cable removal, where megaripples are present with heights up to 0.6 m.

297. Removal of the offshore cable will cause effects like those experienced during installation. These effects will be one-off and temporary in duration, with a return to the very low background suspended sediment concentrations occurring rapidly upon cessation of removal. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-41**.

298. Changes in the suspended sediment concentrations do not directly impact on the identified geomorphological receptors *per se* but are important to consider because they inform subsequent assessment of impacts arising from any sediment deposition associated with the plume arising from inter-array cable removal (Impact 6, **Section 7.7.7.6**). There is no direct physical pathway that potentially links the source of the impact to the beaches and sea cliffs before the plume has diminished, and so there is **no change** to these shoreline geomorphological receptors. There is a direct physical pathway that potentially links the source of the impact (arising in parts of the Project) to the offshore sand ridge, but plume effects are **negligible** near this geomorphological receptor.

Table 7-41 Magnitude of Effects on Suspended Sediment Concentrations During Removal of the Inter-Array Cables

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

299. These changes in suspended sediment concentrations arising from inter-array cable removal are also important to consider in the assessment of impacts on marine water quality (see **Chapter 8, Marine Water and Sediment Quality**), benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.5.1. Mitigation

300. There is no suggested mitigation.

7.7.7.5.2. Residual Impact

301. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7.6. Impact 6: Changes in Sea Bed Level Due to Removal of Inter-Array Cable

302. Any sediment that becomes entrained within the plume generated by inter-array cable removal (Impact 5, **Section 7.7.7.5**) will have the potential to be deposited on the sea bed at some distance from its point of release as it settles through the water column. However, these depositional effects will remain within the bounds of natural behaviour, with decommissioning phase effects being one-off and temporary in duration and unlikely to be measurable.

303. The deposition of sediments arising from plumes associated with inter-array cable removal will likely be immeasurable. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-42**.

Table 7-42 Magnitude of Effects on Sea Bed Levels Due to Sediment Deposition Associated with Removal of the Inter-Array Cables

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

304. There is no physical pathway that links the source of the impact arising from inter-array cable removal to the beaches and sea cliffs and therefore there is **no change** to these identified shoreline geomorphological receptors. However, there is a direct physical pathway that potentially links the source of the impact (arising in the offshore part of the cable corridor) to the offshore sand ridge, but deposition effects on sea bed levels are **negligible** for this geomorphological receptor.

305. Changes in sea bed levels due to sediment deposition arising from inter-array cable removal are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.6.1. Mitigation

306. There is no suggested mitigation.

7.7.7.6.2. Residual Impact

307. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.7.7. Impact 7: Changes in Sea Bed Level Due to Indentations in the Seabed

308. During the decommissioning phase, specialist vessels will be used for removal activities. While these are present at the site, their jack-up legs or anchors will form scars or indentations on the sea bed morphology.

309. Due to the predominance of exposed bedrock on the sea bed, with occasional gravel, cobbles and boulders, the legs / anchors of the vessels will not cause significant effects. In areas where either a sand ridge is present (in the north of the Project) or where megaripples are present (in the south and southwest of the Project), there will be localised effects on the sand surface, but due to the high tidal energy environment across these areas, any depressions are likely to become re-worked soon after the legs / anchors are removed. Furthermore, at each location these effects will be local, one-off and temporary in duration. Based on this qualitative assessment the likely magnitude of effects are shown in **Table 7-43**.

Table 7-43 Magnitude of Effects on Sea Bed Levels due to Indentations in the Seabed

Location	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
Far-field	No effect	Negligible	Negligible	Negligible	Negligible

310. There are no areas where the legs / anchors of vessels are likely to affect the beaches and cliffs and therefore there is **no change** in the shoreline geomorphological receptors. Changes in sea bed level due to indentations during decommissioning activities are **negligible** for the sea bed geomorphological receptor.

311. Changes in sea bed level due to indentations during installation are also important to consider in the assessment of impacts on benthic and intertidal ecology (see **Chapter 9, Benthic and Intertidal Ecology**), and fish and shellfish (see **Chapter 10, Fish and Shellfish Ecology**).

7.7.7.7.1. Mitigation

312. There is no suggested mitigation.

7.7.7.7.2. Residual Impact

313. The residual impact on the identified shoreline geomorphological receptors remains **no change** and on the identified sea bed geomorphological receptor remains **negligible**.

7.7.8. Cumulative and In-Combination Impacts

314. Of the projects listed in **Chapter 26, Cumulative and In-combination Effects**, the only one which could potentially have a cumulative or in-combination effect with the MDZ Project in respect of coastal processes is Minesto's Holyhead Deep. All other projects are either too remote from the Project or on land and thus do not affect coastal processes.

Minesto's Holyhead Deep project will be a 80 MW installation of tidal energy devices, delivered in a phased manner, and located a short distance due west of the MDZ Project. Based upon the geographical configuration of the Minesto Project Development Area (PDA) with respect to the MDZ Project, there is no possibility of changes in tidal flow interacting between projects, due to the alignment of flood and ebb flows off the coast of Anglesey (i.e. the two projects are not upstream/downstream of each other).

315. Similarly, any (minor) sediment plumes arising from construction from either project will not coalesce because of: (i) the alignment of principal tidal flows; and (ii) likely different construction programmes (note that phase 1 of the Holyhead Deep project is already installed).

316. The predicted impacts of Minesto's Holyhead Deep project on coastal processes have been assessed as being not significant in their own right (Minesto, 2016), and this conclusion is considered equally valid when both projects are considered in combination.

7.7.9. Inter-relationships

317. The range of effects on marine physical processes of the Project have the potential to directly affect the identified marine physical processes receptors but may also manifest as impacts upon receptors other than those considered within the context of marine physical processes. The assessments of significance of these impacts on other receptors are provided in the chapters listed in **Table 7-44**.

Table 7-44 Inter-topic relationships

Topic and description	**Related Chapter**	**Where addressed in this Chapter**	**Rationale**
Marine Water and Sediment Quality	Chapter 8	**Sections 7.7.5.1, 7.7.5.3, 7.7.5.5, 7.7.7.1, 7.7.7.3, 7.7.7.5**	Changes in certain metocean conditions, morphological features or coastal processes have been identified in this Chapter, with their significance on marine water and sediment quality assessed in **Chapter 8, Marine Water and Sediment Quality**
Benthic and Intertidal Ecology	Chapter 9	**Sections 7.7.5.1, 7.7.5.2, 7.7.5.3, 7.7.5.4, 7.7.5.5, 7.7.5.6, 7.7.5.7, 7.7.6.8, 7.7.7.1, 7.7.7.2, 7.7.7.3, 7.7.7.4, 7.7.7.5, 7.7.7.6, 7.7.7.7.**	Changes in certain metocean conditions, morphological features or coastal processes have been identified in this Chapter, with their significance on benthic and inter-tidal ecology assessed in **Chapter 9, Benthic and Intertidal Ecology**
Fish and Shellfish Ecology	Chapter 10	**Sections 7.7.5.1, 7.7.5.2, 7.7.5.3, 7.7.5.4, 7.7.5.5, 7.7.5.6, 7.7.5.7, 7.7.6.8, 7.7.7.1, 7.7.7.2, 7.7.7.3, 7.7.7.4, 7.7.7.5, 7.7.7.6, 7.7.7.7.**	Changes in certain metocean conditions, morphological features or coastal processes have been identified in this Chapter, with their significance on fish and shellfish ecology assessed in **Chapter 10, Fish and Shellfish Ecology**

7.7.10. Interactions

318. The impacts identified and assessed in this chapter have the potential to interact with each other, which could give rise to synergistic impacts as a result of that interaction. The worst case impacts assessed within the chapter take these interactions into account and for the impact assessments are considered conservative and robust. For clarity the areas of interaction between impacts are presented in **Table 7-45** for construction/decommissioning and **Table 7-46** for operational impacts, along with an indication as to whether the interaction may give rise to synergistic impacts.

Table 7-45 Potential Interaction Between Metocean and Coastal Processes Impacts During Construction / Decommissioning

Potential interaction between impacts							
Construction / Repowering / Decommissioning	1: Changes in Suspended Sediment Concentrations During Foundation Installation / Device and Hub Removal in the Project	2: Changes in Sea Bed Level (Morphology) Due to Deposition During Foundation Installation / Device and Hub Removal in the Project	3: Changes in Suspended Sediment Concentrations During Offshore Export Cable Installation / Removal (including Nearshore and Landfall)	4: Changes in Sea Bed Level Due to Offshore Cable Installation / Removal (including Nearshore and Landfall)	5: Changes in Suspended Sediment Concentrations During Inter-Array Cable Installation / Removal	6: Changes in Sea Bed Level Due to Inter-Array Cable Installation / Removal	7: Changes in Sea Bed Level Due to Indentations in the Seabed

7.8. SUMMARY

319. As sediment plumes and sediment deposition will be governed by the axis of the tidal flows, there is limited potential for the sediment deposited from different turbine locations to coalesce and remain on the sea bed in any measurable magnitude within this area of strong tidal currents. Rather, deposited sediments would be very quickly re-suspended and redistributed across a wide area in low (immeasurable) quantities.

320. Due to the predominance of exposed bedrock on the sea bed, with occasional gravel cobbles and boulders, the Project will not cause significant changes in bed levels. In areas where a sand ridge is present (in the north of the Project) or where megaripples are present (in the south and southwest of the Project), there will be local effects on the sand surface. However, due to the high tidal energy environment across these areas, any depressions are likely to become rapidly re-worked following removal. Furthermore, these effects will be highly localised, one-off and temporary in duration.

321. Consideration of the potential effects of the Project is carried out over the following spatial scales:

- Near-field: the area within the immediate vicinity (tens or hundreds of metres) of the Project and along the offshore ECC; and
- Far-field: the wider area that might also be affected indirectly by the Project (e.g. due to disruption of waves, tidal currents or sediment pathways).

322. The magnitude of effect associated with these works have been assessed as being **negligible** to **medium** for near-field effects and **negligible** for far-field effects (**Table 7-47**).

323. **Chapter 7, Metocean Conditions and Coastal Processes** also identifies potential effects/changes on marine physical processes for which the receptor is considered in other Chapters (e.g. **Chapter 8, Marine Water and Sediment Quality** and **Chapter 9, Benthic and Intertidal Ecology**).

Table 7-47 Summary of potential impacts identified for metocean and coastal processes

Potential Effect	Scale	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Construction / Repowering Phase						
Effect 1: Changes in suspended sediment concentrations due to foundation installation in the Project	Near-field	Low	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 2: Changes in sea bed level (morphology) due to deposition during foundation installation in the Project	Near-field	Low	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 3: Changes in suspended sediment concentrations during offshore export cable installation (including nearshore) (construction only)	Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Low (sand ridge) to Negligible (elsewhere)
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 4: Changes in sea bed level due to offshore export cable installation (construction only)	Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 5: Changes in suspended sediment concentrations during inter-array cable installation	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 6: Changes in sea bed level due to inter-array cable installation	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 7: Changes in sea bed level (morphology) due to indentations during installation in the Project	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	No effect	Negligible	Negligible	Negligible	Negligible
Operational Phase						
Effect 1: Changes to the tidal regime due to the presence of structures in the Project	Device	Medium	High	Medium	Negligible	Medium
	Near-field	Low - Medium	High	Medium	Negligible	Low - Medium
	Far-field	Negligible	High	Medium	Negligible	Negligible

Potential Effect	Scale	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Effect 2: Changes to the wave regime due to the presence of structures in the Project	Device	Medium	High	Medium	Negligible	Medium
	Near-field	Low	High	Medium	Negligible	Low
	Far-field	Negligible	High	Medium	Negligible	Negligible
Effect 3: Changes to the sediment transport regime due to the presence of structures in the Project	Device	Low	High	Medium	Negligible	Low
	Near-field	Negligible	High	Medium	Negligible	Negligible
	Far-field	Negligible	High	Medium	Negligible	Negligible
Effect 4: Loss of sea bed morphology due to the footprint of structures in the Project	Near-field (direct footprint)	Low	High	Medium	Negligible	Low
	Far-field	No change	No change	No change	No change	No change
Effect 5: Morphological and sediment transport effects due to cable protection measures for offshore export cables (including nearshore and at the coastal landfall)	Near-field	Negligible	High	Medium	Negligible	Negligible
	Far-field	Negligible	High	Medium	Negligible	Negligible
Effect 6: Morphological and sediment transport effects due to cable protection measures for inter-array cables	Near-field	Negligible	High	Medium	Negligible	Negligible
	Far-field	Negligible	High	Medium	Negligible	Negligible
Effect 7: Changes in sea bed level (morphology) due to maintenance during maintenance in the Project	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	No effect	Negligible	Negligible	Negligible	Negligible
Repowering / Decommissioning Phase						
Effect 1: Changes in suspended sediment concentrations due to device and hub removal	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 2: Changes in sea bed level due to device and hub removal	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible

Potential Effect	Scale	Scale	Duration	Frequency	Reversibility	Magnitude of Effect
Effect 3: Changes in suspended sediment concentrations during offshore export cable removal (including nearshore and at the coastal landfall) (decommissioning only)	Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Low (sand ridge) to Negligible (elsewhere)
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 4: Changes in sea bed levels due to removal of the offshore export cables (decommissioning only)	Near-field	Low (sand ridge) to Negligible (elsewhere)	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 5: Changes in suspended sediment concentrations during removal of parts of the inter-array cables	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 6: Changes in sea bed levels due to removal of parts of the inter-array cables	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	Negligible	Negligible	Negligible	Negligible	Negligible
Effect 7: Changes in sea bed level (morphology) due to indentations during decommissioning in the Project	Near-field	Negligible	Negligible	Negligible	Negligible	Negligible
	Far-field	No effect	Negligible	Negligible	Negligible	Negligible

WFD	Water Framework Directive

GLOSSARY OF TERMINOLOGY

Bathymetry	Topography of the sea bed
Beach	A deposit of non-cohesive sediment (e.g. sand, gravel) situated on the interface between dry land and the sea (or other large expanse of water) and actively 'worked' by present-day hydrodynamic processes (i.e. waves, tides and currents) and sometimes by winds
Contaminant	A polluting substance within the sediment or water column
Current	Flow of water generated by a variety of forcing mechanisms (e.g. waves, tides, wind)
Ebb tide	The falling tide, immediately following the period of high water and preceding the period of low water
Fetch	The distance travelled by wind or waves across open water
Flood tide	The rising tide, immediately following the period of low water and preceding the period of high water
Gravel	Loose, rounded fragments of rock larger than sand but smaller than cobbles. Sediment larger than 2 mm (as classified by the Wentworth scale used in sedimentology)
Habitat	The environment of an organism and the place where it is usually found
Intertidal	Area on a shore that lies between Lowest Astronomical Tide (LAT) and Highest Astronomical Tide (HAT)
Megaripples	Bedforms with a wavelength of 0.6 to 10.0m and a height of 0.1 to 1.0m. These features are smaller than sand waves but larger than ripples
Neap tide	A tide that occurs when the tide-generating forces of the sun and moon are acting at right angles to each other, so the tidal range is lower than average
Nearshore	The zone which extends from the swash zone to the position marking the start of the offshore zone (~20m)
Numerical modelling	Refers to the analysis of coastal processes using computational models
Offshore	Area to seaward of nearshore in which the transport of sediment is not caused by wave activity
Sand	Sediment particles, mainly of quartz with a diameter of between 0.063mm and 2mm. Sand is generally classified as fine, medium or coarse
Scour	The erosion of sediment away from tan area as a result of the flow of water.
Sediment	Particulate matter derived from rock, minerals or bioclastic matter
Sediment transport	The movement of a mass of sediment by the forces of currents and waves
Semi-diurnal	Where two high and two low tides of approximately equal size occur every lunar day

Shallow water	Commonly, water of such depth that surface waves are noticeably affected by bottom topography. It is customary to consider water of depths less than half the surface wave length as shallow water
Significant wave height	The average height of the highest of one third of the waves in a given sea state
Spring tide	A tide that occurs when the tide-generating forces of the sun and moon are acting in the same directions, so the tidal range is higher than average
Surge	Changes in water level as a result of meteorological forcing (wind, high or low barometric pressure) causing a difference between the recorded water level and the astronomical tide predicted using harmonic analysis
Suspended sediment	The sediment moving in suspension in a fluid kept up by the upward components of the turbulent currents or by the colloidal suspension
Tidal current	The alternating horizontal movement of water associated with the rise and fall of the tide
Tidal range	Difference in height between high and low water levels at a point
Tide	The periodic rise and fall of the water that results from the gravitational attraction of the moon and sun acting upon the rotating earth
Water catchment	An area where water is collected by the natural landscape, eventually flowing to a river, lake, ocean or groundwater system
Wave height	The vertical distance between the crest and the trough

8. MARINE WATER AND SEDIMENT QUALITY

8.1. INTRODUCTION

1. Menter Môn Morlais Limited (Menter Môn) proposes the development of 240 MW of tidal generating capacity within the Morlais Demonstration Zone (MDZ). The development of the Morlais Project (the Project) will support the development of renewable energy technology objectives of the Anglesey and Gwynedd Joint Local Development Plan (JLDP), providing a consented tidal technology commercial demonstration zone. The Project will also provide opportunities for the local communities via direct employment and support of the local supply chain.

2. The development of the Project will provide a demonstration zone, specifically designed for the installation and commercial demonstration of multiple arrays of tidal energy devices. The Project will include communal infrastructure for tidal technology developers which provides a shared route to the cable landfall point via nine export cables, an onshore landfall substation, and an onshore electrical cable route to the existing electricity network via a grid connection substation (see **Chapter 4, Project Description**).

3. This chapter provides a summary description of key aspects relating to existing marine water and sediment quality, followed by an assessment of the magnitude and significance of the effects on the baseline conditions resulting from the construction, operation and decommissioning of the Project, as well as those effects resulting from cumulative interactions with other existing or planned projects.

4. This chapter has been prepared by MarineSpace Ltd on behalf of Menter Môn.

8.2. POLICY, LEGISLATION AND GUIDANCE

5. The principal European and International policy and legislation documents used to inform the assessment of potential impact on marine water and sediment quality include:

- Directive 2000/60/EC of the European Parliament and of the Council establishing a framework for the Community action in the field of water policy (the Water Framework Directive);
- Directive 2008/56/EC establishing a framework for community action in the field of marine environmental policy (Marine Strategy Framework Directive);
- Directive 76/464/EEC Water pollution by discharges of certain dangerous substances (Dangerous Substances Directive) and Priority Substances Directive (2008/105/EC);
- Directive 2006/7/EC concerning the management of bathing water quality and repealing Directive 76/160/EEC (the Bathing Waters Directive);
- Directive 2006/113/EC on the quality required of shellfish waters (The Shellfish Waters Directive);
- The International Convention for the Prevention of Marine Pollution by Ships (MARPOL Convention) 73/78;

- Canadian Sediment Quality Guidelines for the Protection of Aquatic Life (Canadian Council of Ministers of the Environment, 2002); and
- Cefas Action Levels for the disposal of dredged material.

8.2.1. National Policy Statements

6. The Project is seeking consent for a Transport and Works Act Order from the Welsh Ministers and a Marine Licence from Natural Resources Wales (NRW). Although this Project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts on marine water and sediment quality for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to marine water and sediment quality include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011a); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011 (DECC, 2011b).

7. Details of specific policies within EN-1 and EN-3 used to inform this assessment are provided in **Table 8-1** below. The specific assessment requirements for marine water and sediment quality are detailed, together with an indication of the paragraph numbers of the chapter where each is addressed.

Table 8-1 NPS EN-1 and EN-3 Assessment Requirements Relevant to Marine Water and Sediment Quality

NPS Requirement	NPS Reference	ES Reference
Infrastructure development can have adverse effects on the water environment, including transitional waters and coastal waters. During the construction, operation and decommissioning phases, discharges would occur. There may also be an increased risk of spills and leaks of pollutants to the water environment. These effects could lead to adverse impacts on health or on protected species and habitats and could, in particular, result in surface waters, ground waters of protected areas failing to meet environmental objectives established under the Water Framework Directive	EN-1 Paragraph 5.15.1	Potential impacts of the Project on water quality are assessed in **Section 8.6** and in the Water Framework Directive (WFD) Compliance Assessment found in **Appendix 8.1** (**Volume III**). Impacts to habitats and species are assessed in Chapter 10 Benthic and Intertidal Ecology, Chapter 11 Fish and Shellfish Ecology and Chapter 12 Marine Mammals.
Where the project is likely to have adverse effects on the water environment, the application should undertake an assessment of the existing status of, and impacts of the proposed project, on water quality, water resources and physical characteristics of the water environment as part of the Environmental Statement or equivalent	EN-1 Paragraph 5.15.2	The existing baseline is presented in **Section 8.5** and the baseline for relevant WFD marine bodies is provided in **Appendix 8.1** (**Volume III**).
The existing quality of waters affected by the proposed project and the impacts of the proposed project on water quality, noting any relevant existing discharges, proposed new discharges and proposed	EN-1 Paragraph 5.15.3	The existing baseline is presented in **Section 8.5** and the baseline for relevant WFD marine bodies is

NPS Requirement	NPS Reference	ES Reference
changes to discharges. Existing physical characteristics of the water environment (including quantity and dynamics of flow) affected by the proposed project and any impact of physical modifications to these characteristics; and any impacts of the proposed project on waterbodies or protected areas under the Water Framework Directive		provided in **Appendix 8.1** (**Volume III**).
The construction, operation and decommissioning of offshore energy infrastructure can affect marine water quality through the disturbance of sea bed sediments or the release of contaminants with subsequent indirect effects on habitats, biodiversity and fish stocks.	EN-3 Paragraph 2.6.189	Potential impacts during construction are assessed in **Section 8.6.4**.
Where the project is likely to have effects on water quality or resources the applicant should undertake an assessment as required in EN-1, Section 5.15.	EN-3 Paragraph 2.5.85	Potential impacts of the project on water quality are assessed in **Section 8.6** and in the Water Framework Directive (WFD) Compliance Assessment found in **Appendix 8.1** (**Volume III**).

8.2.2. Marine Policy Statement

8. The Marine Policy Statement (MPS) adopted by all UK administrations in March 2011 provides the policy framework for the preparation of marine plans and establishes how decisions affecting the marine area should be made in order to enable sustainable development. The MPS sets out a vision of having 'clean, healthy, safe, productive and biologically diverse oceans and seas' by supporting the development of Marine Plans. It also sets out the framework for environmental, social and economic considerations that need to be considered in marine planning.

8.2.3. Wales National Marine Plan

9. By adopting the MPS, the Welsh Government committed to the requirement to introduce Marine Plans for Wales.

10. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the Welsh National Marine Plan (WNMP). The Plan is being developed in accordance with the Marine and Coastal Access Act (MCAA) 2009, the MPS and the Maritime Spatial Planning Directive, a draft version has been issued for consultation (discussed further in **Chapter 2, Policy and Legislation**).

11. Objective 10 of the WNMP, "to maintain and enhance the resilience of marine ecosystems and the benefits they provide in order to meet the needs of present and future generations", is of relevance to this chapter as this covers policies and commitments on the wider ecosystem, as set out in the MPS including those to do with the Marine Strategy Framework Directive and the Water Framework Directive, as well as other environmental, social and economic considerations.

12. **Table 8-1** sets out national and regional policies which are particularly relevant to the Project.

Table 8-2 National and Regional Policy Requirements Relevant to Marine Water and Sediment Quality

Policy Description	Reference	ES Reference
MPS		
Developments and other activities at the coast and at sea can have adverse effects on transitional waters, coastal waters and marine waters. During the construction, operation and decommissioning phases of developments, there can be increased demand for water, discharges to water and adverse ecological effects resulting from physical modifications to the water environment. There may also be an increased risk of spills and leaks of pollutants into the water environment and the likelihood of transmission of invasive non-native species, for example through construction equipment, and their impacts on ecological water quality need to be considered.	Section 2.6.4.1	An assessment of potential impacts arising from the construction, operation and decommissioning of the Project is located in **Section 8.6.4**, **8.6.5** and **8.6.6**, respectively.
Draft WNMP		
Proposals should demonstrate that they: avoid the deliberate introduction of litter into the marine plan area; and minimise the risk of accidental release.	ENV_04: Marine Litter	Impacts through accidental spillage are assessed in Sections **8.6.4.4**., **8.6.5.1** and **8.6.6.2**.
Proposals should demonstrate that they have considered their potential air and water quality impacts and should, in order of preference: a) avoid adverse impacts; and/or b) minimise adverse impacts where they cannot be avoided; and/or c) mitigate adverse impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding.	ENV_06: Air and water quality	An assessment of potential impacts arising from the construction, operation and decommissioning of the Project is located in **Section 8.6.4**, **8.6.5** and **8.6.6**, respectively.
Proposals should minimise their risk of marine pollution incidents.	SOC_03: Marine pollution incidents	Impacts through accidental spillage are assessed in Sections **8.6.4.4**., **8.6.5.1** and **8.6.6.2**.
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative impacts are assessed in **Section 8.6.7** and in **Chapter 26**
Anglesey and Gwynedd Joint Local Development Plan (JLDP)		
Where appropriate, that the proposal does not have a significant unacceptable effect on the quality and supply of water	AND 3: Other Renewable Energy and Low Carbon Technologies	The impacts to marine water and sediment quality are assessed as minor to negligible and are summarised in **Section 8.7**, **Table 8-17**
It does not cause unacceptable harm to: i. water quality	AMG 4: Coastal Protection	

Policy Description	Reference	ES Reference
Wellbeing of Future Generations (Wales) Act 2015		
A nation which maintains and enhances a biodiverse natural environment with healthy functioning ecosystems that support social, economic and ecological resilience and the capacity to adapt to change (for example climate change).	A resilient Wales	The Project is assessed to have minor to negligible impacts on marine water and sediment quality (**Section 8.6**) while providing a source of renewable energy to communities.

8.2.4. The Water Framework Directive (WFD)

13. The WFD commits EU member states to achieve good quantitative and qualitative status of all water bodies. In the UK, an integrated approach to the management of all freshwater bodies, groundwaters, transitional (estuarine) and coastal waters at the river basin level has been adopted.

14. The overall requirement of the WFD is that all waterbodies must achieve Good Ecological Status by 2027, with interim targets in 2015 and 2021. It also requires that environmental objectives be set for all waterbodies to either maintain Good Status, or to move towards Good Status if a waterbody is currently failing its target. Under all conditions, it requires that there should be no deterioration in status.

15. Ecological status is assessed against a scale of high, good, moderate, poor or bad, with 'High' denoting largely undisturbed conditions and the other classes representing a deterioration from the undisturbed condition. The ecological status classification for the water body, and the confidence in this, is determined from the worst scoring quality element.

16. River Basin Management Plans (RBMPs) developed for each River Basin District (RBD) set out the current status classification of all waterbodies, as well as the objectives and actions required to maintain or improve the current Status of each waterbody. The Project is located within the Western Wales River Basin District.

17. At its nearest point the MDZ is located 0.5 km from the west coast of Holy Island, Anglesey, and falls within the Caernarfon Bay North WFD coastal water body which currently has an overall Good status, with a Good chemical status and a Good ecological status.

8.2.5. Marine Strategy Framework Directive

18. The objective of the Marine Strategy Framework Directive (MSFD) is to achieve ''good environmental status'' in Europe's seas by 2020, and to protect the resources upon which marine-related economic and social activities depend.

19. The MSFD enshrines, in a legislative framework, the ecosystem approach to the management of human activities having an impact on the marine environment, in order to enable the sustainable use of the marine environment and to safeguard its use for future generations.

20. The MSFD establishes European marine regions and sub-regions on the basis of geographical and environmental criteria and requires each Member State to develop a strategy for its marine waters (or Marine Strategy). In addition, because the MSFD follows an adaptive management approach, the Marine Strategies must be kept up-to-date and reviewed every six years.

21. In coastal waters out to 1 nm, both the WFD and the MSFD apply, however, in coastal waters the MSFD only applies for aspects of good environmental status that are not already addressed by the WFD.

8.2.6. The Dangerous Substances Directive and the Priority Substances Directive

22. The Dangerous Substances Directive and its associated Directives are concerned with controlling discharges that may contain dangerous substances that may reach inland, coastal and territorial waters.

23. The Dangerous Substances Directive set specific emission limit values and quality objectives for 17 substances (List I) in five specific directives, also called ‘daughter’ directives.

24. Some of these Environmental Quality Standards (EQS) have now been superseded by standards established by the Priority Substances Directive 2008/105/EC. Where this is not the case, limit values and environmental quality standards set by the ‘daughter’ Directives remain valid.

25. The Priority Substance Directive is implemented in England and Wales by the River Basin District Typology, Standards and Groundwater Threshold Values (Water Framework Directive) (England and Wales) Directions 2010. Compliance with these standards forms the basis of good surface water chemical status under the WFD.

26. The EQS under the Dangerous Substances Directive and Priority Substances Directive for selected List I substances are shown in **Table 8-3**.

Table 8-3 Environmental Quality Standards for Selected List I Substances

Substance	EQS Type	EQS under Priority Substances Directive (annual average, µg/l)	EQS under Dangerous Substances Directive (annual average, µg/l)
Arsenic (dissolved)	Annual average	-	25
Chromium (dissolved)	Annual average	-	15
Copper (dissolved)	Annual average	-	5
Lead (dissolved)	Annual average	7.2	25
Nickel (dissolved)	Annual average	20	30
Tributyl tin (TBT)	Maximum concentration	0.0002	0.002
Zinc (total)	Annual average	-	40

27. The EQSs for selected List II substances, based on data from the EA (2011) are shown in **Table 8-4** and includes the relevant EQSs under the Priority Substances Directive (where applicable).

Table 8-4 Selected List II Environmental Quality Standards (EA, 2011)

Substance	EQS Type	EQS under Priority Substances Directive (annual average, µg/l)	EQS under Dangerous Substances Directive (annual average, µg/l)
Mercury (dissolved)	Annual average	0.05	0.3
Cadmium (dissolved)	Annual average	0.2	2.5
HCH (Lindane)	Annual average	0.002	0.02
Total DDT	Annual average	0.025	0.025
ppDDT	Annual average	0.01	0.01
Pentachorophenol	Annual average	0.4	2
Aldrin	Annual average	Σ = 0.01	0.01
Dieldrin	Annual average	Σ = 0.01	0.01
Endrin	Annual average	Σ = 0.01	0.005
Isodrin	Annual average	Σ = 0.01	0.005
Total 'Drins'	Annual average	-	0.03
Hexachlorobenzene	Annual average	0.01	0.03
Hexachlorobutadiene	Annual average	0.1	0.1
Carbon tetrachloride	Annual average	12	12
Chloroform	Annual average	-	12
1,2-dichloroethane	Annual average	10	10
Trichloroethyleme	Annual average	10	10
Perchloroethylene	Annual average	-	10
Trichlorobenzene	Annual average	0.4	0.4

8.2.7. Bathing Waters Directive

28. The Bathing Water Directive is implemented through the Bathing Waters Regulations 2008. Member States must monitor bathing waters every year and the monitoring calendar should provide for at least four samples to be taken per season (except where the season is very short or where there are special geographic constraints). The sampling interval should not be longer than one month. Upon the monitoring results gathered in four years, Member States should assess the bathing waters at the end of every season. A shorter period may be acceptable in some cases.

29. The Environment Agency (EA) monitors and assesses bathing water quality at each designated bathing water site in England and Wales between May and September.

30. Under the revised Bathing Waters Directive (2006/7/EC) more stringent water quality standards have been set, and a stronger emphasis placed on beach management. The bacterial parameters listed above have been replaced by tests for:

- Escherichia coli; and
- Intestinal enterococci.

31. Given that bathing water is measured by testing for the above parameters and this Project has no pathway to introduce such bacterial elements, this has been scoped out of the assessment.

8.2.8. Shellfish Waters Directive

32. This Directive concerns the quality of shellfish waters and applies to those coastal and brackish waters designated by the Member States as needing protection or improvement in order to support shellfish (bivalve and gastropod molluscs) life and growth and thus to contribute to the high quality of shellfish products directly edible by man.

33. The parameters applicable to the waters designated by the Member States are listed in Annex I.

8.2.9. MARPOL Convention 73/78

34. The International Convention for the Prevention of Pollution from Ships, 1973 as modified by the Protocol of 1978 (MARPOL 73/78) was developed by the International Maritime Organization in an effort to minimize pollution of the oceans and seas, including dumping, oil and air pollution. The UK is a signatory to the MARPOL Convention 73/78.

35. All ships flagged under countries that are signatories to MARPOL are subject to its requirements, regardless of where they sail; and member nations are responsible for vessels registered on their national ship registry.

36. The objective of this convention is to preserve the marine environment in an attempt to completely eliminate pollution by oil and other harmful substances and to minimize accidental spillage of such substances.

8.2.10. International and National Sediment Quality Standards

8.2.10.1. Canadian Sediment Quality Guidelines for the Protection of Aquatic Life (Canadian Council of Ministers of the Environment (CCME), 2002).

37. Canadian sediment guidelines for the protection of aquatic life were developed under the auspices of the Canadian Council of Ministers of the Environment (CCME) to help set targets for sediment quality that would sustain long-term aquatic ecosystem health. The guidelines were developed from the available scientific information on the biological effects of sediment-associated chemicals.

38. The sediment quality guidelines are numerical concentrations or narrative statements that, unless otherwise specified, refer to the total concentration of a substance in surficial sediments (i.e. the upper few centimetres) on a dry weight basis (e.g. mg/kg dry weight).

39. They are not statutory standards and are based on the protection of pristine environments. There are two assessment levels - the Threshold Effect Level (TEL) is the lower of the levels and represents the concentration below which adverse biological effects are expected to occur only rarely. The higher level, the Probable Effect Level (PEL), defines a concentration above which adverse effects may be expected in a wider range of organisms.

40. Selected Canadian guidelines are presented in **Table 8-5**.

Table 8-5 Selected Canadian Sediment Quality Guideline Values (taken from CCME, 2002)

Contaminant	Units	TEL	PEL
As	mg/kg	7.24	41.6
Cd	mg/kg	0.7	4.2
Cr	mg/kg	52.3	160
Cu	mg/kg	18.7	108
Hg	mg/kg	0.13	0.7
Pb	mg/kg	30.2	112
Zn	mg/kg	124	247
Acenaphthene	µg/kg	6.71	88.9
Acenaphthylene	µg/kg	5.87	128
Anthracene	µg/kg	46.9	245
Benz(a)anthracene	µg/kg	74.8	693
Benzo(a)pyrene	µg/kg	88.8	763
Chrysene	µg/kg	108	846
Dibenz(a,h)anthracene	µg/kg	6.22	135
Fluoranthene	µg/kg	113	1494
Fluorene	µg/kg	21.2	144
Napthalene	µg/kg	34.6	391
Phenanthrene	µg/kg	86.7	544
Pyrene	µg/kg	153	1398

8.2.10.2. Cefas Action Levels for the Disposal of Dredged Material (Cefas, 2000)

41. One means of assessing the pollution potential associated with marine sediment is to compare their analysed contaminant levels with the ‘Action Levels’ for contaminants as defined by Centre for Environment, Fisheries and Aquaculture Science (Cefas). However, these are not statutory standards.

42. Action Levels are used by Cefas as part of a ‘weight of evidence’ approach to assessing sediment contamination, and the suitability for the disposal at sea of such sediment. For Cefas’ decision making process these values are used in conjunction with a range of other assessment methods, including bioassays, the disposal site characteristics and other relevant data.

43. In general, contaminant levels in sediment below Action Level 1 are of no concern to Cefas and unlikely to influence the licensing decision, while sediment with contaminant levels above Action Level 2 is generally considered unsuitable for sea disposal. Where contaminant levels lie between Action Levels 1 and 2, further consideration must be made before disposal, but there is no prohibition that sediment exceeding Action Level 1 for contaminants is unsuitable for further use or disposal at sea. Fine (muddy) sediments have a higher risk of containing contaminants (due to a relatively large surface area and greater cation exchange capacity) than coarser sediments, such as sand and gravel.

44. Selected current Action Levels are set out in **Table 8-6**.

Table 8-6 Selected Cefas Action Levels

Contaminant / Compound	mg/kg Dry Weight (ppm)	mg/kg Dry Weight (ppm)
Arsenic	20	100
Mercury	0.3	3
Cadmium	0.4	5
Chromium	40	400
Copper	40	400
Nickel	20	200
Lead	50	500
Zinc	130	800
Orgotins; TBT DBT MBT	0.1	1
PCB's, sum of ICES 7	0.01	none
PCB's, sum of 25 congeners	0.02	0.2
*DDT	*0.001	
*Dieldrin	*0.005	

Levels marked with * were set in 1994

8.3. CONSULTATION

45. Consultation with statutory bodies and key stakeholders was undertaken through a formal Environmental Impact Assessment (EIA) scoping process for the Project. Key responses of relevance to marine water and sediment quality have been summarised in **Table 8-7**.

Table 8-7 Summary of Consultation Responses as a Result of Scoping, Relating to Marine Water and Sediment Quality

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping	The Scoping Report identifies marine water quality designations including bathing waters and a European Shellfish Water within the offshore scoping area and adjacent Holy Island coastal area. Table 7-2 (Potential impacts on marine sediment and water quality) of the Scoping Report identifies potential impacts but does not relate impacts to specific receptors such as designated sites for water quality. The ES should clearly identify and assess impacts to specific receptors where significant effects are likely. The ES should include figures that clearly depict the locations of such receptors.	See **Table 8-13**, which provides details of designated or sensitive sites within the vicinity of the MDZ and of relevance to the marine water and sediment quality assessment, and **Section 8.6** for the assessment.
Planning Inspectorate	2018 Scoping	Section 7.2.1.2 of the Scoping Report indicates the potential for contaminated sediments in the offshore area. The mobilisation of contaminants during construction has not been identified as a potential impact in Table 7-2 of the	**Section 8.6.4.3** assesses change in water quality due to release of

Consultee	Date/Document	Comment	Response
		Scoping Report, although it is noted that it has been identified as a potential impact on benthic ecology in Table 8-4. The Applicant should identify other receptors that may be significantly affected by the mobilisation of contaminants and if so, assess any impacts accordingly within the ES.	contaminated sediments.
Planning Inspectorate	2018 Scoping	Evidence should be provided within the ES to justify the assertion that any suspended sediments would be rapidly dispersed due to tidal flows, particularly in the nearshore and intertidal areas.	**Section 8.6.4.1** assesses change in water quality due to sediment plumes generated via foundation installation. Detailed information on tidal flows is provided in **Chapter 7, Metocean Conditions and Coastal Processes**.
Planning Inspectorate	2018 Scoping	Site-specific sediment contaminant sampling: It is recommended that the sampling programme is discussed and agreed with NRW.	No project-specific sediment contaminant sampling undertaken – See **Section 8.4.2.2**.
Planning Inspectorate	2018 Scoping	The Scoping Report has not detailed how the potential impacts will be assessed. The methodology must be detailed in the ES. It is considered that modelling will be required to predict the anticipated increase in suspended sediment from the Proposed Works. The ES should include details of the parameter inputs to the model and provide an explanation/justification of any worst case scenario that has been assumed.	Impact assessment methodology is included in **Section 8.4.3** and **Chapter 5, EIA Methodology**. Modelling has been used to assess the baseline hydrodynamic regime and the impacts from the Proposed Works on the baseline hydrodynamic regime. A description of this modelling process is provided in **Appendix 7.1** (**Volume III**). The results from the baseline understanding and

Consultee	Date/Document	Comment	Response
			hydrodynamic modelling have then been used to inform the assessment (**Section 8.6**).
NRW	2018 Scoping	In section 7.2.1.1 there is reference to the bathing water quality for eight beaches in the MDZ coastal area and reference to one designated European Shellfish Water. There is, however, no inclusion of the Water Framework Directive (WFD) existing water body status for the coastal water bodies within the demonstration zone. This must be included in the ES.	See **Table 8-13**, which provides details of all designated or sensitive sites within the vicinity of the MDZ (including coastal water bodies) of relevance to the marine water and sediment quality assessment.
NRW	2018 Scoping	The demonstration zone is located at its nearest point, 0.5 km (0.27 nautical miles) from the west coast of Holy Island Anglesey and falls within the Caernarfon Bay North WFD coastal water body which currently has an overall Good status, with a Good chemical status and a good ecological status. A Preliminary WFD Assessment report must be prepared by the applicant and submitted with the Marine Licence application and, where required, a detailed WFD Compliance Assessment Report should be undertaken.	A WFD compliance assessment report has been produced, please see **Appendix 8-1** (**Volume III**).
NRW	2018 Scoping	Contaminated sediments could be present in the demonstration zone and investigations should be carried out to determine the level of contaminated sediments particularly in areas where sediment may be disturbed into suspension during the construction phase i.e. installation of devices and the cable laying activities which could potentially release contaminants into the water column. We note your comment (section 7.2.3) “It is likely that site-specific sediment contaminant sampling would also be undertaken during the EIA” and advise that this activity is carried out.	No project-specific sediment contaminant sampling undertaken - See **Section 8.4.2.2**.
NRW	2018 Scoping	There has been no inclusion of tidal current data in the demonstration zone which shows the magnitude and direction of flow over the zone to substantiate the assumption that the suspended sediments would rapidly disperse. We agree that in fast flowing currents, dispersion of suspended sediments could occur rapidly and the	An assessment of the effects on the tidal regime have been included in **Chapter 7, Metocean Conditions and Coastal Processes**.

Consultee	Date/Document	Comment	Response
		potential for smothering would be reduced as a result (table 7.2). However, there is no baseline evidence presented in the metocean section that supports this assessment of impact. Further evidence should be presented in the ES to show the magnitude and direction of the tidal currents in the nearshore and intertidal areas which are often much smaller than those experienced offshore, and which may not be enough to promote rapid dispersion of suspended sediments and potential contaminants released through trenching activities over this zone.	
NRW	2018 Scoping	Section 7.2.3 states “baseline water quality conditions within the offshore scoping area. This would be done through a review of available literature”. It is unclear which baseline water quality conditions are being referred to. If the baseline water quality conditions are not adequately evidenced after review of available literature, further surveys should be carried out to inform the baseline characterisation.	There is suitable data on bathing water quality for nearby designated bathing beaches and these data have been used in this assessment (see **Section 8.5**) and the WFD compliance assessment (**Appendix 8-1, Volume III**).
NRW	2015 Scoping	The potential impacts on marine sediment are provided in Table 6.2 which we agree with, however, there is also potential for the release of contaminants into the water column if marine sediment is disturbed. This should be assessed in the EIA.	**Section 8.6.4.3** assesses change in water quality due to release of contaminated sediments.

8.4. METHODOLOGY

8.4.1. Study Area

46. The study area for marine water and sediment quality has a total area of 39.75 km², comprising the MDZ of 35 km², the export cable corridor (ECC) area of 4.75 km² and includes an intertidal area of 0.01 km² shared between the ECC and the onshore development area (ODA). The ECC connects the MDZ to the landfall location at Abraham’s Bosom on the west coast of Holy Island. The ECC encompasses much of the sea area to landward of the MDZ, to the landfall at Abraham’s Bosom.

8.4.2. Data Sources

8.4.2.1. Desk Study

47. The data and information presented in this section uses information collated for **Chapter 7, Metocean Conditions and Coastal Processes**. Data sources include information from existing

nearby projects, such as the Deep Green Holyhead Deep Project Phase I (0.5 MW) Environmental Statement (Minesto, 2016), as well as published literature. Baseline data and information have been collected from the following sources:

- Barne *et al*., 1995. Coasts and seas of the United Kingdom, Region 12 Wales;
- British Geological Survey (BGS) seabed sediment data;
- BGS Offshore Regional Report for the Irish Sea;
- Horizon Nuclear Power, 2018. Wylfa Newydd Project Water Framework Directive Compliance Assessment. 429pp;
- Horizon Nuclear Power, undated. Wylfa Newydd Project Disposal Site Characterisation Report. 227pp;
- Howarth, 2005. Technical report on the hydrography of the Irish Sea conducted as part of the Strategic Environmental Assessment (SEA) process; and
- Minesto, 2016. Deep Green Holyhead Deep Project Phase I (0.5 MW) Environmental Statement. 487pp.

8.4.2.2. Site-Specific Surveys and Reports

48. In addition to the general baseline data and information indicated in **Section 8.4.2** a number of site-specific surveys have also been used in this assessment (**Table 8-8**). Further details can be found in **Chapter 7, Metocean Conditions and Coastal Processes** of this ES.

Table 8-8 Data Sources

Data	Year	Coverage	Confidence	Notes
Geophysical Survey	2018	MDZ, buffer zone and Abraham's Bosom	High	High-resolution sea bed bathymetry, seabed texture and morphological features, and shallow geology using multibeam echosounder, side-scan sonar, and boomer (Partrac, 2018).
Subtidal Grab Sample Survey	2018	MDZ and buffer zone	High	Drop-down camera and five grab samples at selected suitable sites (Ocean Ecology, 2018).
Intertidal Survey	2018	Abraham's Bosom	High	Unmanned Aerial Vehicle (UAV) survey and intertidal walkover (Ocean Ecology, 2018).
Metocean Survey	2014	MDZ	High	Bottom-mounted Acoustic Doppler Current Profilers (ADCP) deployed for a continuous 40-day period in November and December 2014 at two locations.

49. With respect to any site-specific sediment contaminant sampling, following review of the local seabed conditions in the MDZ and ECC, it was clear that given the area's very high tidal energy and limited sediment cover, as well as the absence of any history of, or any apparent mechanism for, contaminant inputs, the potential for sediment contamination was low. In addition, the highly limited presence of sediment would limited opportunity for any sediment samples to be collected. Therefore, inclusion of contaminant sampling within project-specific EIA characterisation surveys was judged inappropriate and unlikely to be successful.

50. In practice, as indicated by initial review of the site, only limited sediment samples were able to be collected within the MDZ site during the summer 2018 survey, due to the absence of sediment cover for most of the site. These samples were of insufficient quality and quantity to have enabled any sediment contamination analysis.

51. Consideration has also been given to the outcome of recent sediment sampling for the adjacent Minesto project. This site is located much closer to the active Holyhead Deep marine disposal site (ISO40) than the MDZ and ECC and has seabed sediment present which might be expected to act as a sink for contaminants.

52. Analysis of samples for this project, collected by Minesto as part of their EIA studies in close proximity to the active disposal site, showed that levels of contamination in all the sediment samples were below Cefas AL1.levels (Minesto, 2016). Were sediment contamination to be an issue in this region, it would be more likely to occur in the Minesto site than the MDZ or ECC because of the greater proximity to the active disposal site and the larger amount of sediment cover compared to the MDZ and ECC.

8.4.3. Impact Assessment Methodology

53. This impact assessment follows the general methodology as set out in **Chapter 5, EIA Methodology**, of this ES.

54. The first stage in the assessment of potential impacts on marine water and sediment quality is to determine the baseline conditions of the marine water (i.e. the naturally occurring levels of contamination and concentrations of suspended sediments) and the sediments (in terms of physical properties and contamination). The physical properties of the sediments are important because fine muddy sediments have a higher risk of containing/taking up contaminants (due to a relatively large surface area and greater cation exchange capacity) than coarser sediments, such as sand and gravel.

55. Potential effects on marine water and sediment are then compared against existing baseline conditions and potential impacts are assessed against natural variation, the study area characteristics, spatial and temporal scales.

56. The EIA framework used in this assessment is based on the 'source-pathway-receptor' conceptual model process where the 'source' describes the origin of potential effects, and the 'pathway' describes the means by which the effect reaches the receiving sensitive 'receptor'. If the source, pathway or receptor is absent, no linkage exists and thus there will be no potential for an impact to occur.

8.4.3.1. Sensitivity

57. The sensitivity of a receptor is a measure of its ability to adapt to change, tolerate, and/or recover from potential impacts. The overall receptor sensitivity is therefore determined by a consideration of the receptor value, adaptability, tolerance and recoverability.

58. The sensitivity criterion also combines an assessment of the value of the receptor, which considers whether, for example, the receptor is rare, has protected or threatened status, has

importance at a local, regional, national or international scale, and in the case of biological receptors whether the receptor has a key role in the ecosystem function.

59. In order to define the sensitivity on marine water and sediment quality receptors, the criteria indicated in **Table 8-9** have been used.

Table 8-9 Definitions of the Sensitivity Levels for the Marine Water and Sediment Quality Receptors

Sensitivity	Definition
High	The marine water and sediment quality receptors support or contribute towards the designation or nationally important feature and have a very limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Medium	The marine water and sediment quality receptors support high biodiversity and have a limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Low	The marine water and sediment quality of the receptor have a high capacity to accommodate change to status, due, for example, to large relative size of the receiving water and capacity for dilution and flushing. Background concentrations of certain parameters may already exist.
Negligible	Specific marine water and sediment quality conditions are likely to be able to tolerate proposed change with very little or no impact upon the detectable baseline conditions

8.4.3.2. Magnitude

60. An assessment of the magnitude of effect is based on the consequences the effect has on marine water and sediment quality. The definitions of magnitude, specific to this assessment of marine water and sediment quality are indicated in **Table 8-10**.

Table 8-10 Definitions of the Magnitude Levels for the Marine Water and Sediment Quality Receptors

Magnitude	Description
High	Very significant changes to key characteristics of the marine water and sediment quality status of the receiving water feature. Water quality status degraded to the extent that a permanent or long-term change occurs.
Medium	Significant changes to key characteristics of the marine water and sediment quality status, taking account of the receptor volume, mixing capacity, flow rate, etc. Marine water and sediment quality status likely to take considerable time to recover to baseline conditions.
Low	Noticeable but not considered to be significant changes to the marine water and sediment quality status taking account of the receiving water features. Activity not likely to alter local status to the extent that water quality characteristics change considerably or EQSs are compromised.
Negligible	Although there may be some impact upon marine water and sediment quality status, activities predicted to occur over a short period. Any change to marine water and sediment quality status will be quickly reversed once activity ceases.

8.4.3.3. Impact Significance

61. Impacts are assessed by relating the magnitude of an effect to the sensitivity/value of the receptor, which in this case is marine water and sediment quality. The relationship is presented as a matrix, as shown in **Table 8-11**.

Table 8-11 Impact Assessment Matrix

		Negative Magnitude				Beneficial Magnitude			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

62. In the context of marine water and sediment quality, the impact significance categories in **Table 8-12** can be defined.

Table 8-12 Impact Significance Definitions

Impact Significance	Definition
Major	Very large or large change in marine water and sediment quality, both adverse or beneficial, which are likely to be important considerations at a regional or district level because they contribute to achieving national, regional or local objectives, or, could result in exceedance of statutory objectives and / or breaches of legislation.
Moderate	Intermediate change in marine water and sediment quality, which is likely to be important considerations at a local level.
Minor	Small change in marine water and sediment quality, which may be raised as local issue but is unlikely to be important in the decision-making process.
Negligible	No discernible change in marine water and sediment quality

63. For the purposes of the EIA, 'major' and 'moderate' impacts are significant in terms of the EIA regulations and have to be avoided or reduced through mitigation, where possible. In addition, whilst 'minor' impacts are not significant in their own right, they may contribute to significant impacts cumulatively or through interactions.

64. Where the potential for an accidental spillage is concerned, the assessment is based on the risk of a spill or other accidental pollution event occurring. This is considered in relation to control measures that are available to minimise the risk.

8.5. EXISTING ENVIRONMENT

8.5.1. Regional Context

65. The MDZ is situated west of Holy Island and Anglesey, in an offshore area known as the Holy Island Shelf. The Holy Island Shelf is identified as an inlier of Precambrian metamorphic bedrock fringed to the north and west southwest with Lower Palaeozoic (undivided) sedimentary strata (Jackson et al., 1995).

66. The seaward coastline of Holy Island is formed of hard rock cliffs, and small sandy bays. The northern coastline is also rocky but has significant development through the port town of Holyhead. East of Holyhead the rocky cliffs persist as far as Penrhos beach. The eastern coastline of Holy Island is characterised by the salt marshes and mud-flats of the Alaw Estuary.

67. This bedrock, like the bedrock on areas of Anglesey, is part of the Monian Supergroup, comprising Holy Island, New Harbour and Gwna Groups. It is thought to have formed more than 570 million years (Ma) ago, although there is some debate that the formation may extend into

the Cambrian (Gibbons, 1983; McIlroy and Horak, 2006). The Monian Supergroup comprises gneisses, schists and igneous rocks, overlain by extrusive igneous rocks (Jackson et al., 1995). The igneous rocks are mostly volcanic-arc types, although some, as with the Gwna Group, show affinities with ocean floor basalts (Jackson et al., 1995).

68. The Holy Island Shelf to the west and north of South Stack is cut by Anglesey dykes of Tertiary age, orientated north northwest to south southeast (Jackson et al., 1995). These dykes are thought to be igneous in origin (Dolerite) (BGS, 2017) formed during a period of regional extension in the Palaeocene, resulting from a major north-south uplift (Jackson et al., 1995) as part of the final breakup of Pangea and the early stages of the opening of the Atlantic Ocean.

69. The BGS (1990) Seabed Sediments chart of Anglesey indicates that much of the MDZ consists of this exposed bedrock substrate with only local and/or intermittent cover of mobile and lag sediment in the nearshore. The BGS (1990) indicates that, offshore, there is less potential for finer sediment as it is likely to have been winnowed out by strong tidal processes, leaving a coarser surficial sediment.

70. A number of statutory and non-statutory designated sites occur in the vicinity of the MDZ and are potentially relevant to this assessment. These are detailed in **Table 8-13** and shown in **Figure 8-1** (**Volume II**).

Table 8-13 Designated or Sensitive Sites Within the Vicinity of the MDZ and of Relevance to the Marine Water and Sediment Quality Assessment

Site Name	Designation	Relevance to Assessment	Distance from the MDZ (km)
Caernarfon Bay North	Coastal Water Body	Welsh Coastal Water Body	Partial overlap
Holyhead Bay	Coastal Water Body	Welsh Coastal Water Body	3.0
Porth Dafarch	Bathing Water	Bacterial water quality monitoring for public health	1.4
Trearddur Bay	Bathing Water	Bacterial water quality monitoring for public health	4.2
Anglesey Inland Sea Shellfish Sites	Bivalve mollusc production area	Shellfish Water	21.0
Borth Wen	Bathing Water	Bacterial water quality monitoring for public health	6.7
Silver Bay Rhoscolyn	Bathing Water	Bacterial water quality monitoring for public health	8.3
Church Bay	Bathing Water	Bacterial water quality monitoring for public health	10.0

Site Name	Designation	Relevance to Assessment	Distance from the MDZ (km)
Rhosneigr	Bathing Water	Bacterial water quality monitoring for public health	11.2
Maltraeth	Cockle Fishery	Shellfish Water	21.7

71. The MDZ lies in close proximity to two Welsh WFD Coastal Water Bodies – the eastern part of the MDZ overlaps the Caernarfon Bay North (GB621010380000) water body, while the Holyhead Bay (GB681010360000) water body is located approximately 3 km away from the MDZ at its nearest point (**Figure 8-1, Volume II**).

72. The Caernarfon Bay North water body is classified as having good status overall. Data reported by Horizon Nuclear Power (2018) show that biological quality elements are at good status (based on benthic invertebrates); the classification of physico-chemical quality elements is high (based on dissolved oxygen, copper and zinc); the hydromorphological supporting elements are classified as 'supports good' (based on morphology); and the chemical assessment is good (based on an assessment of priority substances).

73. There are six bathing water beaches along the west coast of Anglesey (**Figure 8-1, Volume II**), all of which meet the higher water quality standard and have consistently met the higher standard since 2010.

74. The water catchment areas have a mix of rural, residential and commercial use but are predominantly rural in nature. Water catchment areas typically have a low level of sewage and industrial run-off. Based on the classifications reviewed as part of this assessment, there are no known issues with agricultural run-off.

8.5.2. Physical Environment

8.5.2.1. Hydrodynamics

75. Tides within the MDZ are semi-diurnal, with a spring tidal range of up to 4.5 m. Tides enter the Irish Sea from the Atlantic Ocean through St George's Channel and the North Channel to the south and north respectively.

76. Tidal currents within part of the MDZ are characterised by the ADCP surveys from Sites 1 and 2 (**Table 8-14**). These data show that current velocities at the measurement locations are slightly lower towards the sea bed due to bed-friction, but all values recorded exhibit very high baseline current speeds.

Table 8-14 Peak Tidal Currents at Sites 1 and 2 within the MDZ (source: OpenHydro, 2015)

Height above sea bed	Peak Velocities on a Mean Spring Tide Site 1 (m/s)	Peak Velocities on a Mean Spring Tide Site 2 (m/s)
10 m	2.71	2.64
15 m	2.84	2.79

20 m	2.92	2.90

77. Current roses from Sites 1 and 2 (and shown in **Figure 7-11, Volume II**) show that at both sites the baseline current velocities are strongly aligned from just east of south to north-northwest. However, further north in the MDZ, the tidal currents flow around Holy Island (to the north on a flooding tide and to the south on an ebbing tide) along a more south-north and then (with progression north) south-southwest-north-northeast axis.

78. Tidal current speeds and directions were also predicted by the baseline numerical modelling undertaken by HR Wallingford (2017) and showed peak speeds are generally faster through the eastern parts of the sub-zones, reaching around 2.6 – 2.8 m/s in most areas, apart from the northernmost and southernmost sub-zones. The highest velocities within the MDZ are recorded just off Holy Island (4.0 m/s; as discussed within **Chapter 7, Metocean Conditions and Coastal Processes**). For the western parts of the sub-zones, peak speeds are lower, reaching around 2.2 – 2.6 m/s.

79. These data are supported by other studies, e.g. Minesto (2016) indicates that the peak depth averaged mean spring current speeds at the coastal margins of the North Channel are up to 3 m/s, while peak depth-averaged mean neap currents approach 1.5 m/s. Horizon Nuclear Power (Undated) also reports tidal velocities in excess of 2.5 m/s during spring tides. Horizon Nuclear Power (Undated) also reports that the tidal current velocity is relatively unvarying with depth, except near the seabed, and results in well mixed unstratified waters.

80. SEACAMS modelling, reported in Minesto (2016), shows that the bed shear stresses (the frictional force exerted on the seabed by the movement of water) within the MDZ for a 15 day simulation is between 6 N/m^2 at the western offshore boundary, increasing to approximately 22 N/m^2 at points closest to Holy Island. These bed shear stresses are sufficient to transport fine and medium sands, and help to explain the swept bedrock in much of the MDZ (see below and Partrac, 2018). The MDZ is, therefore, dispersive of fine sediments and sands, generally transporting them to the north-east.

81. As a result of the semi-enclosed nature of the Irish Sea, waves are mostly locally generated (Morlais, 2016). Horizon Nuclear Power (Undated) reports that predominant wave directions are from the southwest and west, with the highest frequency from the southwest. These waves also have the longest fetch distances.

82. The wave regime was characterised using data obtained from the Met Office at three locations northwest of the MDZ and show the dominant offshore wave direction is south-southwest to southwest (see **Chapter 7, Metocean Conditions and Coastal Processes** for more details). The annual mean significant wave height (SWH) for the area is 1.26 – 1.50 m, ranging from 0.76 – 1.00 m in the summer to 1.51 – 1.75 m in the winter (Atlas of UK Marine Renewable Energy Resources, 2008).

83. Potential bed sediment transport is dominated by the tidal flow because water depths are, typically, sufficiently large that wave energy does not reach the seabed. Minesto (2016) shows that bed shear stresses are dominated by tidal flows, but that under extreme wave conditions (e.g. 8 m waves and larger) some wave interaction with the seabed could occur.

8.5.2.2. Seabed Sediments

84. Seabed data across the MDZ, collected and interpreted by Partrac (2018) show that throughout most of the northern, central and eastern parts of the MDZ the surface is dominated by outcropping rock. Sandy gravels are considered to generally make up the sediment patches that overlie the rock; and the deeper, western part of the MDZ consists of a relatively uniform gravel or gravelly sand, with small areas of outcropping rock to the north and localised megaripples to the south. Along the northwestern boundary of the MDZ, an increase in grain size is interpreted, meaning the gravels that dominate the seabed may contain coarser material.

85. Three grab samples collected by Ocean Ecology Ltd (2018) from the offshore area returned gravelly sands and sandy gravels with very low fines content (one sample contained 1.9 % <63 µm, while the other two samples contained no sediments finer than 63 µm). The very low fines content is consistent with sediments present in high energy environments, where fine grained material is rapidly winnowed and transported away. Only three samples were able to be collected due to the generally hard rock, tidally-swept seabed.

86. Within the shallower bays, along the Holy Island coast, are deposits of finer sediments. Sediments in the bays generally consist of sandy gravel or coarse sand, and in the case of the shallow waters within 'Abraham's Bosom' the sediments become finer, being interpreted as consisting of fine sand. A grab sample collected within 'Abraham's Bosom' by Ocean Ecology Ltd (2018) returned a sample of moderately sorted medium sand, with a d50 of approximately 0.4mm and a low fines content (3.6 % <63 µm).

87. The seabed in the north of Anglesey is characterised by exposed bedrock, or bedrock thinly overlain by boulders and gravels in a patchy composition (Rees, 2005). The intertidal areas around Anglesey are extensive areas of relatively undisturbed habitats comprised of high energy rocky shores, sea cliffs, coastal heathlands and coastal grazing. The west of Anglesey, where the export cable will landfall, has substantial areas of exposed shores which are largely coastal cliff headlands with beaches comprise of moderate coarse sediments.

88. Boulders are identified by Partrac (2018) as occurring over almost the entire offshore area surveyed. These range in size between 0.2 m – 1.5 m. Further, within the subtidal and intertidal surveys conducted to support **Chapter 9, Benthic and Intertidal Ecology**, extensive areas of both stony reef and bedrock reef were recorded (Ocean Ecology Ltd, 2018). Bedrock and stony reefs are both types of rocky reef which occur where the bedrock or stable boulders and cobbles arise from the surrounding seabed. A stony reef is defined as an area which is comprised of coarse sediments with a diameter of greater than 64 mm (cobbles and boulders) that provide a hard substratum. A reef is defined as having relief from the seafloor and elevation is used as a criterion in its classification. Epifaunal communities of a potential reef are also key in the determination of reefiness, with percentage cover of fauna used as a determination criterion. Irving (2009) classification of reef requires an area of potential stony reef habitat to be greater than 25 m^2 to be classified as a reef.

89. The north east spreading along the eastern central area of the site to the south west of the MDZ were dominated by stony reefs, while the central and north east area of the site were recorded as bedrock reef areas. Within the south east of the site, there were several areas of patchy

bedrock reef observed, and likewise in the southwest there were areas of patch stony reefs. Within the intertidal zone, the immediate seabed is covered by an expanse of bedrock reef, tailing into stony/bedrock reef in the north east and south east of the site.

90. Partrac (2018) also identified a large sandwave feature was identified near to South Stack which extends to the northwest for approximately 1 km. Bed levels either side of this feature are approximately 8 to 10 m different in height either side of the ridge, with bed levels deeper on the southwest side. This ridge is generally symmetrical in profile. Several smaller ridge features run parallel to the main ridge, extending to the north-northeast.

8.5.2.3. Suspended Sediment Transport

91. Measurements of suspended sediment concentration were carried out generally across the Irish Sea during June and November 1997, and April and September 1998 at a total of 85 stations. Overall, suspended sediment concentrations were between 2.55 and 23 mg/l over the period (**Table 8-15**), although concentrations varied seasonally (Bowers *et al*., 2002). More specific to the sea bed off Anglesey, suspended sediment concentrations remain very low, reaching about 5mg/l in summer and 10 – 15 mg/l in winter.

Table 8-15 Concentration of Total Suspended Solids (mg/l) in the Irish Sea 1997 - 1998

	Min	**Max**	**Mean**
June 1997, 16 stations	3.73	14.18	6.57
November 1997, 17 stations	2.55	20.38	9.82
April 1998, 26 stations	3.30	23.00	10.27
September 1998, 26 stations	2.76	17.18	5.70

8.5.2.4. Marine Disposal Areas

92. Marine water and sediment quality can be affected by the presence of marine disposal sites. The MDZ is located close to the boundary of the currently active Holyhead Deep disposal site (ISO40). The MDZ is also close to two closed disposal sites, namely Holyhead South (IS041), and Holyhead East (IS042) (**Figure 8-2, Volume II**).

93. The currently active Holyhead North site lies 5 km northwest of Holy Island and extends over an area of approximately 28.8 km^2. Horizon Nuclear Power (undated) indicates that since Holyhead Deep was opened in 1983, licences have been granted for the disposal of both capital and maintenance dredge arisings.

94. Horizon Nuclear Power (undated) also indicates that, over the period of operation of Holyhead Deep, approximately 1.66 Mt (1.1 Mm^3) of sediment has been disposed of at the site. This helps set the context for the potential worst-case sediment resuspension calculations for the MDZ presented in **Section 8.6.4.1** and **8.6.4.2** of this chapter.

95. Minesto (2016) indicates that all recent (since at least 2009) dredge spoil disposal at the Holyhead Deep disposal site has been maintenance dredge material from Holyhead Port; and Potter (2014; reported in Minesto (2016)) determined that the material dredged from the harbour is in the silt range (i.e. 0.0039 to 0.0625 mm on the Wentworth scale (Wentworth, 1922)).

96. The sediment disposed of at Holyhead Deep is, therefore, much finer-grained than the bed sediments present in the MDZ and its associated cable corridor. This sediment, by virtue of its finer-grained nature, has a higher risk of containing contaminants (due to a relatively large surface area and greater cation exchange capacity) than coarser sediments, such as sand and gravel. In addition, its fine-grained nature means it will remain in suspension longer than coarser material and, hence, is more likely to produce a sediment plume.

97. Marine disposal areas are also assessed within **Chapter 16, Infrastructure and Other Users** in relation to accessing the sites.

8.5.2.5. Marine Water and Sediment Contaminants

98. There is little site-specific information on water quality. The offshore area has a dynamic hydrological regime with a varied wave regime and a strong tidal regime that provides the site with high levels of mixing and dispersal. Given the generally low level of industrial activity in adjacent coastal areas and dynamic hydrological regime, it is anticipated that water quality offshore will be good.

99. Sources of sediment input to the coastal area are generally low, although periods of heavy rain increase surface run-off from rural and populated land, increasing riverine and coastal suspended sediment levels. However, sources of contaminated sediment are limited and no sources that would cause significant sediment contamination have been identified.

100. Sediment grain size is a significant factor that controls the capacity for both suspended and bed sediment to concentrate and retain metals and organic pollutants (Horoitz, 1991). Finer sediment fractions (clay and silt sized material (<2 μm)) have a greater adsorbing capacity, owing to larger surface area and greater cation exchange capacity. The proportion of fine sediments within the MDZ is low, with mainly coarse sediments and rock being present due to the presence of strong hydrological regimes. As a result, the sediments surrounding the MDZ are unlikely to contain high concentrations of contaminants.

101. Horizon Nuclear Power (undated) present the results of a water quality survey carried out within the Holyhead North sediment disposal site, approximately 4 km offshore from the WFD designated Caernarfon Bay North coastal water body. This is currently achieving ‘good’ ecological and chemical status under the WFD, while the classified bathing waters on the west coast of Anglesey are all currently rated as achieving excellent status.

102. Horizon Nuclear Power (undated) indicate that physico-chemical parameters were measured *in situ* throughout the vertical water column, including temperature, conductivity, salinity, dissolved oxygen (DO), pH and oxidation-reduction potential (ORP). The chemical and biochemical determinants monitored were total organic carbon (TOC), dissolved organic carbon (DOC), biological oxygen demand (BOD), total suspended solids (TSS), cations and anions, nutrients, metals, organic compounds and cyanide. There was no exceedance of EQS, all concentrations were in line with ‘good’ chemical status as defined by the WFD, most concentrations were below the analytical laboratory’s Minimum Reportable Value and all values were consistent with other coastal waters that are absent of pollutants.

103. In addition, during the October to December 2016 survey, seabed sediment samples were collected for analysis of chemical contaminants. Five samples were collected within the disposal site and one just outside, to the east. The majority of the samples were coarse, with two being finer slightly muddy gravelly sediment. The results showed that levels of contamination in all the sediment samples were below Cefas AL1.

8.5.3. Study Area Sensitivity

104. The study area has a large physical scale and a high degree of temporal and spatial variance. Whilst conservation designations are present within the study area, the sensitivity of the surrounding offshore marine environment with respect to water quality is considered to be Low. However, the landfall and near shore element of the cable route is located close to designated bathing water sites and therefore the sensitivity of the water for the landfall area is considered to be High.

8.6. IMPACT ASSESSMENT

8.6.1. Overview of Potential Impacts

105. The potential impacts on marine water and sediment quality receptors are:

- Changes in marine water quality as a result of sediment re-suspension caused by seabed disturbance;
- Change in marine water quality as a result of mobilisation of contaminants adsorbed onto potentially re-suspended seabed sediments; and
- Impacts on marine water quality and sediment quality as a result of potential accidental discharge and spillage of oils, fuels and materials utilised during construction, operation and decommissioning phases of the Project.

8.6.2. Mitigation Measures

8.6.2.1. Embedded Mitigation

106. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the Project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process.

107. A range of different information sources has been considered as part of embedding mitigation into the design of the Project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

108. The embedded mitigation relevant to marine water and sediment quality includes;

- So far as other constraints (for example, Chapter 24, Chapter Seascape, Landscape and Visual Impact Assessment) allow, devices within the MDZ are most likely to be placed towards the eastern part of the MDZ, where the baseline tidal currents are higher. This means that any suspended sediment effects will be more rapidly and more widely dispersed than if devices were to be placed towards the west of the MDZ.

8.6.2.2. Additional Mitigation Measures

109. An outline Pollution Prevention and Management Plan (**Document MOR/RHDHV/DOC/0077**) and outline Construction Environmental Management Plan (CEMP) (**Document MOR/RHDHV/DOC/0073**) have been prepared to provide an outline of the mitigation measures to be undertaken during construction, to minimise any impacts predicted. will be submitted with the TWAO application and Marine Licence application.

110. The development of the detailed design and final CEMP will refine the worst-case impacts assessed in this EIA. It is recognised that mitigation is an important element in the management and verification of the actual Project impacts. The requirement for appropriate design and scope of mitigation would be agreed with NRW prior to construction works commencing.

8.6.3. Worst Case Scenarios in Relation to Marine Water and Sediment Quality

111. In relation to the marine water and sediment quality within the MDZ and ECC, the worst case would relate to those scenarios which have the greatest potential to disturb seabed sediment. This would cause an increased suspended sediment concentration and could, in turn, lead to increased levels of contaminants within the water column, if contaminants exist in the seabed sediments.

112. With respect to foundation installation, the worst-case option would be pin-piles, as drill arisings (maximum of 117,780 m^3 predicted) and larger sediment plumes are produced during installation of this foundation type compared to Gravity Base Structure (GBS) foundations.

113. In addition, activities with the greatest risk of causing accidental spills/leaks of chemicals and other construction materials are also considered to represent the worst-case scenario. These scenarios are associated with the installation method and type of foundations as well as the installation methods chosen for the inter-array cables and subsea export cable.

114. For the purpose of defining impact assessment parameters for the repowering phase, an assumption has been made that 50 % of the tenants will undertake repowering, i.e. for 50 % of the tenants, their infrastructure will be removed and replaced (potentially with different infrastructure by a different tenant). For the other 50 % of tenants, their infrastructure will remain over the lifetime of the project.

115. In terms of impact assessment parameters, the repowering process has been defined as per below:

- Initial temporary seabed disturbance via deployment of barge anchors to remove foundations, TEC's, hubs, inter-array cables and monitoring equipment for 50 % of the Tenants (berths); and

- Further temporary seabed disturbance via re-installation (repowering) of foundations, TEC's, hubs, inter-array cables and monitoring equipment for the same 50 % of Tenants (berths).

116. The operational phase values include the temporary seabed disturbance that would arise via repowering and also up to ten cable repair events.

117. During all project phases, disturbance to sediments (temporary seabed disturbance) will occur via device, hubs and cable installation and also anchor deployments for installation barges. Based on information provided in **Chapter 4, Project Description**, the values in

118. **Table 8-16** have been calculated to define the worst-case parameters for temporary seabed disturbance. These are defined in terms of project phase, as different amounts of temporary seabed disturbance are predicted to arise in each phase.

Table 8-16 Summary of Worst-Case Scenario Temporary Habitat Loss during Construction, Operation (Repowering) and Decommissioning Phases

Activity	Footprint	Unit	Description of Activity
Construction Phase:			
Post-lay burial of cable	27,259	m^2	Area of sandwave field where post-lay burial via Mass-Flow Excavator (MFE) may be required.
Deployment of anchor blocks by barges during cable installation	100,240	m^2	Up to 8 x 25 m^2 (5x5 m) anchor blocks for a single barge = a total footprint per anchor deployment of 200 m^2 (8 x 25 m^2) Assumed that these types of anchor barges generally deploy a spread every 500 m. So, for every 500 m of cable installation a footprint of 200 m^2 of temporary seabed disturbance occurs (via the anchor blocks) Combining all potential export, array and cable tails the total length of cables (full 240 MW) is 250.6 km Assumes the footprint of 200 m^2 every 500 m (0.5 km), or 400 m^2 every 1 km, and assumes all cables are installed using anchor barges Temporary disturbance impact of (400 m^2 x 250.6) = 100,240 m^2 (0.10 km^2)
Deployment of anchor blocks by barges during TEC device installation	248,000	m^2	Max. no of devices set at 620 x small (0.3 kW devices) Assumed that deployment of each device requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2) Therefore, total temporary seabed disturbance = 620 x 400 m^2 = 248,000 m^2
Deployment of anchor blocks by barges during hub installation	48,000	m^2	Max. no of seabed mounted hubs set at = 120 Assumed that deployment of each hub requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2)

Activity	Footprint	Unit	Description of Activity
			Therefore, total temporary seabed disturbance = 120 x 400 m^2 = 48,000 m^2
Construction Phase TOTAL		**423,499 m^2 (0.42 km^2)**	
Operational Phase:			
50 % of tenants infrastructure (Foundations; TEC's; hubs' array cables; monitoring equipment) removed and replaced with new (different) tenant infrastructure	377,400 m^2	m^2	Initial removal of tenant infrastructure from 50 % of berths ▪ 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 ▪ 50 % of anchor block value of tidal device installation = 124,000 m^2 ▪ 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2 Subsequent re-installation (re-powering) of tenant infrastructure from 50 % of berths ▪ 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 ▪ 50 % of anchor block value of tidal device installation = 124,000 m^2 ▪ 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2
Cable repairs	3,000	m^2	Up to 10 major cable repairs (5 days each) may be required throughout the Project life. It is assumed that up to 750 m of cable will be subject to repair works per event (7,500 m in total). Using same value of 400 m^2 temporary seabed disturbance per 1 km of cable works (400 x 7.5) = 3,000 m^2
Operational Phase TOTAL		**380,400 m^2 (0.38 km^2)**	
Decommissioning Phase:			
Decommissioning Phase TOTAL		**423,499 m^2 (0.42 km^2) –** same worst-case as per construction phase due to same activities needed to remove infrastructure	

119. In addition to these worst-case parameter values for sediment disturbance, there is also the potential for the deterioration in water and sediment quality due to accidental spillages / leakages of construction and maintenance materials as well as fuels and oils from vessels and the tidal devices. It is estimated that there will be approximately 7,000 vessel days throughout the duration of the construction phase; therefore, this number of vessel movements will be taken forward as the worst case scenario.

120. With respect to the liquid inventory of actual devices deployed within the MDZ, the following worst-case values have been assumed:

- Oil (gearboxes, transformers etc.) 240,000 litres;

- Grease (bearing, seals etc.) 12,000 litres; and
- Hydraulic fluid 192,000 litres.

8.6.4. Potential Impacts during Construction

8.6.4.1. Construction Impact 1: Change in Water Quality Due to Sediment Plume Generated via Foundation Installation

121. During the construction phase there is the potential for disturbance and re-suspension of sediments, either directly from the sea bed, or from sub-seabed cuttings, and for these re-suspended sediments to be dispersed through the water column as a plume. This has the potential to increase the baseline suspended sediment concentrations and potentially increase turbidity around the MDZ.

122. During the drilling of pin pile foundations within the proposed MDZ development site, sediments will be released at the surface via the drilling equipment as cuttings of the bedrock which exists below the seabed. In addition, seawater and bentonite are likely to be used as a drilling fluid to lubricate the drill bit and the bentonite will be discharged along with the cuttings. Sediment generated as a result of the installation activities will be finer than the surface sediments. Data from Horizon Nuclear Power and Minesto show that the tidal currents within the MDZ are strong, while SEACAMS modelling shows that the bed shear stresses within the MDZ are sufficiently strong to transport fine and medium sands, and the MDZ is, therefore, dispersive of fine sediments and sands, generally transporting them to the northeast. The fine sediment arising from the pin pile installation activities is therefore likely to be dispersed quickly due to the surrounding energetic tidal environment; with any larger sediment clasts settling in the vicinity of the foundations. Further detail of the results of the coastal modelling conducted in relation to the Project are presented in **Chapter 7, Metocean Conditions and Coastal Processes**.

123. Based on a 240 MW capacity, the worst-case volume of cuttings for the entire site would amount to 117,780 m^3. However, this is the total for all foundations and foundations will be installed sequentially. A single device requiring four drilled piles will produce 160 m^3 of cuttings.

124. As discussed in **Chapter 7, Metocean Conditions and Coastal Processes**, this is likely to result in peak increases in suspended sediment concentration at the points of release within the Project being only a few mg/l (typically less than 10 mg/l) and peak values at only a short distance from each release point reducing rapidly to less than 1 mg/l. This low (barely measurable) effect is partly due to the low volume of sediment released from drilling at the location of each release point, and partly because any fine material released would be rapidly dispersed by the strong tidal currents along the axis of tidal flow.

125. The maximum envisaged effect associated with sediment plumes arising from the foundation installation activities will cause a small increase in suspended sediment concentration (typically less than 1 mg/l a short distance from the release point) over only a small geographical area (a few hundred metres). The effects will be temporary, with a return to very low background concentrations occurring rapidly upon cessation of installation activities (i.e. the effect is temporary only). Other than at the immediate release point, such a change would be immeasurable.

126. Therefore, the negligible magnitude of effect coupled with the low sensitivity of water quality receptors in this area result in a **negligible** impact via increased suspended sediment via foundation installation.

8.6.4.1.1. Mitigation

127. None required.

8.6.4.1.2. Residual Impact

128. The residual impact on water quality via sediment plume generated during foundation installation will remain **negligible**.

8.6.4.2. Construction Impact 2: Change in Water Quality Due to Sediment Plume Generated via Cable Installation

129. During the construction phase there is potential for offshore cable installation activities within the cable corridor (including the nearshore and landfall) to disturb sediments and release them into the water column as a plume. This will enhance the baseline suspended sediment concentrations in the water column, making it more turbid, until the plume becomes dispersed by tidal current action and the sediments settle once again on the sea bed.

130. The offshore parts of the cable corridor are mostly covered by large areas of outcropping bedrock, with minimal relief and only sparse sediment cover, predominantly gravel, cobbles and rock boulders. However, the northern part of the cable corridor is covered by a sand ridge north of South Stack headland and extending northwest for around 1 km. This is where post-lay jetting may be required to bury the offshore cable, which would cause some sea bed sediment disturbance.

131. Nearer to the landfall, Abraham's Bosom is a bay bounded by rock headlands to the north and south, with a cover of sediment overlying bedrock. The grab sample from this location recovered medium-grained sand. Just offshore of the bay is a patch of megaripples (up to 0.6 m high).

132. The free-laying of cables and the placement of cable protection would not cause plumes along the offshore sections of the cable corridor because the sea bed is characterised by bedrock or, where sparse sediment cover does exist, by sediments with a particle size that cannot be suspended in the water column. In the nearshore, the bedrock is overlain by sand which has the potential to be disturbed by the free-laying of cables and the placement of cable protection. However, any plume arising from these activities would only arise from the force of the cable or protection measures on the sea bed. At the landfall, the worst case scenario would be open trenching rather than the preferred option of Horizontal Directional Drilling (HDD). Under open trenching, approximately 8,880 m^3 of sand would be excavated and the majority replaced to backfill the trench, with only a small net loss to the inshore system. Due to these factors, the likely increase in suspended sediment concentration in areas with sand cover nearer to shore (including at the landfall) will remain within the bounds of natural behaviour that are governed by storm waves and surge effects. Furthermore, these effects will be one-off and temporary in duration and are unlikely to be measurable.

133. The principal effect would arise from the post-installation jetting to bury the offshore cable across the sand ridge feature in the northern half of the cable corridor. Under this activity, it is likely that the maximum envisaged effect associated with sediment plumes arising from the jetting will cause only modest (but measurable) increases in suspended sediment concentration locally (typically a few tens of mg/l above background levels). This increase would reduce rapidly with distance from the point of disturbance to a few mg/l over a small geographical area (within a few hundred metres, along the axis of tidal currents). Furthermore, these effects will be one-off and temporary in duration, with a return to the very low background concentrations occurring rapidly upon cessation of installation.

134. Therefore, the low magnitude of effect coupled with the low sensitivity of water quality receptors in this area result in a **minor adverse** impact via increased suspended sediments in the area around the sandwave field and a lower, **negligible** impact in other areas away from the sandwave field.

8.6.4.2.1. Mitigation

135. None required.

8.6.4.2.2. Residual Impact

136. The residual impact on water quality in the area around the sand-wave field will remain as **minor adverse.** The residual impact on water quality via cable installation in other parts of the MDZ will remain **negligible**.

8.6.4.3. Construction Impact 3: Change in Water Quality Due to Release of Contaminated Sediments

137. The re-suspension of sediments during construction activities could also lead to the release of any contaminants that may be present within them, which may in turn affect compliance with water quality standards.

138. The baseline environment section concluded that sediment contamination within the MDZ is low, due to the dynamic hydrological regime and generally low level of industrial activity in this region. The low proportion of fine sediments within the MDZ (which have a greater adsorbing capacity for contaminants) is another factor that indicates low sediment contamination levels.

139. Therefore, even though mobilisation of the relatively limited amount of sediments in the MDZ will occur via construction works, none of these sediments are known to have high levels of contaminants, which will result in a negligible magnitude of effect. The sensitivity of receptors in this area to water quality changes is low, therefore a **negligible** impact is predicted on general water quality in the MDZ via release of contaminated sediments.

8.6.4.3.1. Mitigation

140. None required.

8.6.4.3.2. Residual Impact

141. The residual impact on water quality via potential release of contaminated sediments in the MDZ will remain **negligible**.

8.6.4.4. Construction Impact 4: Change in Water Quality Due to Discharge of Construction Material and/or Chemicals

142. The liquid inventory for the Project indicates that there are large amounts of chemicals including oil, grease and hydraulic fluid that could be accidentally released/leaked from Project components. Other sources of potential chemicals include drilling fluids from any drilled pin-piles and also from HDD works at landfall.

143. If any such substances were accidentally released/leaked, quantities would likely be small due to relatively small amounts being present in individual devices. Due to the dynamic nature of the tidal and wave regime in and around the MDZ, lateral and vertical dispersion rates of any spilled substances would be expected to be high. The magnitude of this potential effect is considered to be low, as it is not anticipated to significantly affect local water quality and would also be temporary in nature (established controls would prevent further spillage/leakage once an event was detected).

144. The receptor is defined as general water quality and is judged to be low. Therefore, a **minor adverse** impact on general water quality in and around the MDZ is predicted.

8.6.4.4.1. Mitigation

145. Adherence to a project-specific Construction Environmental Management Plan (CEMP) and Pollution Prevention and Management Plan (PPMP). All solids will be separated from the drill fluid and disposed of in accordance with a project-specific Site Waste Management Plan; this is expected to stipulate the offsite removal of solids from drill arisings. Bentonite clay and water are considered to be non-toxic earthen materials and any arisings are likely to be dispersed quickly due to the dynamic tidal environment.

146. Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. A Pollution Prevention Management Plan (PPMP) would be in place and agreed with NRW in line with the Integrated Pollution Prevention and Control (IPPC) Directive such that any potential risk is minimised. Any permitted discharges would be small volumes, intermittent and dilute and disperse quickly. An outline Pollution Prevention and Management Plan (**Document MOR/RHDHV/DOC/0077**) and outline Construction Environmental Management Plan (CEMP) (**Document MOR/RHDHV/DOC/0073**) has also been prepared to provide an outline of the mitigation measures to be undertaken during construction, to minimise any impacts predicted.

8.6.4.4.2. Residual Impact

147. The residual impact on local water quality via potential release of construction materials and/or chemicals is judged to be reduced to **negligible** if appropriate mitigation measures are adhered to.

8.6.4.1. Construction Impact 5: Deterioration in Status of WFD Waterbodies and/or Local Designated Bathing Waters

148. The existing environment section indicated the MDZ lies in close proximity to two Welsh WFD Coastal Water Bodies – the eastern part of the MDZ overlaps the Caernarfon Bay North (GB621010380000) water body, while the Holyhead Bay (GB681010360000) is located approximately 3 km away from the MDZ at its nearest point (**Figure 8-1, Volume II**).

149. There are also six designated bathing water beaches along the west coast of Anglesey all of which meet the higher water quality standard and have consistently met the higher standard since 2010.

150. Potential exists for the status of these waterbodies/beaches to be adversely affected via deterioration in water quality/release of contaminants due to construction activities. However, the preceding impact assessments have concluded that no significant impacts on water quality are predicted via planned works. Therefore, it is judged that the magnitude of any effect is low.

151. The sensitivity of these receptors is judged to be medium as they have formal EU-level designations that require regular monitoring and compliance with. Therefore, a **minor adverse** impact is predicted on local WFD waterbodies and designated beaches via deteriorations in water quality during construction.

8.6.4.1.1. Mitigation

152. Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations.

8.6.4.1.2. Residual Impact

153. The residual impact on these WFD waterbody and bathing beach receptors via potential release of construction materials and/or chemicals is judged to be reduced to **negligible** if appropriate mitigation measures are adhered to.

8.6.5. Potential Impacts during Operation

8.6.5.1. Operational Impact 1: Change in Water and/or Sediment Quality Due to Accidental Spillages/Leaks from Operational Devices

154. During the operational phase of the Project there is a potential risk to water and/or sediment quality via accidental spillage or release of materials such as grease and oils during maintenance work and from vessels associated with these works. Similar scope for accidental spillages/leaks will arise during any major cable repair works and/or repowering activities.

155. Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. An PPMP would be in place and agreed with NRW in line with the IPPC Directive such that any potential risk is minimised. Any permitted discharges would be small volumes, intermittent and dilute and disperse quickly.

156. As per during the construction phase, if any such substances were accidentally released/leaked, quantities would likely be small due to relatively small amounts being present in individual devices. Due to the dynamic nature of the tidal and wave regime in and around the MDZ, lateral and vertical dispersion rates of any spilled substances would be expected to be high. The magnitude of this potential effect is considered to be low, as it is not anticipated to significantly affect local water quality and would also be temporary in nature (established controls would prevent further spillage/leakage once an event was detected).

157. The receptor is defined as general water quality and is judged to be medium. Therefore, a minor adverse impact on general water quality in and around the MDZ is predicted.

8.6.5.1.1. Mitigation

158. Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations.

8.6.5.1.2. Residual Impact

159. The residual impact on local water/sediment quality via potential leaks/releases of chemicals and other substances from operational devices and/or operation and maintenance activities is judged to be reduced to **negligible** if appropriate mitigation measures are adhered to.

8.6.5.2. Operational Impact 2: Change in Water Sediment Quality Due to Sediment Plumes Generated by Repowering and/or Cable Repair Works

160. During the operational phase of the Project there is an assumption that repowering of a maximum of 50 % of the berths will occur. In the 50 % of berths affected, all tenant infrastructure (foundations; TEC's; hubs; array cables will be removed and then new (possibly different) infrastructure will be re-installed (repowered). This will result in two, temporally separate effects of temporary seabed disturbance via the deployment of barge anchors to firstly remove infrastructure and then, further barge anchor deployments to re-install new infrastructure.

161. An assumption has been made that cable repairs would be required in the operational phase, with further temporary seabed disturbance from barge anchors deployed to undertake these repair operations.

162. The quantification of these potential impact (as defined by footprint of temporary seabed disturbance) is set out in **Table 8-15**.

163. These activities will create similar effects as previously assessed for the construction phase. The potential removal and re-installation of seabed mounted devices and/or seabed anchor systems for floating devices coupled with potential cable de-burial and re-burial in sedimentary areas will all result in creation of localised sediment plumes and subsequent deposition.

164. The magnitude of this effect will be less than for the main construction phase (0.42 km^2) due to a lower amount of temporary seabed disturbance via these operational phase activities (0.38 km^2). Therefore, magnitude is assessed as negligible.

165. The sensitivity of water quality receptors is judged to remain as low, resulting in a **negligible** impact.

8.6.5.2.1. Mitigation

166. None required.

8.6.5.2.2. Residual Impact

167. Negligible.

8.6.5.3. Operational Impact 3: Change in Water Sediment Quality Due to Sediment Plumes Produced via Scour around Seabed Mounted Project Infrastructure

168. Placing any structure on the seabed has the potential to result in scour around the structure, leading in turn to mobilisation of any available sediment in the area around the structure via plumes.

169. In areas of the MDZ where the sea bed is comprised of bare bedrock or where this is covered with boulders, cobbles or gravels there is unlikely to be any scouring effects, therefore there will be no change in suspended sediment concentrations. Where devices are placed in areas of the MDZ characterised by sands (e.g. southwest section and in the vicinity of the sand ridge in the north) there is potential for locally accelerated flows around foundations to increase suspended sediment concentrations, but since flows in these areas are very high in the baseline conditions, this will not be a major exacerbation of the issue.

170. Given the nature of the sea bed morphology, comprised mostly of exposed bedrock, the potential for adverse effects of this nature is extremely limited.

171. Therefore, for the majority of the site, where sediment cover is absent/limited, the magnitude of this effect is judged to be negligible. Coupled with the low sensitivity of water quality receptors, a negligible impact is predicted.

172. In areas where there is some sediment cover and, thus where scour may occur, the magnitude of effect is judged to be low. Coupled with the low sensitivity of water quality receptors in this area this results in a minor adverse impact.

8.6.5.3.1. Mitigation

173. There is no recommended further mitigation.

8.6.5.3.2. Residual Impact

174. The residual impact on water quality via scour-induced plumes in the area around the sand-wave field will remain as **minor**. The residual impact on water quality via scour-induced plumes in all in other parts of the MDZ will remain **negligible**.

8.6.6. Potential Impacts during Decommissioning

8.6.6.1. Decommissioning Impact 1: Changes in Suspended Sediment Concentrations During Removal of Project Infrastructure

175. During the decommissioning phase the removal of Project infrastructure has the potential to disturb sediments on the sea bed and release them into the water column as a plume. If this effect does occur, the magnitude of the effect will generally be lower than the effects arising from installation of foundations/cables.

176. The magnitude of effect is judged to be low and receptor sensitivity low, resulting in a **negligible impact.**

8.6.6.1.1. Mitigation

177. There is no recommended further mitigation.

8.6.6.1.2. Residual impact

178. The residual impact on water quality via plumes created via decommissioning activities will remain **negligible.**

8.6.6.2. Decommissioning Impact 2: Change in Water and/or Sediment Quality due to Accidental Spillages/Leaks from Vessels Involved in Decommissioning Works

179. During the decommissioning phase of the Project there is a potential risk to water and/or sediment quality via accidental spillage or release of materials from vessels associated with the works. Similar scope for accidental spillages/leaks will arise during any major cable repair works and/or repowering activities.

180. As per during the construction phase, if any such substances were accidentally spilt/leaked, quantities would likely be small due to relatively small amounts being present in individual devices. Due to the dynamic nature of the tidal and wave regime in and around the MDZ, lateral and vertical dispersion rates of any spilled substances would be expected to be high.

181. The magnitude of this potential effect is considered to be low, as it is not anticipated to significantly affect local water quality and would also be temporary in nature (established controls would prevent further spillage/leakage once an event was detected.

182. The receptor is defined as general water quality and is judged to be low. Therefore, a minor adverse impact on general water quality in and around the MDZ is predicted.

8.6.6.2.1. Mitigation

183. As per for the construction and operational phase impacts, Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. A PPMP would be in place and agreed with NRW in line with the IPPC Directive such that any potential risk is minimised.

184. Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance.

8.6.6.2.2. Residual Impact

185. The residual impact on local water/sediment quality via potential leaks/releases of chemicals and other substances from devices being decommissioned and/or vessels involved in these works is judged to be reduced to **negligible** if appropriate mitigation measures are adhered to.

8.6.7. Cumulative Impacts

186. Of the projects listed in **Chapter 27, Cumulative and In-combination Effects**, the only one which could potentially have a cumulative or in-combination effect with the Project in respect of marine water and sediment quality is judged to be Minesto's Holyhead Deep project, which lies immediately to the west of the MDZ. All other projects listed are either too remote from the Project for interactions between water/sediment quality impacts or on land and thus do not affect coastal processes.

187. In June 2014, Minesto was awarded an Agreement for Lease by The Crown Estate for a 10 MW installation, the Holyhead Deep project. An initial deployment of a 0.5 MW device was undertaken in summer 2018.

188. Minesto are now beginning EIA studies for a planned 80 MW installation of tidal energy devices, delivered in a phased manner, and located a short distance due west of the MDZ Project. Based upon the geographical configuration of the Minesto Project Development Area (PDA) with respect to the MDZ Project, there is no possibility of changes in tidal flow interacting between projects, due to the alignment of flood and ebb flows off the coast of Anglesey (i.e. the two projects are not upstream/downstream of each other).

189. Similarly, any (minor) sediment plumes arising from construction from either project will not coalesce because of: (i) the alignment of principal tidal flows; and (ii) likely different construction programmes (note that phase 1 of the Holyhead Deep project is already installed).

190. The one area where potential cumulative impact may occur were if construction activities were to occur simultaneously on both projects, which could produce a cumulative impact via spill events and accidental discharges of liquids/materials. If this cumulative impact occurred, a major adverse impact on local marine water quality could be produced. However, both projects would independently adopt standard best practice measures with respect to spill prevention and response and as such, the significance of this potential cumulative impact would be reduced to a negligible level.

8.6.8. Inter-Relationships

191. **Table 8-17** lists out the inter-relationships between this chapter and other chapters within the ES.

Table 8-17 Inter-Topic Relationships

Topic and description	Related Chapter	Where addressed in this Chapter	Rationale
Metocean Conditions and Coastal Processes	Chapter 7	Section 8.5.2 and 8.6.4	Both chapters consider the potential effects of the Project on suspended sediment concentrations
Infrastructure and Other Users	Chapter 16	Section 8.5.2	Both chapters consider the potential effects of disposal sites on the Project

192. Habitat loss and disturbance is also discussed separately in a number of other chapters, including **Chapter 9, Benthic and Intertidal Ecology** and **Chapter 10, Fish and Shellfish Ecology**.

8.6.9. Interactions

193. The impacts identified and assessed in this chapter have the potential to interact with each other, which could give rise to synergistic impacts as a result of that interaction. The worst case impacts assessed within the chapter take these interactions into account and for the impact assessments are considered conservative and robust. For clarity the areas of interaction between impacts are presented in **Table 8-18**, along with an indication as to whether the interaction may give rise to synergistic impacts.

Table 8-18 Potential Interaction Between Impacts

Potential interaction between impacts					
Construction	1. Change in water quality via foundation installation	2. Change in water quality via cable installation	3. Change in water quality due to release of contaminated sediments	4. Change in water quality due to discharge of construction material and/or chemicals	5. Deterioration in status of WFD waterbodies etc.
1. Change in water quality via foundation installation	-	Yes	No	Yes	No
2. Change in water quality via cable installation	Yes	-	No	Yes	No
3. Change in water quality due to release of contaminated sediments	No	No	-	No	No
4. Change in water quality due to discharge of construction material and/or chemicals	Yes	Yes	No	-	Yes
5. Deterioration in status of WFD waterbodies and/or local designated bathing waters	No	No	No	Yes	-

Potential interaction between impacts			
Operation / Repowering	1. Change in water and/or sediment quality due to accidental spillages/leaks	2. Change in water sediment quality due to sediment plumes	3. Change in water sediment quality due to sediment plumes produced via scour
1. Change in water and/or sediment quality due to accidental spillages/leaks from operational devices	**-**	Yes	Yes
2. Change in water sediment quality due to sediment plumes generated by repowering and/or cable repair works	Yes	**-**	Yes
3. Change in water sediment quality due to sediment plumes produced via scour around seabed mounted Project infrastructure	Yes	Yes	-
Decommissioning	1. Changes in suspended sediment concentrations	Change in water and/or sediment quality	
1. Changes in suspended sediment concentrations during removal of Project infrastructure	**-**	Yes	
2. Change in water and/or sediment quality due to accidental spillages/leaks from vessels involved in decommissioning works	Yes	-	

8.7. SUMMARY

194. This chapter has provided an overview on the potential impacts which may occur within the several stages associated with the development of the Project: construction, operation, repowering and maintenance, and decommissioning to marine and water sediment quality within the MDZ.

195. **Table 8-19** collates the determinations of each of the impacts assessed and is presented as a summary of the determinations. It is evident that the vast majority of the impacts to the Marine Water and Sediment Quality throughout the various stages of development are likely to be of minor adverse significance, even when assessed with the worse-case scenario. Therefore, the effects on the Marine Water and Sediment Quality are unlikely to cause long-term changes to the MDZ environment and surrounding region, either through direct changes in the species composition or due to changes in sediment structure.

Table 8-19 Summary of Potential Impacts on Marine Water and Sediment Quality Associated with the Development of the Project

Potential Impact	Effect Magnitude	Receptor Sensitivity	Significance	Additional Mitigation Measures	Residual Impact
Construction Phase					
1. Change in water quality due to sediment plume generated via foundation installation	Negligible	Low	Negligible	None required	Negligible
2. Change in water quality due to sediment plume generated via cable installation	Low (sandwave area) Negligible (other areas)	Low	Minor Adverse (sandwave area) Negligible (other areas)	None required	Negligible
3. Change in water quality due to release of contaminated sediments	Negligible	Low	Negligible	None required	Negligible
4. Change in water quality due to discharge of construction material and/or chemicals	Low	Low	Minor Adverse	Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations	Negligible
5. Deterioration in status of WFD waterbodies and/or local designated bathing waters	Low	Medium	Minor Adverse	Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations	Negligible
Operational / Repowering Phase					
1. Change in water and/or sediment quality due to accidental spillages/leaks from operational devices	Low	Low	Negligible	Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations.	Negligible

Potential Impact	Effect Magnitude	Receptor Sensitivity	Significance	Additional Mitigation Measures	Residual Impact
2. Change in water sediment quality due to sediment plumes generated by repowering and/or cable repair works	Negligible	Low	Negligible	None required	Negligible
3. Change in water sediment quality due to sediment plumes produced via scour around seabed mounted Project infrastructure	Low (sandwave/ sediment areas) Negligible (no sediment areas)	Low	Minor	None required	Minor adverse (sandwave / sediment areas) Negligible (no sediment areas)
Decommissioning Phase					
1. Changes in suspended sediment concentrations during removal of Project infrastructure	Negligible	Low	Negligible	None required	Negligible
2. Change in water and/or sediment quality due to accidental spillages/leaks from vessels involved in decommissioning works	Low	Low	Minor Adverse	Adherence to project-specific CEMP and PPMP which themselves will take full account of relevant pollution control legislation and guidance, i.e. MARPOL regulations.	Negligible

GLOSSARY OF TERMINOLOGY

Anthozoa	A class of marine animals including sea anemones and coral
Ascidian	A marine invertebrate - a sea quirt or tunicate
Bathymetry	Topography of the sea bed
Benthic	The lowest level of a body of water including the sediment surface
Bioaccumulation	The gradual accumulation of substances in an organism
Biogenic	Something that is produced or brought about by living organisms, such as a reef
Biotope	A region of habitat associated with a particular ecological community
Circalittoral	The region of a sea or ocean below the infralittoral zone to the maximum depth at which photosynthesis is still possible
Current	Flow of water generated by a variety of forcing mechanisms (e.g. waves, tides, wind)
Ebb tide	The falling tide, immediately following the period of high water and preceding the period of low water
Ecology	The relation of organisms to one another, and to their physical surroundings
Eulittoral	The area of the shore between the spring high and spring low tide lines.
Fetch	The distance travelled by wind or waves across open water
Flood tide	The rising tide, immediately following the period of low water and preceding the period of high water
Gravel	Loose, rounded fragments of rock larger than sand but smaller than cobbles. Sediment larger than 2mm (as classified by the Wentworth scale used in sedimentology)
Habitat	The environment of an organism and the place where it is usually found
Infralittoral	The region of shallow water closest to the shore, excluding the intertidal, dominated by algae
Intertidal	Area on a shore that lies between Lowest Astronomical Tide (LAT) and Highest Astronomical Tide (HAT)
Littoral	The area of a sea or lake between the high water mark and the edge of the continental shelf

Megaripples	Bedforms with a wavelength of 0.6 to 10.0m and a height of 0.1 to 1.0m. These features are smaller than sand waves but larger than ripples
Numerical modelling	Refers to the analysis of coastal processes using computational models
Offshore	Area to seaward of nearshore in which the transport of sediment is not caused by wave activity
Polychaete	A marine worm, such as a bristle worm
Sand	Sediment particles, mainly of quartz with a diameter of between 0.063mm and 2mm. Sand is generally classified as fine, medium or coarse
Scour	The erosion of sediment away from tan area as a result of the flow of water.
Sediment	Particulate matter derived from rock, minerals or bioclastic matter
Sediment transport	The movement of a mass of sediment by the forces of currents and waves
Shallow water	Commonly, water of such depth that surface waves are noticeably affected by bottom topography. It is customary to consider water of depths less than half the surface wave length as shallow water
Spring tide	A tide that occurs when the tide-generating forces of the sun and moon are acting in the same directions, so the tidal range is higher than average
Sublittoral	The area of a sea or ocean where sunlight reaches the sea floor, includes the infra- and circalittoral zones
Substrate	The surface or material on or from which an organism lives, grows, or obtains its nourishment.
Subtidal	An area of sea bed which lies below the level of the Lowest Astronomical Tide
Supralittoral	The area above the spring high tide line that is regularly splashed, but not submerged by ocean water
Surge	Changes in water level as a result of meteorological forcing (wind, high or low barometric pressure) causing a difference between the recorded water level and the astronomical tide predicted using harmonic analysis
Suspended sediment	The sediment moving in suspension in a fluid kept up by the upward components of the turbulent currents or by the colloidal suspension
Tidal current	The alternating horizontal movement of water associated with the rise and fall of the tide
Tide	The periodic rise and fall of the water that results from the gravitational attraction of the moon and sun acting upon the rotating earth

9. BENTHIC AND INTERTIDAL ECOLOGY

9.1. INTRODUCTION

1. Menter Môn Morlais Limited (Menter Môn) proposes the development of 240 MW of tidal generating capacity within the Morlais Demonstration Zone (MDZ). The development of the Morlais Project (the Project) will support the development of renewable energy technology objectives of the Anglesey and Gwynedd Joint Local Development Plan (JLDP), providing a consented tidal technology commercial demonstration zone which supports installation, testing and commercial demonstrations of tidal energy devices. The Project will also provide opportunities for the local communities via direct employment and support of the local supply chain.

2. The Project will include communal infrastructure for tidal technology developers which provides a shared route to a local grid connection via nine export cable tails, an onshore landfall substation, and an onshore electrical cable route to a grid connection via a grid connection substation.

3. This chapter provides a summary description of key aspects relating to existing benthic and intertidal ecology, followed by an assessment of the magnitude and significance of the effects on the baseline conditions resulting from the construction, operation and decommissioning of the Project, as well as those effects resulting from cumulative interactions with other existing or planned projects.

4. This chapter incorporates the data collected from the 2018 subtidal and intertidal surveys conducted by Ocean Ecology Ltd (OEL) (Ocean Ecology, 2018) within the MDZ and surrounding environment. The assessment process has been informed by the following:

   - **Chapter 7, Metocean Conditions and Coastal Processes**;
   - Interpretation of survey data specifically collected for the project including intertidal survey, benthic survey and analysis of seabed sediments;
   - Consideration of the existing evidence base regarding the effects of Project infrastructure on the subtidal and intertidal environments; and
   - Application of expert-based assessment and judgement by MarineSpace Ltd.

5. This chapter has been prepared by MarineSpace Ltd on behalf of Menter Môn

9.2. POLICY, LEGISLATION AND GUIDANCE

6. This section outlines the relevant national and regional policy and guidance and industry guidance which has be used to support the compilation of this Chapter.

7. An overview of the relevant legislative context for the Project is provided in **Chapter 2, Policy and Legislation**.

8. In addition to the general legislation and policy guidance set out in **Chapter 2, Policy and Legislation**, industry guidance on the generic requirements for the assessment of impacts on

benthic ecology studies associated with tidal array developments is provided by Natural Resources Wales (NRW) (Guidance Note 030) (NRW, 2018):

International:

- Habitats Directive Council (Directive 92/43/EEC) and other associated habitat regulations:
  - Birds Directive (Directive 2009/147/EC);
  - Ramsar Convention of Wetlands of International Importance;
  - Water Framework Directive (WFD) (EU Directive 200/60/EC);
  - Marine Strategy Framework Directive (MSFD); and
  - The Convention for the Protection of the Marine Environment of the North-East Atlantic (the OSPAR Convention 1992).

National:

- Environment (Wales) Act 2016;
- The Wildlife and Countryside Act 1981(amended by the Countryside and Rights of Way (CROW) Act 2000);
- Marine and Coastal Access Act;
- Welsh Marine Protected Area Network; and
- Draft Wales National Marine Plan (WNMP).

Regional:

- Anglesey and Gwynedd Joint Local Development Plan (JLDP).

9.2.1. National Policy Statements

9. The Project is seeking consent for a Transport and Works Act Order from the Welsh Government and a Marine Licence from Natural Resources Wales (NRW). Although this project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts on marine water and sediment quality for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to marine water and sediment quality include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011a); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011 (DECC, 2011b).

10. Details of specific policies within EN-1 and EN-3 used to inform this assessment are provided in **Table 9-1** below. The specific assessment requirements for marine water and sediment quality are detailed, together with an indication of the paragraph numbers of the chapter where each is addressed.

Table 9-1 NPS EN-1 and EN-3 Assessment Requirements Relevant to Marine Water and Sediment Quality

NPS Requirement	NPS Reference	ES Reference
Where the development is subject to EIA the applicant should ensure that the ES clearly sets out any effects on internationally, nationally and locally designated sites of ecological or geological conservation importance, on protected species and on habitats and other species identified as being of principal importance for the conservation of biodiversity. The applicant should provide environmental information proportionate to the infrastructure where EIA is not required to help the IPC consider thoroughly the potential effects of a proposed project.	EN-1 Section 5.3.3	The designated sites relevant to the assessment are outlined in **Section 9.5.6**.
Applicants should assess the potential for the scheme to have both positive and negative effects on marine ecology and biodiversity.	EN-3 Para 2.6.67	Potential impacts of the Project on benthic and marine ecology are presented in **Section 9.6**.
Mitigation may be possible in the form of a careful design of the development itself and the construction techniques employed.	EN-3 Para 2.6.70	Embedded and additional mitigation measures are outlined in **Section 9.6.1**.
An assessment of the effects of installing cable across the intertidal zone should include information, where relevant, about: ▪ Any alternative landfall sites that have been considered by the applicant during the design phase and an explanation for the final choice; ▪ Any alternative cable installation methods that have been considered by the applicant during the design phase and an explanation for the final choice; ▪ Potential loss of habitat; ▪ Disturbance during cable installation and removal (decommissioning); ▪ Increased suspended sediment loads in the intertidal zone during installation; and ▪ Predicted rates at which the intertidal zone might recover from temporary effects.	EN-3 Para 2.6.81	The Project will use Horizontal Directional Drilling as the method of construction at landfall, which will avoid direct impacts to sensitive habitats and species. In case this is not technically feasible the worst case assessment covers trenching and/or surface laying of cables. Potential impacts of the Project on benthic and marine ecology are presented in **Section 9.6**. Potential impacts of the Project on ecology at the landfall, above Mean High Water, are presented in **Chapter 19, Onshore Ecology**
Applicants are expected to have regard to guidance issued in respect of Food and Environmental Protection Act (FEPA) [now Marine Licence] requirements.	EN-3 Section 2.6.83	Other relevant guidance, including in respect to the Marine Licence, is outlined further below in this section.
Where necessary, assessment of the effects on the subtidal environment should include: ▪ Loss of habitat due to foundation type including associated sea bed preparation, predicted scour, scour protection and altered sedimentary processes;	EN-3 Section 2.6.113	Due to the nature of the seabed within the MDZ and ECC, the preferred method of cable installation is surface laying. Potential impacts

NPS Requirement	NPS Reference	ES Reference
▪ Environmental appraisal of array cables and cable routes and installation methods; ▪ Habitat disturbance from construction vessels' extendible legs and anchors; ▪ Increased suspended sediment loads during construction; and ▪ Predicted rates at which the subtidal zone might recover from temporary effects.		of the Project on benthic and marine ecology are presented in **Section 9.6**.
Construction and decommissioning methods should be designed appropriately to minimise effects on subtidal habitats, taking into account other constraints. Mitigation measures which the Infrastructure Planning Commission (IPC) (now the Planning Inspectorate) should expect the applicants to have considered may include: ▪ Surveying and micrositing of the export cable route to avoid adverse effects on sensitive habitat and biogenic reefs; ▪ Burying cables at a sufficient depth, taking into account other constraints, to allow the seabed to recover to its natural state; and ▪ The use of anti-fouling paint might be minimised on subtidal surfaces, to encourage species colonisation on the structures.	EN-3 Section 2.6.119	Potential construction, operation, repowering and decommissioning impacts of the Project on benthic and marine ecology are presented in **Sections 9.6.2, 9.6.3** and **9.6.4.** Details of mitigation measures are provided within each of these sections where necessary.
Activities should have been designed taking into account sensitive benthic environmental aspects and intertidal habitats.	EN-3 Para 2.6.116	Details of the existing environment are provided in Section 9.5 and mitigation measures where necessary are provided in **Sections 9.6.2, 9.6.3** and **9.6.4.**
Where adverse effects are predicted, the assessment should consider the extent to which the effects are temporary or reversible. This includes the installation and decommissioning of cables.	EN-3 Para 2.6.117	The magnitude of each impact, which includes the extent to which the effects are temporary or reversible, has been considered in **Sections 9.6.2, 9.6.3** and **9.6.4.**

9.2.2. Marine Policy Statement

11. The Marine Policy Statement (MPS) adopted by all UK administrations in March 2011 provides the policy framework for the preparation of marine plans and establishes how decisions affecting the marine area should be made in order to enable sustainable development. The MPS sets out a vision of having 'clean, healthy, safe, productive and biologically diverse oceans and seas' by supporting the development of Marine Plans. It also sets out the framework for environmental, social and economic considerations that need to be considered in marine planning.

9.2.3. Wales National Marine Plan

12. By adopting the MPS, the Welsh Government committed to the requirement to introduce Marine Plans for Wales.

13. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the Welsh National Marine Plan (WNMP). The Plan is being developed in accordance with the Marine and Coastal Access Act (MCAA) 2009, the MPS and the Maritime Spatial Planning Directive, a draft version has been issued for consultation (discussed further in **Chapter 2, Policy and Legislation**).

14. Objective 10 of the WNMP, “to maintain and enhance the resilience of marine ecosystems and the benefits they provide in order to meet the needs of present and future generations”, is of relevance to this chapter as this covers policies and commitments on the wider ecosystem, as set out in the MPS including those to do with the Marine Strategy Framework Objective Directive and the Water Framework Directive, as well as other environmental, social and economic considerations.

15. **Table 9-2** sets out other national and regional policies which are particularly relevant to the Project.

Table 9-2 National and Regional Policy Requirements Relevant to Benthic and Intertidal Ecology

Policy Description	Reference	ES Reference
MPS		
Noise resulting from a proposed activity or development in the marine area or in coastal and estuarine waters can have adverse effects on biodiversity although knowledge of the extent of impacts is limited and there are few systematic monitoring programmes to verify adverse effects. Man-made sound emitted within the marine environment can potentially affect marine organisms in various ways. It has the potential to mask biologically relevant signals; it can lead to a variety of behavioural reactions, affect hearing organs and injure or even kill marine life. Manmade sound sources of primary concern with regard to disturbance of marine life are explosions, shipping, seismic surveys, offshore construction and offshore industrial activities, for example dredging, drilling and piling, sonar of various types and acoustic deterrent devices.	Section 2.6.3.1	Indirect noise impacts arising from the Project have been assessed on fish, birds and marine mammals. Please see **Chapters 10**, **Fish and Shellfish Ecology**, **Chapter 11, Marine Ornithology** and **Chapter 12 Marine Mammals**.
The UK Administrations are committed to allowing damaged ecosystems to recover in order to realise the benefits from the marine environment. This will be achieved through integrating conservation objectives into marine planning and decision making and incorporating the requirements for specific designated conservation areas.	Section 3.1.1	Conservation importance and objectives, where applicable are discussed in **Section 9.5.5**. Designated sites are presented in **Section 9.5.6**. Protected habitats and species are discussed in **Section 9.5.7**. These are considered fully within the impact assessment (**Section 9.6**)
These are sites identified and designated under Directives and include Special Areas of Conservation (SACs)	Section 3.13	Designated sites are presented in **Section 9.5.6**.

Policy Description	Reference	ES Reference
designated under the Habitats Directive, and Special Protection Areas (SPAs) classified under the Wild Birds Directive for rare, vulnerable and migratory bird populations. The Conservation of Habitats and Species Regulations 2010, the Conservation (Natural Habitats &c) Regulations 1994 (for Scotland only), the Conservation (Natural Habitats &c) Regulations (Northern Ireland) 1995 and the Offshore Marine Conservation (Natural Habitats &c) Regulations 2007, among others, provide statutory protection for these sites64, but do not provide statutory protection for potential Special Protection Areas (pSPAs) before they have been classified as SPAs. For the purpose of considering development proposals affecting them, as a matter of policy, UK Administrations wish pSPAs to be considered in the same way as if they had already been classified. Listed Ramsar sites also receive the same protection.		These are considered fully within the impact assessment (**Section 9.6**) as well as the Information to Support HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**)
A number of SSSIs extend into the marine environment, primarily the inter-tidal zone. The statutory protection afforded to SSSIs, and the procedures to be followed with regard to development proposals that may affect them, are detailed in Wildlife and Countryside legislation.	Section 3.1.5	There are no SSSIs with marine components in the vicinity of the Project.
Marine energy deployments, that is wave and tidal deployments, may pose potential risks to the environment if inappropriately sited. However, the level of risk and ecological significance is largely unknown since, in particular, tidal stream and wave technologies are at a relatively early stage of development. Studies of tidal range technologies, including barrages, have indicated that these structures can have adverse impacts on migratory fish and bird species and on the hydrodynamics of the estuarine environments in which they are situated. To underpin the marine planning process further research is needed to develop a better understanding of the potential impacts that marine technologies might have on potentially sensitive environmental features. For example, adaptation and mitigation methods for such impacts may be supported by detailed monitoring programmes and co-ordinated research initiatives, including post deployment of devices.	Section 3.3.25	Impacts to hydrodynamics are considered in **Chapter 7, Metocean Conditions and Coastal Processes** and any potential impacts during the operation of the Project on benthic and intertidal ecology is considered in **Section 9.6.3.1** and **9.6.3.2**
Draft WNMP		
Proposals should demonstrate how they contribute to the protection, restoration and/or enhancement of marine ecosystems.	ENV_01: Resilient marine ecosystems	The Project will put in place mitigation to ensure minimal disturbance to and loss of habitats and species during construction via pre-construction surveys and micro-siting.
Proposals should demonstrate how they: ▪ avoid adverse impacts on individual Marine Protected Areas (MPAs) and the coherence of the network as a whole; ▪ have regard to the measures to manage MPAs; and ▪ avoid adverse impacts on non-marine designated sites.	ENV_02: Marine Protected Areas	Consideration of effects on MPAs is included within **Section 9.6**. Additionally, consideration of impacts to European Designated sites is provided in **Document MOR/RHDHV/DOC/0067,**

Policy Description	Reference	ES Reference
		Information to Support HRA.
Proposals should include biosecurity measures to reduce the risk of introducing and spreading invasive non-native species.	ENV_03: Invasive non-native species	As a means of mitigation, an INNS risk assessment, to be undertaken once installation vessels and construction/manufacturing ports have been identified. Development of an outline Invasive Species and Biosecurity Management Plan (ISBMP) is suggested (**Section 9.6.2.5**). An outline Invasive and Non-Native Species (INNS) Management Plan has been submitted as part of this application (**Document MOR/RHDHV/DOC/0075, INNS Management Plan**).
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative impacts are assessed in **Section 9.6.5** and in **Chapter 26**
Anglesey and Gwynedd Joint Local Development Plan (JLDP)		
All impacts on landscape character, heritage assets and natural resources have been adequately mitigated, ensuring that the special qualities of all locally, nationally and internationally important landscape, biodiversity and heritage designations, including, where appropriate, their settings are conserved or enhanced	Policy ADN 3: Other Renewable Energy and Low Carbon Technologies	The impact assessment is included within **Section 9.6** and includes mitigation measures to reduce impact significance.
It does not cause unacceptable harm to: iv. the area's biodiversity interests (including European Protected Areas such as marine Special Areas of Conservation and Special Protected Areas) due to their location, scale, form, appearance, materials, noise, or emissions or due to an unacceptable increase in traffic.	Policy AMG 4: Coastal Protection	Valued Ecological Receptors are discussed in **Section 9.5.5**, designated sites **in Section 9.5.6** and protected habitats and species in **Section 9.5.7**. Potential impacts to these are assessed throughout **Sections 9.6.2, 9.6.3** and **9.6.4**.
Proposals must protect and, where appropriate, enhance biodiversity that has been identified as being important to the local area	Policy AMG 5: Local Biodiversity Conservation	The Project will put in place mitigation to ensure minimal disturbance to and loss of habitats and species during construction via pre-construction surveys and micro-siting.

Policy Description	Reference	ES Reference
Wellbeing of Future Generations (Wales) Act 2015		
A nation which maintains and enhances a biodiverse natural environment with healthy functioning ecosystems that support social, economic and ecological resilience and the capacity to adapt to change (for example climate change).	A resilient Wales	The Project is assessed to have minor to negligible impacts on benthic and intertidal biodiversity (**Table 9-32**) while providing a source of renewable energy to communities.

9.3. CONSULTATION

16. Scoping and consultation have been ongoing throughout the EIA and have supported the scope of the baseline characterisation work and ensuring that the requirements of the regulators and their advisors are met. **Table 9-3** summarises relevant consultation responses on the offshore elements of the Project received prior to and during preparation of the ES and which were considered in this Chapter. A full list of consultation responses and how they have been taken into account in finalising the Project is presented in **Chapter 6, Consultation**.

Table 9-3 Summary of Consultation Responses with Statutory Consultees Relating to Benthic and Intertidal Ecology

Consultee	Comment	Response
Planning Inspectorate	▪ *Sabellaria alveolata* and *Modiolus modiolus* reef: The Scoping Report notes the potential for *Sabellaria alveolata* and *Modiolus modiolus* reef to be present in the offshore scoping area. The Applicant should take into account NRW's response (see Appendix 1 of Scoping Opinion) stating that several areas of *Sabellaria alveolata* have developed into Sabellaria reef. Any likely significant effects on Sabellaria reef should be assessed within the ES. The ES should consider potential direct impacts from construction and also the potential impacts from maintenance activities on reef that may colonise the cables during the operational phase.	*Sabellaria alveolata* and *Modiolus modiolus* reef is considered within **Section 9.5.7** and **Sections 9.6.2, 9.6.3** and **9.6.4** of this chapter.
Planning Inspectorate	▪ Annex I habitats: The Scoping Report states that "there are no SAC or Annex I habitats identified within the offshore scoping area". NRW's response (see Appendix 1 of Scoping Opinion) states that Annex I Reef habitat is present within the zone. The ES should assess impacts to Annex I habitats where significant effects are likely to occur.	Annex I habitats are discussed within **Section 9.5.5** and considered throughout **Sections 9.6.2, 9.6.3** and **9.6.4** of this chapter.
Planning Inspectorate	▪ Section 7 marine habitats and species: Section 7 marine habitats and species which could be impacted by the Proposed Works should be acknowledged within the ES and an assessment of likely significant effects upon them should be	Marine habitats and species have been assessed throughout **Sections 9.6.2, 9.6.3** and **9.6.4**of this chapter. A differentiation between the

Consultee	Comment	Response
	undertaken. The ES should assess and differentiate between likely significant effects to intertidal and subtidal ecology.	Benthic Biological Environment and the Intertidal Biological Environment has been made within **Section 9.5.3.1**, **Section 9.5.3.2** and throughout **Impact Assessment.**
Planning Inspectorate	▪ Loss of habitat due to infrastructure footprint: It is understood that the type and locations of TEC devices within the offshore area will not be determined by the time of application. As such, the ES should consider a worst-case scenario of habitat loss. When assessing the potential impacts from loss of habitat, the ES should also give consideration to habitat loss resulting from the introduction of any scour and cable protection.	Loss of habitat due to infrastructure footprint has been assessed throughout **Sections 9.6.2, 9.6.3** and **9.6.4,** within the operational and maintenance phase and during the decommission phase of the Project. Temporary Habitat Disturbance has been assessed at all phases.
Planning Inspectorate	▪ Construction phase impacts: Potential construction phase impacts identified in Table 8-4 of the Scoping Report are equally applicable for the decommissioning phase and should be assessed as such in the ES.	Construction phase impacts are considered within **Section 9.6.2** of this chapter.
Planning Inspectorate	▪ Potential impacts: The ES should assess the likely significant effects from pollution from accidental spillages, impacts due to changes in water movements and changes in habitat type.	Release of pollutants due to accidental events is considered within **Section 9.6.2.3**.
Planning Inspectorate	▪ Impacts to benthic communities due to changes in sediment regime: Potential impacts due to change in sediment regime are included in Table 8.4. However, Table 8-2 identifies potential impacts to benthic ecology interest features of designated marine and coastal sites due to changes in coastal processes, sedimentology and hydrodynamic regime in Table 8-2. The ES should assess the likely significant effects on intertidal and subtidal benthic ecology from changes to physical process (e.g. alteration to flow conditions, waves regime and sediment transport pathways).	Increased suspended sediment concentration and sediment deposition is considered within **Section 9.6.2.2.**
Planning Inspectorate	▪ EIA Baseline Characterisation: The Applicant should consider the applicability of existing data to the Proposed Works. The Scoping Report explains that ecology characterisation surveys may potentially be required. It is recommended that the sufficiency of any existing data, and the need for any site-specific surveys, is discussed with NRW.	A Subtidal Survey (**Section 9.4.4.2**) and Intertidal Survey (**Section 9.4.4.3**) were conducted to support the impact assessment within this chapter.

Consultee	Comment	Response
	NRW's comments (see Appendix 1 of this Scoping Opinion) regarding the need for subtidal and intertidal surveys should be taken into account by the Applicant.	
Planning Inspectorate	▪ EIA Baseline Characterisation: The ES should explain how the sensitivity of benthic receptors sensitive to smothering and disturbance is determined, for example if it based on research or guidance. The ES should also take into account the sensitivity of benthic receptors to the other potential impacts identified in Table 8-4 of the Scoping Report.	The sensitivity of receptors is discussed in **Section 9.5.5**, and habitats and biotopes have been aggregated into Valued Ecological Receptors groups to allow for a streamlined assessment.
Planning Inspectorate	▪ Colonisation of structures: The ES should assess any likely significant effects from the colonisation of hard structures by non-native species.	Introduction of new habitat is considered within **Section 9.6.3.3**Operation Impact 3: Introduction of New Habitat in the Form of Project Infrastructure**.**
NRW	▪ Reference has been made to the HABMAP dataset (see Section 8.2) in relation to the benthic habitats that are within and adjacent to the Morlais demonstration zone. Whilst this is valid, it should be recognised that the confidence with which the HABMAP biotopes have been predicted is generally low to moderate. Comprehensive survey data does not exist for the demonstration zone, although there are some records in the Marine Recorder database which should be examined and incorporated into the summary. The ES must include an assessment of the confidence in the available data, as detailed in Schedule 3 of the MWR.	Survey data has been used to generate a greater understanding of the MDZ and surrounding environment, as presented throughout **Section 9.5**.
NRW	▪ There are a number of factual inaccuracies in Section 8.2.1.1 which must be corrected in the ES. Page 79 states that "there are no SAC or Annex I habitats identified within the offshore scoping area….". This is incorrect, as HABMAP predicts several rock biotopes and also coarse sediments and mixed sediments, which in some cases may form stony reef. In addition, data in Marine Recorder confirms the presence of Annex I Reef habitat within the zone. It is likely that Annex 1 rocky reef and / or stony reef will be present within the demonstration zone, and / or export cable corridor.	Following the survey conducted by OEL, all three reef Annex I habitats were observed, as discussed within **Section 9.5**.
NRW	▪ References to "*Sabellaria alveolata*" should be changed to "*Sabellaria* spp". Recent survey work by NRW TE in and around North and West Anglesey found several areas of developed Sabellaria reef.	Reference to *S. spinulosa* is used throughout this chapter, following survey data obtained by OEL.

Consultee	Comment	Response
	Video analysis, though inconclusive from a species identification point of view, appears to show a mix of both *S. alveolata* and *S. spinulosa* present in the elevated reef structures. It is therefore likely that any similar reef aggregations found within the zone will contain a mixture of Sabellaria species.	
NRW	▪ Section 7 (formerly BAP / Section 42) marine habitat records are present within or near the Morlais Demonstration Zone. These include *Musculus discor*s beds (two records to the North of Holyhead from 1996), seagrass (recent and historic records) in shallow water on the east and west sides of Holy Island (outside of the zone but potentially within the wider zone of impact) and fragile sponge and anthozoan communities both within and adjacent to the zone. Section 7 subtidal mixed muddy sediments, and subtidal sands and gravels are also predicted to occur in and adjacent to the zone, along with patches of Annex 1 rocky reef (survey records and BGS hard substrate map). The Section 7 species *Arctica islandica and Haliclystus auricular* have also previously been found in shallow waters off Holy Island (MNCR records from 1996) and may occur within the zone. These habitats and species must be acknowledged and considered in the EIA.	Section 7 marine habitat records are discussed within **Section 9.5.7.**
NRW	▪ It is difficult to comment on the potential impacts outlined in Table 8.4 due to the range of unknowns associated with such a broad PDE approach. Impacts will depend on the number, size and types of devices put in place. The table currently states “significance of impact unknown” in the “anticipated significance” column for many impact pathways. The potential impacts listed are quite broad and will need to be subdivided into specific parts for the EIA (for example, “impact to benthic communities due to the creation of sediment plumes during construction” could cause impacts both through increases in suspended sediment and also increases in sediment deposition). Some of the impact pathways that are missing include (but are not limited to) pollution from accidental spillages, impacts due to changes in water movements and changes in habitat type. A full assessment of potential impacts needs to be undertaken in the EIA.	A full assessment has been presented within **Chapter 7, Metocean Conditions and Coastal Processes**, and within **Section 9.6.2.2.**
NRW	▪ Specifically, in Table 8.4, the impact pathway identified as “impact to benthic communities due to	This impact has been assessed within **Section**

Consultee	Comment	Response
	the creation of sediment plumes during construction" is assessed as "effects unlikely to be significant". However, the comment for this impact states that the significance of impact would depend on the sensitivity of the local benthic habitats as well as the nature of sediment dispersal. In light of this fact, the significance level should be considered "unknown" until further knowledge of the benthic communities present is attained via site specific surveys.	**9.6.2.2** of this chapter following collation of survey data and extensive coastal processes modelling.
NRW	▪ We welcome the acknowledgement of potential impacts to benthic ecology interest features of designated marine and coastal sites due to changes in coastal processes, sedimentology and hydrodynamic regime in Table 8.2. We note, however, that only potential impacts due to change in sediment regime are included in Table 8.4 'Potential impacts on benthic ecology'. As noted in the Metocean Conditions and Coastal Processes section of this Opinion, we have raised some comments relating to coastal process aspects of the Scoping Report which will have consequences for benthic ecology. Specifically, we would welcome clarity on how the potential impacts to the physical processes caused by the deployment of multiple tidal energy devices and associated infrastructure will be adequately assessed using a non-numerical (conceptual model) approach, and how this will be applied in the context of potential impacts to intertidal and subtidal benthic ecology, water quality and coastal morphodynamics arising due to physical process impacts (alteration to flow conditions, waves regime and sediment transport pathways).	This impact has been assessed within **Section 9.6.2.2** of this chapter following collation of survey data and coastal processes modelling as detailed within **Chapter 7, Metocean Conditions and Coastal Processes**.
NRW	▪ The text in the EIA baseline characterisation section (Section 8.2.3) does not specifically state how further information will be obtained on the benthic habitats and species within the demonstration zone. Survey work is only mentioned as potentially being required. We advise that a targeted ground-truthing survey is carried out within the demonstration zone to properly characterise the area in terms of subtidal ecology (we understand that multibeam data already exists for the marine development area). This would reduce uncertainty as to the presence of sensitive features or receptors in the area. NRW TE can provide guidance on the interpretation and ground truthing of acoustic data (multibeam and side scan) for ecological	A Subtidal Survey (**Section 9.4.4.2**) and Intertidal Survey (**Section 9.4.4.3**) were conducted to support the Impact Assessment within this chapter.

Consultee	Comment	Response
	purposes and can advise on the scope of such surveys if required.	
NRW	▪ We note that the Offshore Scoping Zone now includes the sea area between the demonstration zone and the shore. Additional multibeam / acoustic survey and benthic ground-truthing will be needed in this area to inform the benthic impact assessment associated with the export cable route from the Lease Area if not already available.	A Subtidal Survey (**Section 9.4.4.2**) and Intertidal Survey (**Section 9.4.4.3**) were conducted to support the Impact Assessment within this chapter.
NRW	▪ The intertidal ecology section (Section 8.2.1.2) is very brief. The inclusion of an intention to 'assess' CCW Phase 1 habitat survey data, as part of the applicant's data gathering exercise to inform EIA baseline characterisation, is welcomed. This information needs to be presented in a similar way to the subtidal section (see Table 8.3) and assessed against a realistic worst-case scenario for the anticipated installation method, landfall location and spatial extent of the export cables.	A Subtidal Survey (**Section 9.4.4.2**) and Intertidal Survey (**Section 9.4.4.3**) were conducted to support the Impact Assessment within this chapter.
NRW	▪ With regards to the proposed export cable landfall location, the ES must include a detailed assessment of potential impacts to the intertidal habitats present in and around the Penrhos Feilw area. We recommend that, in order to inform baseline/characterisation of the intertidal zone at the proposed landfall location, the applicant undertakes a repeat of the Phase 1 intertidal habitat survey at an appropriate scale for the planned works.	Physical disturbance to intertidal habitats and species during landfall works is assessed within **Section 9.6.2.4**.
NRW	▪ We welcome the recognition in Table 11.1 that a thorough biosecurity risk assessment should be undertaken as part of the EIA process. The ES and associated biosecurity risk assessment should include consideration of how *Didemnum vexillum* will be contained within the marina and detail any measures to mitigate the onward spread of this species. This is particularly important if, during any stage of the development (construction, operation, decommissioning), the applicant intends to use the facilities at Holyhead marina or port for berthing of vessels, materials or equipment.	Discussion of *Didemnum vexillum* is presented within **Section 9.5.8** and **Section 9.6.2.5.** An assessment of INNS has been undertaken within **Section 9.6.2.5**. As a means of mitigation, an INNS risk assessment, to be undertaken once installation vessels and construction/manufacturing ports have been identified. Development of an ISBMP is suggested. An outline INNS Management Plan has been submitted as part of this application (**Document MOR/RHDHV/DOC/0075, INNS Management Plan**).

9.4. METHODOLOGY

9.4.1. Impact Assessment Methodology

17. A detailed description of the methodology employed within this chapter is described within **Chapter 5, EIA Methodology.**

18. The assessment approach has adopted the following stages:

- Review of existing relevant data and information;
- Acquisition of additional project-specific data to fill any gaps;
- Formulation of a conceptual understanding of baseline conditions;
- Consultation and agreement with the regulators regarding proposed assessment approaches;
- Determination of the worst-case scenarios;
- Consideration of embedded mitigation measures; and
- Assessment of effects using data analysis, numerical modelling outputs, and expert-based judgements by MarineSpace Ltd.

19. The assessment of effects on subtidal and intertidal ecology is predicated on a Source-Pathway-Receptor (S-P-R) conceptual model, whereby the source is the initiator event, the pathway is the link between the source and the receptor impacted by the effect, and the receptor is the receiving entity.

20. An example of the S-P-R conceptual model is provided by cable installation which disturbs sediment on the sea bed (source). This sediment is then transported by tidal currents until it settles back to the sea bed (pathway). The deposited sediment could smother and have an effect on the species on this area of the seabed (receptor).

21. Consideration of the potential effects of the Project is carried out over the following spatial scales:

- Near-field: the area within the immediate vicinity (tens or hundreds of metres) of the project and along the offshore export cable corridor (ECC); and
- Far-field: the wider area that might also be affected indirectly by the project (e.g. due to disruption of waves, tidal currents or sediment pathways).

22. Three main phases of development are considered over the life-cycle of the project, in conjunction with the present-day baseline. These are:

- Construction phase;
- Operation and maintenance phase (including repowering); and
- Decommissioning phase.

9.4.1.1. Sensitivity, Value and Magnitude

23. The sensitivity of a receptor is dependent upon its:

- Tolerance to an effect (the extent to which the receptor is adversely affected by an effect);
- Adaptability (the ability of the receptor to avoid adverse impacts that would otherwise arise from an effect); and
- Recoverability (a measure of a receptor's ability to return to a state at, or close to, that which existed before the effect caused a change).

24. In addition, a value component may also be considered when assessing a receptor. This ascribes whether the receptor is rare, protected or threatened.

25. The magnitude of an effect is dependent upon its:

- Scale (i.e. size, extent or intensity);
- Duration;
- Frequency of occurrence; and
- Reversibility (i.e. the capability of the environment to return to a condition equivalent to the baseline after the effect ceases).

26. The sensitivity and value of receptors and the magnitude of effect are assessed using expert judgement and described with a standard semantic scale. Definitions for each term are provided in **Table 9-4** to **Table 9-6**. These expert judgements of receptor sensitivity, value and magnitude of effect are guided by the conceptual understanding of baseline conditions.

Table 9-4 Definitions of Sensitivity Levels for an Ecological Receptor

Sensitivity	Definition
High	Tolerance: Receptor has very limited tolerance of effect Adaptability: Receptor unable to adapt to effect Recoverability: Receptor unable to recover resulting in permanent or long-term (greater than ten years) change
Medium	Tolerance: Receptor has limited tolerance of effect Adaptability: Receptor has limited ability to adapt to effect Recoverability: Receptor able to recover to an acceptable status over the medium term (5-10 years)
Low	Tolerance: Receptor has some tolerance of effect Adaptability: Receptor has some ability to adapt to effect Recoverability: Receptor able to recover to an acceptable status over the short term (1-5 years)
Negligible	Tolerance: Receptor generally tolerant of effect Adaptability: Receptor can completely adapt to effect with no detectable changes Recoverability: Receptor able to recover to an acceptable status near instantaneously (less than one year)

Table 9-5 Definitions of the Different Value Levels for an Ecological Receptor

Value	Definition
High	Value: Receptor is designated and/or of national or international importance for marine geology, oceanography and physical processes. Likely to be rare with

Value	Definition
	minimal potential for substitution. May also be of significant wider-scale, functional or strategic importance
Medium	Value: Receptor is not designated but is of local to regional importance for marine geology, oceanography and physical processes
Low	Value: Receptor is not designated but is of local importance for marine geology, oceanography and physical processes
Negligible	Value: Receptor is not designated and is not deemed of importance for marine geology, oceanography and physical processes

Table 9-6 Definitions of Magnitude of Effect Levels for an Ecological Receptor

Magnitude	Definition
High	Scale: A change which would extend beyond the natural variations in background conditions Duration: Change persists for more than ten years Frequency: The effect would always occur Reversibility: The effect is irreversible
Medium	Scale: A change which would be noticeable from monitoring but remains within the range of natural variations in background conditions Duration: Change persists for 5-10 years Frequency: The effect would occur regularly but not all the time Reversibility: The effect is very slowly reversible (5-10 years)
Low	Scale: A change which would barely be noticeable from monitoring and is small compared to natural variations in background conditions Duration: Change persists for 1-5 years Frequency: The effect would occur occasionally but not all the time Reversibility: The effect is slowly reversible (1-5 years)
Negligible	Scale: A change which would not be noticeable from monitoring and is extremely small compared to natural variations in background conditions Duration: Change persists for less than one year Frequency: The effect would occur highly infrequently Reversibility: The effect is quickly reversible (less than one year)

9.4.1.2. Impact Significance

27. Following the identification of receptor sensitivity and value, and magnitude of effect, it is possible to determine the significance of the impact. A matrix is presented in **Table 9-7** as a framework to guide how a judgement of the significance is determined.

Table 9-7 Impact Significance Matrix

		Negative Magnitude				**Beneficial Magnitude**			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

28. Through use of the matrix shown in **Table 9-7** an assessment of the significance of an impact can be made in accordance with the definitions in **Table 9-8**.

Table 9-8 Impact Significance Definitions

Impact Significance	Definition
Major	Very large or large change in receptor condition, both adverse or beneficial, which are likely to be important considerations at a regional or district level because they contribute to achieving national, regional or local objectives, or, could result in exceedance of statutory objectives and / or breaches of legislation
Moderate	Intermediate change in receptor condition, which is likely to be an important consideration at a local level
Minor	Small change in receptor condition, which may be raised as a local issue but is unlikely to be important in the decision-making process
Negligible	No discernible change in receptor condition

29. For the purposes of this ES, ‘major’ and ‘moderate’ impacts are deemed to be significant (in EIA terms). In addition, whilst ‘minor’ impacts may not be significant, it is important to distinguish these from other non-significant (negligible) impacts as they may contribute to significant impacts cumulatively.

9.4.1.3. Cumulative Impact Assessment

30. Cumulative impacts are assessed through consideration of the extent of influence of changes to intertidal and benthic ecology arising from the project alone and those arising from the project cumulatively or in combination with other developments including the adjacent Deep Green (DG) Holyhead Deep Tidal Array project. The Scoping Report proposes that the export cable from the DG Holyhead Deep Tidal Array project will link with that of the Morlais Project and that both projects have a joint landfall.

9.4.2. Study Area

31. Study areas are defined for each topic at the relevant scale. These are determined by a number of factors such the distribution of receptors, footprint of potential impact, or perhaps political/management boundaries (e.g. territorial waters, ICES rectangles) and where possible these were agreed with regulators or advisors.

The MDZ is in the eastern Irish Sea, encompassing a sea bed area of approximately 39 km^2. Its nearest point is located approximately 0.5 km from the west coast of Anglesey. Export cables connect the Project across an offshore export cable corridor (ECC) to the east of the MDZ and then to the landfall at Abraham’s Bosom near Penrhos Feilw (**Figure 1-1, Volume II**). The benthic and intertidal study area encompasses the entirety of the offshore site (both the development site and the export cable route), as the footprint of the Project and associated engineering works has the potential to impact benthic ecology within these areas.

9.4.3. Data Sources – Desk Study

32. Prior to site-specific surveys, a detailed desk-based study was conducted. A comprehensive review of available information was conducted to support the scope of works, survey design and

regional characterisation. The resources from which detail were extracted included, but were not limited to:

- Marine Life Information Network (MarLIN);
- Consultation responses;
- UK SeaMap data 2010 (McBreen et al., 2011);
- British Geological Survey (BGS) data; and
- Published and unpublished literature.

9.4.4. Data Sources – Site-specific Surveys and Reports

9.4.4.1. Project-Specific Benthic and Intertidal EIA Characterisation Survey

33. To characterise the benthic ecology of the offshore site and the surrounding area, and to support the identification of possible Habitats Directive Annex I/II habitats/species, subtidal and intertidal surveys were conducted capturing ecological data. These surveys were conducted by OEL and involved the collection of marine data including high resolution seabed imagery, grab samples, core samples, quadrat data and aerial imagery to enable the collation of a detailed biotope map of the MDZ.

34. Site specific surveys were conducted in summer 2018 by OEL (Ocean Ecology, 2018), which aimed to characterise the benthic and intertidal ecology. Details of these surveys are described within **Table 9-9** with survey specific details, and sample site location displayed within **Figure 7-2** (**Volume II**). Sampling stations for general seabed classification purposes were spread throughout the survey area to ensure representative coverage of all predicted habitats identified in the review of geophysical data.

Table 9-9 Summary of Site-Specific Surveys Conducted to Support the Development of this ES Chapter

Survey Date	Survey Type	Key Outputs
4/09/2018 – 06/09/2018	Subtidal survey	42 subtidal DDV sample stations collecting 277 still images and 220 minutes of video footage; and Five grab sample stations for particle size analysis and in-situ faunal analysis.
30/08/2018	Intertidal survey	UAV mapping collected 243 high resolution nadir images across 500 m wide area; and Intertidal walkover survey of the Project cable landfall area.

35. A breakdown of all grab and camera sampling is presented within **Table 9-10**. A total of 227 still images and over 220 minutes of video data were collected from 42 subtidal sampling stations within the study area. Only four grab samples were obtained from the proposed 18 target stations, due to unsuitable substrate types across the majority of the sampling array. As the intertidal zone was dominated by hard substrate, the majority of the sampling was conducted using a 0.25 m^2 quadrat with the collection of two core samples.

9.4.4.2. Subtidal Survey

36. A subtidal survey array was developed around a diamond grid of sampling stations (**Figure 7-3, Volume II**) to allow a seabed biotope map to be produced for the benthic ecology requirements

of the EIA (Hitchin et al. 2015, Turner et al. 2015). Additional stations were added and located at potential transitions between substrates at key areas of development (along the cable corridor and Abraham's Bosom), and within a 1km buffer zone up- and down-stream of the development. Selection of these areas was aided by an initial interpretation of sidescan sonar backscatter, allowing for suitable substrates to be surveyed. The proposed survey designs were further sense checked against project-specific acoustic sidescan sonar and multibeam echo sounder data collected in 2018 by Partrac (Partrac, 2018).

37. The subtidal survey was completed between the 4th and 6th September 2018 and was comprised of 42 ground truthing stations across the Project area (including the buffer area and proposed cable corridors). At each of these stations, a drop-down camera (DDC) was deployed to collect seabed imagery data. Sediment samples were proposed to be collected at 18 grab sample stations, allowing for analysis of particle size and in-situ faunal analysis to aid biotope mapping. Due to substrate types, grabs were only collected from four of these 18 stations.

Table 9-10 Grab and Drop-Down Camera Sampling Undertaken During the Morlais Demonstration Zone Benthic Ecology Characterisation 2018 Survey

Location	Grab Samples (Macrobenthic and PSF Sub-Sample)	Drop Down Camera (DDC) Stations
Morlais Demonstration Zone	1	33
Associated buffer area	2	6
South cable corridor	1	3
Total	**4**	**42**

9.4.4.3. Intertidal Survey

38. The intertidal survey was undertaken during the spring tides on the 30th August in line with guidance in the Marine Monitoring Handbook (Davies *et al*., 2001) and CCW Handbook for Marine Intertidal Phase I Survey and Mapping (Wyn *et al*., 2006). Biotopes were classified according to the EUNIS classification (Parry, 2015) and were also correlated to the Marine Nature Conservation Review (MNCR) biotope classification. Boundaries of biotopes were recorded in areas where this was possible. The methods described below are those described within the survey report produced by OEL (Ocean Ecology Ltd, 2018).

39. This survey was conducted in two phases around the proposed cable landfall at Abraham's Bosom. In phase one, an Unmanned Aerial Vehicle (UAV) was flown at low tide to capture high-resolution aerial imagery which aided the generation of ortho-mosaic mapping. Each flight was planned to achieve a minimum resolution of 5 cm/pixel with an accuracy of 5-10 m and flown by qualified UAV Pilots (RPQs) under a Permission for Commercial Operations (PfCO) granted to OEL by the Civil Aviation Authority (CAA). All flights were conducted in line with relevant CAA regulations (Cap 722, 2015) with received permission from RSPB.

40. This process allowed for identification of key habitats during the Phase I intertidal walk over survey conducted during a second visit to ground-truth biotope boundaries and cryptic biotopes. For any soft sediments identified in the UAV mapping and/or walk over survey, a series of quadrat sampling stations were sampled to further inform subsequent biotope mapping.

41. Areas representative of each key hard substrate habitat at different tidal heights were assessed by recording the epibiota taxa present in randomly placed 0.04 m^2 (0.2 m x 0.2 m) quadrats. Identification was taken to species level where possible and undertaken in the field. Areas representative of each key soft sediment habitat were assessed by sampling the upper 10 cm of a 0.04 m^2 (0.2 m x 0.2 m) quadrat using a spade and screened on a 0.5 mm sieve. Any macrobenthos retained on the sieve was identified to species level where possible in the field. The quadrats were then dug to c. 30 cm depth to check for the presence of larger, burrowing species. All soft sediment samples were also subject to a visual inspection and observations of colour, smell, depth of RPD layer, texture and presence of surface features (accretions, algae, fauna, etc.) recorded.

9.5. EXISTING ENVIRONMENT

42. This section provides an overview of the baseline ecological environment in relation to the benthic and intertidal study area associated with the Project. This section provides details of species and habitats associated with the MDZ and wider area, while identifying those which may be of particular conservation concern. The characterisation of the existing environment is undertaken using the aforementioned data sources listed in **Section 9.4.3** and **Section 9.4.4** sections and the site-specific survey data, plus other relevant literature.

9.5.1. Regional Context

43. Within the wider Irish Sea, relatively shallow depths are observed of around 20-100 m over considerable areas. A deeper channel running north-south is located to the west of the Irish Sea exists, connecting the Irish Sea to the Celtic Sea via St George’s Channel and the Malin Shelf via the North Channel (Vincent et al., 2004).

44. A diverse array of seabed types are observed within Irish Sea, from gravelly sediments occurring extensively across a broad central belt (usually in areas exposed to strong tidal currents); mobile sands and megaripples around the coast of the Isle of Man, Liverpool Bay, Cardigan Bay and in St George’s Channel; two areas of muddy sediments in the northern half and exposed bedrock locally in the North Channel and between Anglesey and the Isle of Man (Boelens et al., 1999).

45. Around the coast of Anglesey, extensive platforms of pre-Cambrian rock expand up to 25 km offshore. The seabed in the north of Anglesey is characterised by exposed bedrock, or bedrock thinly overlain by boulders and gravels in a patchy composition (Rees, 2005). The intertidal areas around Anglesey are extensive areas of relatively undisturbed habitats comprised of high energy rocky shores, sea cliffs, coastal heathlands and coastal grazing. The west of Anglesey, where the export cable will landfall, has substantial areas of exposed shores which are largely coastal cliff headlands with beaches comprise of moderate coarse sediments. The benthic communities around the Project are typically common in the Anglesey area and the wider Welsh coastal regions. These communities are typically comprised of common polychaetes, crustaceans, molluscs and echinoderms.

46. Section 7 (formerly BAP / Section 42) marine habitat records are present within or near the MDZ. These include *Musculus discors* beds (two records to the North of Holyhead from 1996), seagrass (recent and historic records) in shallow water on the east and west sides of Holy Island (outside of the zone but potentially within the wider zone of impact) and fragile sponge and

anthozoan communities both within and adjacent to the zone. Section 7 subtidal mixed muddy sediments, and subtidal sands and gravels are also predicted to occur in and adjacent to the zone, along with patches of Annex 1 rocky reef (survey records and BGS hard substrate map). The Section 7 species *Arctica islandica* and *Haliclystus auricular* have also previously been found in shallow waters off Holy Island (MNCR records from 1996) and may occur within the zone.

9.5.2. Physical Environment

47. Water depths across the MDZ and export cable corridor vary between approximately -2 m CD at the landfall and -72 m CD in the northwest part of the MDZ (**Figure 7-1, Volume II**) (Partrac, 2018). The average depth across the MDZ is approximately 40 m.

48. Most of the sea bed comprises large areas of outcropping bedrock with minimal relief above surrounding bed levels. Secondary bathymetric features include a large, generally symmetric, sand ridge north of South Stack which extends to the northwest for approximately 1 km (within the offshore cable corridor). The crest of the ridge is about 8 m to 10 m higher than the surrounding sea bed. Several smaller ridges oriented parallel to the main ridge occur to its north-northeast. Within Abraham's Bosom (a bay towards the landfall), the bathymetry is smoother, representing the surface of an area of sediment on top of the bedrock, bounded by rock outcrops to the north and south.

49. At a more local scale the sea bed is uneven due to the presence of bedforms of various sizes. Megaripples occur close to Abraham's Bosom within the offshore cable corridor. They are up to 0.6 m high, up to 12.8 m wavelength, with crests oriented approximately west-east, indicative of north-south tidal currents. Larger fields of megaripples occur in the south and southwest parts of the MDZ, where they are up to 0.6 m high, up to 12.9 m wavelength, with crests oriented approximately west-east.

50. Given the semi-enclosed nature of the Irish Sea, most oceanic swell waves are prevented from reaching the Anglesey coastline through St George's Channel and from the north due to the shelter provided by the Isle of Man. As a result, waves arriving at the Anglesey coastline are predominantly wind generated within the Irish Sea (Royal HaskoningDHV, 2011). The fetch between Ireland and Wales is generally less than 100 km, limiting the height that waves can grow from the west. The largest fetch originates from a southwest direction, where the fetch can reach thousands of kilometres into the Atlantic Ocean. Further details of the physical details of the area surrounding the MDZ are presented within **Chapter 7, Metocean Conditions and Coastal Processes**.

9.5.2.1. Seabed Sediment Distribution

51. Throughout most of the northern, central and eastern parts of the MDZ the sea bed is dominated by outcropping bedrock with thin patches of sandy gravel, whereas the deeper western part comprises relatively uniform gravel or gravelly sand.

52. Following the collection of video and still image data from the 42 subtidal sampling stations, only five of the 18 target sampling stations were deemed suitable for grab sampling due to the hard substrate present resulting the in the acquisition of just four grab samples. Only one sea bed

sediment sample (location 41) was recovered from the MDZ, on its eastern boundary, northwest of South Stack (Ocean Ecology, 2018). This low level of successful sediment sampling reflected the predominantly hard seabed substrate across the survey area. Two samples were collected in the buffer zone, one north of South Stack (location 15) and one to the south of the MDZ (location 20). One sample (42) was collected along the landward part of the offshore cable corridor in Abraham's Bosom (Ocean Ecology, 2018).

53. The dominant sediment type in sample 41 is gravel (73%) with 27 % sand, with a median particle size of about 3.8 mm. In samples 15 and 20, the dominant component is sand (89-93 %) with a median particle size of 0.63 mm and 0.75 mm (both coarse sand) (Folk, 1954) (**Table 9-11**). The particle size characteristics of sample 42 were dominated sand (96 %) with a median particle size of about 0.41 mm (medium sand). This sample falls within the Abraham's Bosom sediment deposition zone identified by Partrac (2018).

Table 9-11 Particle Size Characteristics of Sea Bed Sediment Samples in the MDZ and Buffer Zone. Data from Ocean Ecology (2018)

Station	Gravel (%)	Sand (%)	Mud (%)	d_{50} (mm)
41	73	27	0	3.8
15	9	89	2	0.63
20	7	93	0	0.75
42	0	96	4	0.41

9.5.3. Biological Environment

9.5.3.1. Benthic Biological Environment

54. A total of 42 subtidal sampling stations were targeted allowing for the collection of 277 still images and over 220 minutes of video footage. Of the 18 target sample stations for benthic grabs, only five were deemed suitable due to the presence of hard substrate. Therefore, only four grab samples were obtained within this survey.

55. Due to the prevalence of hard substrate across the survey area very few grab and core samples were acquired during the subtidal and intertidal surveys demonstrating the limited extent of sediment habitats across MDZ. The few samples that were acquired were seemingly impoverished with a maximum of six taxa and nine specimens recorded in any one sample.

9.5.3.2. Intertidal Biological Environment

56. The dominance of hard substrate in the intertidal zone meant that the majority of intertidal sampling involved 0.25 m^2 quadrat sampling (18 stations) and the collection of just two core samples. The UAV mapping survey resulted in the collection of 243 high resolution nadir images across a 500 m wide area of the intertidal area.

57. The intertidal survey area was found to support a wide variety of littoral rock biotopes interspersed with discrete patches of barren shingle and occasional areas of sandy sediment. Biotopes within the intertidal zone were those which are typically associated with a high energy intertidal area, such as *Mytilus edulis* and barnacles on very exposed eulittoral rock, *Semibalanus balanoides*, *Patella vulgata* and *Littorina* spp. on exposed to moderately exposed

or vertical sheltered eulittoral rock, *Fucus* spp. on exposed to moderately exposed upper eulittoral rock and Fucoids and kelp in deep eulittoral rockpools.

9.5.4. Biotope Classification and Mapping

58. The subtidal environment within and surrounding the MDZ was found to be constituted by a complex assortment of subtidal biotope mosaics dominated by circalittoral and/or infralittoral rock and coarse sediments. A total of 28 intertidal and 15 subtidal EUNIS biotopes were mapped across the survey area based on a comprehensive synthesis of all information collected during the survey and all available existing information including geophysical data and existing biotope mapping. A summary of all intertidal and subtidal biotopes is mapped in **Figure 9-1** and **Figure 9-2** (**Volume II**), and also displayed within **Table 9-12**.

59. The deeper areas of the site were characterised by coarse sediments (A5.14) representative of Annex I stony reef habitat (as per Irving, 2009) frequently overlain by varying coverage of *Sabellaria spinulosa* tube aggregations representative of Annex I biogenic reef in some areas (as per Gubbay, 2007) (A4.22). The amount of overlying sediment was reduced in the slightly shallower waters in central, southern and northern areas where tide-swept and mixed faunal turf communities (A4.11 / A4.13) representative of Annex I bedrock reef were prevalent. Closer to shore sediment biotopes dominated grading from coarse gravels (A5.14) to subtidal sands (A5.2) in Abraham's Bosom transitioning into macrophyte dominated infralittoral rock in the shallow subtidal and sublittoral fringes across the whole area (A3.1111, A3.1112, A3.2111). **Plate 9-1** illustrates images of biotopes observed within across the MDZ survey area.

60. Due to the hard nature of the seabed across most of the subtidal survey area, biotope mapping across this zone was largely informed by the results of the seabed imagery analysis and a detailed interpretation of the MBES and SSS data available for the site. This area was found to be constituted by a complex array of subtidal biotope mosaics dominated by circalittoral and/or infralittoral rock and coarse sediments. All three Annex I reef types (bedrock, stony and biogenic) were noted across this area.

61. The intertidal area supports a wide variety of littoral rock biotopes interspersed with discrete patches of barren shingle and occasional areas of sandy sediment. The graduation down the shore followed that of other exposed to moderately exposed shores with notable lichen and barnacle bands (B3.111, A1.112, A1.1131) in the supralittoral and upper-mid shore areas, especially in the more gradually inclining areas within the main bay areas, grading into fucoid and then kelp dominated rock biotopes.

62. Impoverished shingle (A2.111) was recorded in upper shore areas within the bays overlain by a narrow strandline biotope constituted by decomposing seaweed supporting sandhopper (*Talitrid* amphipods) communities (A2.211).

63. The gradation of biotopes observed in the bays was compressed into narrow bands in the southern and northern sections of the survey area due to the steep cliffs and vertical rock faces. All areas of littoral rock biotopes within the intertidal area were representative of Annex I bedrock reef as mapped in **Plate 9-1**.

64. Similar to the subtidal zone, the intertidal survey area was largely characterised by hard substrate meaning the majority of the biotope mapping was informed by quadrat data, UAV imagery and existing biotope mapping. The intertidal survey area was found to support a wide variety of littoral rock biotopes representative of Annex I bedrock reef interspersed with discrete patches of barren shingle and occasional areas of sandy sediment.

Table 9-12 Biotopes Identified within the Survey Area (Ocean Ecology, 2018)

EUNIS Code	JNCC Marine Habitats Classification Biotope Code	Biotope Description
A1.1	LR.HLR	High energy littoral rock
A1.111	LR.HLR.MusB.MytB	*Mytilus edulis* and barnacles on very exposed eulittoral rock
A1.112	LR.HLR.MusB.Cht.Cht	*Chthamalus* spp. on exposed upper eulittoral rock
A1.1131	LR.HLR.MusB.Sem.Sem	*Semibalanus balanoides*, *Patella vulgata* and *Littorina* spp.on exposed to moderately exposed or vertical sheltered eulittoral rock
A1.1132	LR.HLR.MusB.Sem.FvesR	*Semibalanus balanoides*, *Fucus vesiculosus* and red seaweeds on exposed to moderately exposed eulittoral rock
A1.123	LR.HLR.FR.Him	*Himanthalia elongata* and red seaweeds on exposed to moderately exposed lower eulittoral rock
A1.125	LR.HLR.FR.Mas	*Mastocarpus stellatus* and *Chondrus crispus* on very exposed to moderately exposed lower eulittoral rock
A1.212	LR.MLR.BF.FspiB	*Fucus spiralis* on exposed to moderately exposed upper eulittoral rock
A1.213	LR.MLR.BF.FvesB	*Fucus vesiculosus* and barnacle mosaics on moderately exposed mid eulittoral rock
A1.2141	LR.MLR.BF.Fser.R	*Fucus serratus* and red seaweeds on moderately exposed lower eulittoral rock
A1.311	LR.LLR.F.Pel	*Pelvetia canaliculata* on sheltered littoral fringe rock
A1.3141	LR.LLR.F.Asc.FS	*Ascophyllum nodosum* on full salinity mid eulittoral rock
A1.411	LR.FLR.Rkp.Cor	Coralline crust-dominated shallow eulittoral rockpools
A1.412	LR.FLR.Rkp.FK	Fucoids and kelp in deep eulittoral rockpools
A1.413	LR.FLR.Rkp.SwSed	Seaweeds in sediment-floored eulittoral rockpools
A1.444	LR.FLR.CvOv.RhoCla	*Rhodochorton purpureum* and *Cladophora rupestris* on upper to mid-shore cave walls
A1.4461	LR.FLR.CvOv.SpR.Den	Sponges, shade-tolerant red seaweeds and *Dendrodoa grossularia* on wave-surged overhanging lower eulittoral bedrock and caves
A1.451	LR.FLR.Eph.Ulv	Ulva spp. on freshwater-influenced and/or unstable upper eulittoral rock
A2.111	LS.LCS.Sh.BarSh	Barren littoral shingle
A2.2	LS.LSa	Littoral sand
A2.211	LS.LSa.St.Tal	*Talitrids* on the upper shore and strand-line
A2.211	LS.LSa.St.Tal	*Talitrids* on the upper shore and strand-line
A3.1	IR.HIR	High energy infralittoral rock
A3.1111	IR.HIR.KFaR.Ala.Myt	*Alaria esculenta*, *Mytilus edulis* and coralline crusts on very exposed sublittoral fringe bedrock

EUNIS Code	JNCC Marine Habitats Classification Biotope Code	Biotope Description
A3.1112	IR.HIR.KFaR.Ala.Ldig	*Alaria esculenta* and *Laminaria digitata* on exposed sublittoral fringe bedrock
A3.2111	IR.MIR.KR.Ldig.Ldig	*Laminaria digitata* on moderately exposed sublittoral fringe bedrock
A4.11	CR.HCR.FaT	Very tide-swept faunal communities
A4.13	CR.HCR.XFa	Mixed faunal turf communities

9.5.5. Valued Ecological Receptors

65. The value of ecological features is dependent upon their biodiversity, social and economic value within a geographic framework of appropriate reference (CIEEM, 2016). Identifying those habitats and species that have a specific biodiversity value recognised through international or national legislation, or through local, regional or national conservation plans (e.g. Annex I habitats under the Habitats Directive, Section 7 (formerly BAP/Section 42), existing and recommended Marine Conservation Zones (MCZ and rMCZ, respectively) is understood to be the most straightforward context for assessing ecological value. Under the existing legislative or policy framework, a very small proportion of marine habitats and species are afforded protection and therefore evaluation must also assess value according to the functional role of the habitat or species. For example, some features may not have a specific conservation value in themselves but may be functionally linked to a feature of high conservation value.

66. For the purpose of this environmental impact assessment, habitats with similar physical, biological characteristics as well as conservation status/interest have been grouped together. Consideration was also given to the inherent sensitivities of different habitats, such that habitats and species with similar vulnerability and recoverability, often as a result of similar broad sediment types and species complements, were grouped together. The biotopes and Annex I habitats within the MDZ have been split into 12 broad community and habitat types. These 12 Valued Ecological Receptors (VERs) represent the benthic and intertidal biological environment in and around the MDZ, and the impacts associated with this project have been assessed against these groups (**Table 9-13**).

67. **Figure 9-3** and **Figure 9-4** (**Volume II**) illustrate the location of the VER groups throughout the MDZ. The VER habitat groups 9 and 10 dominate the MDZ. These groups are both comprised of biotopes relating to Annex I reefs (biogenic, stony and bedrock). However, it should be noted that the VER groupings are not suggestive of definite presence, and therefore it cannot be assumed that Annex I reefs are present in all areas which are marked as habitat group 9 or 10.

Table 9-13 Criteria Valued Ecological Receptors within the Morlais Demonstration Zone (MDZ) Benthic Ecology Study Area, their Conservation Status and Importance.

9.5.6. Designated Sites

68. Due to the diverse array of habitats present within Anglesey and the wider area, the region hosts a variety of designated sites, illustrated within **Figure 9-5** (**Volume II**) and described within **Table 9-14**. These include Special Areas of Conservation (SAC), Special Protected Areas (SPA) and Ramsar sites.

69. There are no MCZs within close proximity to, or potentially impacted by, the proposed Project. The closest MCZ is over 100 km to the north east of the proposed site. There are three SACs with marine components on the west coast of Anglesey relevant to benthic ecology, and one offshore SAC. The MDZ is located within one of these, the North Anglesey Marine SAC. This SAC runs from the northern coast of the Isle of Anglesey into the Irish Sea and has been identified as an important area for harbour porpoise. Covering an area of 3,249 km^2, this site spans water depths which range from the Mean Low Water (MLW) level down to 100 m along the western boundary, though much of the site is 50 m or shallower. The North Anglesey Marine SAC overlaps a range of other habitats including coarse and sandy sediments, rock, and mud.

70. The MDZ also sits within the Anglesey Terns SPA, a site which extends around most of the east, north and west coasts of Anglesey, from the mean high water mark out to between 10 km and 20 km from shore. This site is primarily designated to protect the classified population of foraging terns during the breeding season.

71. The distance of these designations and primary reason for their designation are displayed in **Table 9-14.**

Table 9-14 Designated Sites Within the MDZ and Surrounding Area (up to 100 km)

Site Name	Designation	Distance from Project (km)	Site Features
North Anglesey Marine/ Gogledd Môn Forol	SAC	0	North Anglesey Marine SAC has been identified as an area of importance for harbour porpoise. North Anglesey Marine SAC overlaps a range of other habitats including coarse and sandy sediments, rock, and mud. Encompassed within the site is the Croker Carbonate Slabs SCI which was designated for submarine structures made by leaking gases.
Bae Cemlyn/ Cemlyn Bay	SAC	13.98	Coastal lagoons; Perennial vegetation of stony banks.
Glannau Môn: Cors heli/ Anglesey Coast: Saltmarsh	SAC	16.84	Annex I habitats are the primary reason for selection of this site such as Salicornia and other annuals colonizing mud and sand, and Atlantic salt meadows.
Y Fenai a Bae Conwy/ Menai Strait and Conwy Bay	SAC	27.76	The site is designated for Annex I habitats such as sandbanks which are slightly covered by seawater all the time; mudflats and sandflats not covered by seawater at low tide; and limestone reefs.
Croker Carbonate Slabs	Site of Community	29.83	This site is characteristic of the habitat ‘submarine structures made by leaking gases’ under the subtype “bubbling reefs”. These

Site Name	Designation	Distance from Project (km)	Site Features
	Importance (SCI)		structures form a complex seabed topography providing a diverse habitat for a range of marine life. In other parts of the site, thin slabs form ‘pavements’, which are often overlain with a thin veneer of mobile sand and gravel
Pen Llyn a`r Sarnau/ Lleyn Peninsula and the Sarnau	SAC	32.22	Annex I habitats: sandbanks which are slightly covered by seawater all the time, estuaries, coastal lagoons, large shallow inlets and bays, reefs. Additional Annex I habitats present - Mudflats and sandflats not covered by seawater at low tide, Salicornia and other annuals colonising mud and sand, Atlantic salt meadows, submerged or partially submerged sea caves. Annex II species, not primary reason for site selection: Bottlenose dolphin, otter and grey seal
West Wales Marine/ Gorllewin Cymru Forol	SAC	33.51	West Wales Marine SAC has been identified as an area of importance for harbour porpoise. The area included within the site covers important summer habitat for harbour porpoise, while part of the site in Cardigan Bay was also identified as important during the winter.
Dee Estuary/ Aber Dyfrdwy	SAC	85.64	Annex I habitats: mudflats and sandflats not covered by seawater at low tide, Salicornia and other annuals colonising mud and sand, Atlantic salt meadows. Additional Annex I habitats present – Estuaries, annual vegetation of drift lines, vegetated sea cliffs of the Atlantic and Baltic Coasts, Embryonic shifting dunes, shifting dunes along the shoreline with *Ammophila arenaria*, fixed coastal dunes with herbaceous vegetation, humid dune slacks. Annex II species; not primary reason for site selection: Sea lamprey, river lamprey and Petal wort.
Shell Flat and Lune Deep	SAC	105.32	Shell Flat is considered to be an excellent example of Annex I sandbank Habitat. In terms of sediment type, the bank comprises a range of mud and sand sediments from silts and clays through to coarse sands. Shell Flat is characterised by its low biodiversity, high biomass and is noted as an important foraging ground for many over wintering bird species.
Morecambe Bay	SAC	124.81	Designated for Annex I habitats: estuaries, mudflats and sandflats not covered by seawater at low tide, large shallow inlets and bays amongst several others.
Anglesey Terns/ Morwenoliaid Ynys Môn	SPA	0	Largest tern colony in Wales (500-900 breeding pairs) of roseate, sandwich, common and arctic. Series of islands about 1km out to sea
Liverpool Bay/ Bae Lerpwl	SPA	28.07	Marine site supports red-throated diver, common scoter and little gull.

Site Name	Designation	Distance from Project (km)	Site Features
Traeth Lafan/ Lavan Sands, Conway Bay	SPA	37.86	Local Nature Reserve; supports wintering waterbirds, especially oystercatchers and great crested grebes found here for their autumn moult.
Irish Sea Front	SPA	35.51	The site regularly supports a population of European importance for Manx shearwater (*Puffinus puffinus*), which are likely to use the area as a foraging location during the breeding season. The Irish Sea Front SPA is the third largest marine aggregation of breeding Manx shearwaters identified in the UK.
Northern Cardigan Bay/ Gogledd Bae Ceredigion	SPA	47.97	Qualify as a SPA for its wintering population of red throated diver. Although this is a proposed new SPA, most of the site lies within the existing Pen Llŷn a'r Sarnau Special Area of Conservation.

72. A shadow Habitats Regulations Assessment (HRA) has been compiled to inform the assessment as to whether the Project has the potential to have an adverse effect on the integrity and features of a Natura 2000 site. In summary however, no adverse effects on integrity of any European designated sites are predicted by the Project. Information to support the HRA is provided in **Document MOR/RHDHV/DOC/0067**.

9.5.7. Protected Habitats and Species

73. Within the Ocean Ecology (2018) survey report (**Appendix 9.1, Volume III**), the presence of several habitats of conservation importance in the wider survey area were recorded, including the three Annex I reef habitats: bedrock reef, biogenic reef and stony reef. All of these reefs are extremely variable, both in structure and in the communities they support. These range from vertical rock walls to horizontal ledges, sloping or flat bed rock, broken rock, boulder fields, and aggregations of cobbles. These three reef habitats are afforded protection under the Habitats Regulations.

74. In the UK, the main species that form biogenic reefs are blue mussel *Mytilus edulis*, horse mussel *Modiolus modiolus*, Ross worm *Sabellaria spinulosa*, honeycomb worm *Sabellaria alveolata*, the serpulid worm *Serpula vermicularis*, and cold-water corals such as *Lophelia pertusa*. As noted within the MDZ, the relatively common tube-dwelling polychaete Ross worm *S. spinulosa* was recorded in the surveys conducted by OEL.

75. *S. spinulosa* can form areas of biogenic reef which are highly varied in nature and include reefs which stand up to 30cm high of the surrounding seabed and can extend for hundreds of metres. When considering the potential of an area to qualify as possible *S. spinulosa* reef, several criteria are required to be used to assess the given area of interest. These include elevation, area and patchiness (**Table 9-15**).

Table 9-15 Criteria for Determining *Sabellaria spinulosa* Reefiness (Gubbay, 2007)

Measure of Reefiness	Not classed as a reef	Low	Medium	High
Area (m^2)	<25	25-10,000	10,000-1,000,000	>1,000,000
Elevation (tube height in cm)	<2	2-5	5-10	>10
Patchiness (% cover)	<10	10-20	20-30	>30

76. Within the survey conducted by OEL, (2018), biogenic reefs were observed across 16 stations, (1, 2, 3, 4, 5, 6, 8, 9, 16, 17, 21, 22, 23, 24, 33, 36: Appendix XI of Ocean Ecology Limited (2018)). The quality of the reefs and the levels of 'reefiness' varied between these sample stations, however typically present in 'low' to 'medium' levels of reefiness. The stills of several of these recorded reefs are presented within Appendix XI of the OEL 2018 survey report (Ocean Ecology Limited, 2018).

77. Bedrock and stony reefs are both types of rocky reef which occur where the bedrock or stable boulders and cobbles arise from the surrounding seabed. A stony reef is defined as an area which is comprised of coarse sediments with a diameter of greater than 64 mm (cobbles and boulders) that provide a hard substratum. A reef is defined as having relief from the seafloor and elevation is used as a criterion in its classification. Epifaunal communities of a potential reef are also key in the determination of reefiness, with percentage cover of fauna used as a determination criterion. Irving (2009) classification of reef requires an area of potential stony reef habitat to be greater than 25 m^2 to be classified as a reef.

78. Unlike biogenic and stony reefs, there is currently no specific criteria defined to determine if an area constitutes Annex I bedrock reef. Within the EU directives interpretation, a bedrock reef is defined as:

"*Reef can be either biogenic concretions or of geogenic origin. They are hard compact substrata on solid and soft bottoms, which arise from the sea floor in the sublittoral and littoral zone. Reefs may support a zonation of benthic communities of algae and animal species as well as concretions and corallogenic concretions*."

79. These bedrock reefs create a habitat that is colonised by many different marine animals and plants to many species such as corals, sponges and sea squirts as well as giving shelter to fish and crustaceans such as lobsters and crabs. Rocky reefs can be very variable in terms of both their structure and the communities that they support.

80. Within the surveys conducted for the MDZ, extensive areas of both stony reef and bedrock reef were recorded. The north east spreading along the eastern central area of the site to the south west of the MDZ were dominated by stony reefs, while the central and north east area of the site were recorded as bedrock reef areas. Within the south east of the site, there were several areas of patchy bedrock reef observed, and likewise in the southwest there were areas of patch stony reefs. Within the intertidal zone, the immediate seabed is covered by an expanse of bedrock reef, tailing into stony/bedrock reef in the north east and south east of the site.

9.5.8. Invasive Non-Native Species

81. Invasive Non-Native Species (INNS) are species that have been introduced, either intentionally or unintentionally, to areas outside their natural range. Although many of these non-native species cause no apparent adverse impact, some cause negative impacts on native species and ecosystems due to competition and gradual replacement. There are over forty non-native species reported to occur within Welsh waters (Marine Evidence Working Group, CCW (2012)), seven of which are considered invasive with negative effects, these are:

- *Elminius modestus* – an Australasian intertidal barnacle;
- *Eriocheir sinensis* – Chinese mitten crab;
- *Botrylloides violaceus* – a colonial ascidian native to north-west Pacific;
- *Crassostrea gigas* – Pacific oyster;
- *Crepidula fornicata* – American slipper limpet;
- *Didemnum vexillum* – colonial ascidian commonly known as the carpet sea squirt; and
- *Sargassum muticum* – wireweed/japweed.

82. Further, Anglesey is considered a focal point for INNS due to a high number of hotspots around its coast, including Holy Island and the Menai Strait. The colonial ascidian *Didemnum vexillum*, was recorded in Holyhead Port in September 2008, representing the first confirmed record of the species on the British mainland (Griffith et al., 2009). This is a great concern for both Welsh waters and the waters of the UK due to its ability to successful invade and establish.

9.6. IMPACT ASSESSMENT

83. The following assessment provides a summary of all impacts identified during scoping study and those which have been noted as the EIA has progressed. Each impact is not necessarily relevant to all stages of the project, and thus impacts have been assessed within the stage of the project at which they will occur (construction, operation and decommissioning). Further, these impacts are comprised of both direct and indirect impacts.

84. Impacts are classified as follows:

- Direct impacts: these may arise from impacts associated with the construction, operation and maintenance, or decommissioning of the project;
- Indirect impacts: these may be experienced by a receptor that is removed (e.g. in space or time) from the direct impact;
- Inter-relationships between impacts; or Cumulative impacts: these may occur as a result of the project in conjunction with other existing or planned projects within the study area for each receptor.

9.6.1. Embedded Mitigation

85. The following assessment provides a summary of all impacts identified during scoping study and those which have been noted as the EIA has progressed. These impacts are not relevant to all stages of the project, and thus impacts have been assessed within the stage of the project at

which they will occur (construction, operation and decommissioning). Further, these impacts are comprised of both direct and indirect impacts.

86. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process (see **Chapter 4, Project Description** for further details). A range of different information sources has been considered as part of embedding mitigation into the design of the project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

9.6.1. Worst Case Parameters

9.6.1.1. Temporary Habitat Disturbance

87. During all project phases, temporary habitat disturbance will occur to seabed habitats via device, hubs and cable installation and also anchor deployments for installation barges. Based on information provided in **Chapter 4, Project Description**, the values in **Table 9-16** have been calculated to define the worst-case parameters for temporary habitat disturbance . These are defined in terms of project phase, as different amounts of temporary seabed disturbance are predicted to arise in each phase.

88. For the purpose of defining impact assessment parameters for the repowering phase, an assumption has been made that 50 % of the tenants will undertake repowering, i.e. for 50 % of the tenants, their infrastructure will be removed and replaced (potentially with different infrastructure by a different tenant). For the other 50 % of tenants, their infrastructure will remain over the lifetime of the Project.

89. In terms of impact assessment parameters, the repowering process has, therefore, been defined as per below:

- Initial temporary seabed disturbance via deployment of barge anchors to remove foundations, TEC’s, hubs, inter-array cables and monitoring equipment for 50 % of the Tenants (berths);
- Further temporary seabed disturbance via re-installation (repowering) of foundations, TEC’s, hubs, inter-array cables and monitoring equipment for the same 50 % of Tenants (berths); and
- Additional permanent habitat loss (over and above that via initial construction phase), due to placement of re-installed (repowered) foundations/TECs in different areas to where originally installed.

90. The operational phase values also include the temporary seabed disturbance that would arise from up to ten cable repair events.

Table 9-16 Summary of Worse-Case Scenario Temporary Habitat Loss during Construction, Operation (repowering) and Decommissioning Phases

Project Component	Worse Case (240 MW)	Unit	Notes
Construction Phase:			
Post-lay burial of cable	27,259	m^2	Area of sandwave field where post-lay burial via Mass-Flow Excavator (MFE) may be required
Deployment of anchor blocks by barges during cable installation	100,240	m^2	Up to 8 x 25 m^2 (5x5) m anchor blocks for a single barge = a total footprint per anchor deployment of 200 m^2 (8 x 25 m^2) Assumed that these types of anchor barges generally deploy a spread every 500 m. So, for every 500 m of cable installation a footprint of 200 m^2 of temporary seabed disturbance occurs (via the anchor blocks) Combining all potential export, array and cable tails the total length of cables (full 240 MW) is 250.6 km Assumes the footprint of 200 m^2 every 500 m (0.5 km), or 400 m^2 every 1 km, and assumes all cables are installed using anchor barges Temporary disturbance impact of (400 m^2 x 250.6) = 100,240 m^2 (0.10 km^2)
Deployment of anchor blocks by barges during TEC device installation	248,000	m^2	Max. no of devices set at 620 x small (0.3 kW devices) Assumed that deployment of each device requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2) Therefore, total temporary seabed disturbance = 620 x 400 m^2 = 248,000 m^2
Deployment of anchor blocks by barges during hub installation	48,000	m^2	Max. no of seabed mounted hubs set at n = 120 Assumed that deployment of each hub requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2) Therefore, total temp. seabed disturbance = 120 x 400 m^2 = 48,000 m^2
Construction Phase TOTAL		**423,499 m^2 (0.42 km^2)**	
Operational Phase:			
(Repowering) 50 % of tenants infrastructure (Foundations; TEC's; hubs' array cables; monitoring equipment) removed and replaced with new	377,400	m^2	Initial <u>removal</u> of tenant infrastructure from 50 % of berths ▪ 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 ▪ 50 % of anchor block value of tidal device installation = 124,000 m^2 ▪ 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2

Project Component	Worse Case (240 MW)	Unit	Notes
(different) tenant infrastructure			Subsequent re-installation (re-powering) of tenant infrastructure from 50 % of berths ▪ 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 ▪ 50 % of anchor block value of tidal device installation = 124,000 m^2 ▪ 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2
Cable repairs	3,000	m^2	Up to 10 major cable repairs (5 days each) may be required throughout the project life. It is assumed that up to 750 m of cable will be subject to repair works per event (7,500 m in total). Using same value of 400 m^2 temp seabed disturbance per 1 km of cable works (400 x 7.5) = 3,000 m^2
Operational Phase TOTAL		**380,400 m^2 (0.38 km^2)**	
Decommissioning Phase:			
Decommissioning Phase		**TOTAL 423,499 m^2 (0.42 km^2) –** same worst-case as per construction phase due to same activities needed to remove infrastructure	

91. The installation of project infrastructure, including anchor systems for TEC devices, seabed mounted devices, hubs and cables/cable protection, will all result in permanent habitat loss. Based on information provided in **Chapter 4, Project Description**, the following values have been calculated to define the worst-case parameters for permanent habitat loss via project infrastructure (**Table 9-17**). The majority of these effects will only occur in the operational phase. The exception is the value of 7,400 m^2 related to the trench for up to nine cables at landfall. Trenching of cables will only be undertaken if HDD works (preferred method) are not possible/viable. Without detailed geotechnical analysis it is not currently possible to state if trenching, and subsequent backfill of the trench(es) would be possible. If it was, this would represent a temporary disturbance on intertidal habitats. However, to ensure a precautionary approach, it has been concluded that trenching/surface-laying of the landfall cables would lead to permanent habitat loss and is included below.

Table 9-17 Summary of worse-case scenario: permanent habitat loss via project infrastructure (including repowering)

Project Component	Worse Case (240 MW)	Unit	Notes
Main operational phase			
Gravity Base Structures (GBS)	74,790	m^2	Max value across entire project. Based on anchor mooring systems for floating devices. Includes hubs.
Swept Area of Catenary Cables	2,055,000	m^2	Based on: 30 devices having swept area of 9,500 m^2 (large floating devices (Orbital, Magallanes)

Project Component	Worse Case (240 MW)	Unit	Notes
			140 devices having swept area of 7,500 m^2 floating devices (Tocardo UFS, Aquantis) & hubs 240 devices having swept area of 3,000 m^2 small floating devices (Instream, SME PLATO)
Export Cable Footprint (cables; protection systems; rock bags)	11,745	m^2	Up to 40.5 km of export cables (with split-pipe protection/shells and rock bags)
Array Cable Footprint (cables; protection system; rock bagss)	30,040	m^2	Up to 204.5 km of array cables (with split-pipe protection/shells and rock bags)
Cable tails	120	m^2	Based on 9 x tails of 620 m length
Trench for 9 x landfall cables	7,400	m^2	740 m long trench x 10 m width
Footprint of Navigation Marker Buoys	540	m^2	3 m diameter square gravity anchor (9 m^2) per anchor x 60 anchors/buoys
Footprint of ADCP moorings	280	m^2	7 m^2 per ADCP mooring x 40 units
Footprint of seabed mounted environmental monitoring units	112	m^2	14 m^2 per env monitoring unit x 8 units
Footprint of mooring for floating environmental monitoring units	45	m^2	9 m^2 per mooring x 5 units
Permanent habitat loss (initial operational phase: 2,180,072 m^2 (2.18 km^2)			
Repowering Phase			
New tenant infrastructure in 50 % of berths	52,504	m^2	
Permanent habitat loss (repowering of 50 % of berths): 52,504 m^2			
Permanent Habitat Loss: Total of 2,232,576 m^2 (2.23 km^2)			

9.6.1.2. Construction Programme

92. The construction of offshore works (for installation of tidal devices and associated cabling and infrastructure) would be phased over a period of several years, taking: up to 15 days per device or hub; and up to 1.5 days for each inter-array cable; up to 20 days for each offshore cable; and up to 12 days for each phase of cable protection. Up to eight separate cable laying and protection campaigns are possible. The HDD at the landfall would be completed over a 10 month period with 2 months for offshore cable tail installation.

9.6.2. Potential Impacts during Construction

9.6.2.1. Construction Impact 1: Physical Disturbance to Benthic Habitats and Species and Temporary Habitat Disturbance

93. Throughout the various stages of construction, there will be possible disturbance and temporary habitat loss to benthic species within the MDZ. Under the worst-case scenario, an area of up to 423,499 m^2 (0.42 km^2) would be temporarily disturbed due to construction associated activities

such as post-lay burial of cable through the large sandwave feature present in the site and installation of an anchor barge to allow for device installation.

94. The proposed total area of the MDZ and export cable corridor (ECC) is 39.75 km^2, comprised of 35 km^2 within the offshore development site, an ECC area of 4.75 km^2, of which 0.01 km^2 falls within the intertidal region (MLWS to MHWS). Therefore, given that the worst-case construction scenario, seabed footprint of the project could result in the temporary loss of up to 423,499 m^2, a worst-case scenario design would result in the temporary disturbance of a 1.06 % of the seabed within the MDZ and ECC.

95. Based on the biotope mapping conducted by OEL (Ocean Ecology, 2018), the site is covered by a high percentage of the biotopes CR.HCR.FaT, CR.HCR.XFa, CR.MCR.CSab and SS.SCS.CCS. Following the process of assigning each biotope to a VER group, habitat group 9 (High energy infralittoral and circalittoral rock/ coarse sediment with Annex I stony/bedrock reef) and 10 (Circalittoral Sabellaria reefs – Annex I biogenic reefs) were the most frequently occurring groups in the subtidal region. These groups contain possible Annex I reef habitats (biogenic, bedrock and stony). In the OEL survey report, observations of Annex I stony reef habitat (as per Irving 2009) frequently overlain by varying coverage of *S. spinulosa* tube aggregations (representative of Annex I biogenic reef were observed in deeper areas of the survey site (as per Gubbay 2007)). The amount of overlying sediment was reduced in the slightly shallower waters in central, southern and northern areas where tide-swept and mixed faunal turf community representative of Annex I bedrock reef were prevalent. Within this assessment of temporary habitat loss, VER habitat group 9 and VER habitat group 10 have been assessed.

96. Given the high percentage coverage of similar habitat types available within the MDZ and the low level of overall temporary habitat disturbance or loss that will occur in the construction phase, this impact is of a scale which would be barely noticeable from monitoring and would occur only occasionally. Therefore, the magnitude of this effect has been assessed as low.

97. Habitat group 10 represents the group which contains possible areas of biogenic Annex I reef (*Sabellaria* spp.). Within the MarLIN assessment for abrasion and disturbance assessment, this habitat is assessed with a medium sensitivity, as abrasion at the surface of *S. spinulosa* reefs is considered likely to damage the tubes and result in sub-lethal and lethal damage to the worms. However, it should be noted that this assessment was suggested as relatively precautionary and it should be noted the degree of resilience will be mediated by the character of the impact. The recovery of small areas of surficial damage in thick reefs is likely to occur through tube repair and may be relatively rapid.

98. Considering the current knowledge of *S. spinulosa* reef ecology it is evident that such habitat follows a cycle of evolution and degradation within periods of months (evolution of functioning reefs has been recorded within a 6-month period) and demonstrates a high degree of recoverability following direct impacts (Pearce et al., 2007; Hendrick et al., 2011; Last et al., 2011).Therefore, it is unlikely that if any reef is impacted, that the consequent direct impacts will be long-lived i.e. the reef habitat demonstrates a high recoverability.

99. Based on advice provided by Natural England (Advice on Operations) for The Wash and North Norfolk Coast SAC (as this site contains Annex I stony reef), stony reefs are associated with a medium sensitivity in relation to cable laying activities. Within this assessment, no assessments

on sensitivity were available for bedrock and a low sensitivity has been concluded. An overall medium sensitivity has been assessed for VER habitat group 9 and VER habitat group 10.

100. As the VERs have been assessed with an overall medium sensitivity and the magnitude of the impact is low, physical disturbance and overall temporary disturbance of subtidal habitats is likely to result in a **minor adverse** impact.

9.6.2.1.1. Mitigation

101. Topic-specific mitigation will be conducted to ensure minimal disturbance and loss of habitats and species during construction. Following consent, pre-construction surveys could be carried out to check for the presence of any rare or protected habitats and species e.g. *S. spinulos*a reefs. Following these surveys, micro-siting of the cable would be used to mitigate impacts to these receptors where possible.

9.6.2.1.2. Residual Impact

102. The impact will remain of minor adverse significance (**Table 9-18**).

Table 9-18 Summary of Construction Impact 1: Physical Disturbance to Benthic Habitats and Species and Temporary Habitat Disturbance

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Construction						
Impact 1: Physical disturbance to habitats and species and temporary habitat loss	VER Group 9 and 10	Medium	Low	Minor Adverse	Mitigation will be conducted to ensure minimal disturbance to and loss of habitats and species during construction via pre-construction surveys and micro-siting.	Minor Adverse

9.6.2.2. Construction Impact 2: Increased Suspended Sediment Concentration and Sediment Deposition

103. The following assessment is supported by the information presented within **Chapter 7, Metocean Conditions and Coastal Processes**.

104. Throughout the construction phase there is potential for foundation installation activities within the Project to disturb sediments, either from the seabed surface or from below the seabed (depending on foundation type). This disturbance can release sediment into the water column as a plume which may then be deposited within or around the MDZ. Suspended sediment concentrations can increase in the water column, making it more turbid, until the plume becomes

dispersed by tidal current action and the sediments settle once again on the sea bed. This could then interact with the subtidal environment and cause smothering of sensitive sessile species.

105. The principal causes of disturbance during foundation installation would be:

- The preparatory works for foundation installation, including boulder clearance;
- Placement of bed-mounted gravity base foundations on the sea bed;
- Installation of anchor points for floating systems;
- Pre-drilling of rock sockets for piled foundations (e.g. monopiles or pin piles); and
- Cable post-lay burial.

106. Within the MDZ there is a paucity of surface sediment, with tide-swept bedrock prevailing. Where sediment does exist in these areas, it is sparse, and predominantly gravel, cobbles and rock boulders. These particle sizes are so large that they either cannot be suspended in the water column or will drop from suspension within a few centimetres from location of disturbance. In effect they will not form part of a sediment plume even if disturbed during construction. Therefore, release of sediments from pre-drilling below the sea bed is of greater potential significance. This would be associated with the installation of piled foundation (for hubs) that may be required for the Project and has been considered as the worst-case scenario for this impact.

107. In practice, the pre-drilling work required for the hub foundations will progress sequentially over time (rather than being instantaneous). Therefore, the realistic worst-case scenario is sediment release from one foundation location at a time. Under this scenario, any plume that is generated would disperse well before the potential exists for its coalescence with plumes from adjacent (or any other) pre-drill locations.

108. The total volume of sediment released from pre-drilling for hub foundation installation would be extremely small (340 m^3 per foundation, as discussed within **Chapter 7, Metocean Conditions and Coastal Processes**), likely to result in peak increases in suspended sediment concentration of typically less than 10 mg/l within the points of release, rapidly reducing to less than 1 mg/l at only a short distance from each release point. This low (barely measurable) effect is partly due to the low volume of sediment released from drilling at the location of each release point; and partly because any fine material released would be rapidly dispersed by the strong tidal currents along the axis of tidal flow.

109. The maximum envisaged effect associated with sediment plumes arising from the foundation installation activities will cause only very minor enhancements in suspended sediment concentration (typically less than 1 mg/l a short distance from the release point) over only a small geographical area (a few hundred metres). This very minor enhancement of suspended sediment concentration over a small geographic area (typically less than 1 mg/l within short distances from release point) would be temporary and return to very low background concentrations rapidly upon cessation of the construction activity.

110. Any sediment that becomes entrained within the plume generated by foundation installation will have the potential to deposit on the sea bed at some distance from its point of release. Based upon a realistic worst case of sediment release from a single piling activity at a time, the sediment deposition on the sea bed will be extremely small in thickness. It is envisaged that in the

immediate vicinity of the release point, deposition depths of no more than 0.1 m will be observed. These sediments are then highly likely to become re-entrained by currents during the peak velocities of the following tide and transported further away in small concentrations.

111. MFE/jetting will be employed to bury the cable across any sandwave features. As part of this process the sediment will be mobilised, creating a very localised sediment plume that re-settle 10-100 metres from the source of jetting and will remain in the system.

112. Therefore, based on the assessments presented in **Chapter 7, Metocean Conditions and Coastal Processes**, changes in the suspended sediment concentration and sediment deposition arising from the construction phase of the Project would be negligible and a **negligible** magnitude has been assessed.

113. The ‘light smothering and siltation rate changes’ and ‘changes in suspended solids’ MarLIN pressures were used to inform this assessment. It is noted that the impacts of increased suspended sediment concentrations and deposition on benthic and epibenthic communities will vary greatly in relation to species present. Filter feeders are likely to be more sensitive to potential adverse effects, whereas deposit feeders may benefit from a sediment influx. Within this assessment, the sensitivity assessment was conducted against the VER habitat group 10 (Circalittoral *Sabellaria* reefs – Annex I biogenic reefs) due to its designation as an Annex I habitat and high coverage of the MDZ.

114. Due to the natural ecology of *Sabellaria* spp., there is a reliance on a supply of suspended solids and organic matter in order to filter feed and build protective tubes and so they are often found in areas with high levels of turbidity. Studies such as Davies, et al. (2009) have shown that at high and intermediate sediment regimes (~71 mg/l) *S. spinulosa* maintained a cumulative growth rate. This supports the view that availability of suspended particles is necessary for *S. spinulosa* development and that tolerance of elevated levels is likely (Davies et al., 2009). Further, studies have provided evidence which indicate that *S. spinulosa* can survive short-term (32 days), periodic sand burial of up to 7 cm (Last et al., 2011). Within the MDZ, it is expected that suspended sediment concentration will rise to less than 10mg/l within the points of release, rapidly reducing to less than 1 mg/l at only a short distance from each release point. Likewise, it is envisaged that in the immediate vicinity of the release point, deposition depths of no more than 0.1 m will be observed and will be rapidly reduced following a tidal flow over the area.

115. Sediment deposition in association with cable lay post-burial activity will be restricted to the footprint of the sandwave features. The benthos associated with these features are adapted to living within sediments and are not sensitive to deposition of sediments and smothering effects.

116. Therefore, it is unlikely that there will be impacts to this VER group or other benthic groups, and a low sensitivity has been assessed for increased sediment plumes and deposition. As the magnitude of effect is deemed to be negligible and the sensitivity as low, an overall **negligible** impact is predicted.

9.6.2.2.1. Mitigation

117. As the impact assessment for potential increased suspended sediments and smothering is **negligible**, no specific mitigation is proposed.

9.6.2.2.2. Residual Impact

118. As no mitigation is proposed, the impact will remain of **negligible** significance (**Table 9-19**).

Table 9-19 Summary of Construction Impact 2: Increased Suspended Sediment Concentration and Sediment Deposition

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Construction						
Impact 2: Increased suspended sediment concentration and sediment deposition	VER Group 10	Low	Negligible	Negligible	None required	Negligible

9.6.2.3. Construction Impact 3: Release of Pollutants Due to Accidental Events

119. Although the probability of an oil spill occurring within the MDZ during construction is deemed to be negligible, the impacts of such an event are assessed further.

120. Within all project phases, there is the risk of potential accidental release of pollutant discharges from the hydrocarbon inventories carried by installation and maintenance vessels, and other harmful substances. This accidental spill may occur due to poor weather, collision or equipment failure. The exact worse-case scenario of potential pollutants is not possible to calculate as vessels have not been planned for works, however an estimate of a total of up to 444,000 litres of oils for gearboxes and transformers; grease for bearings and seals, and hydraulic fluid has been assigned for this assessment (based on 240 x 1 MW drivetrains).

121. Marine pollution would be restricted to matters related to leakage of lubricants and the type of paint or coating that the subsurface structures would use to prevent excessive growth of marine organisms. Any leak is not likely to result in the discharge of more than 1,000 litres of oil based hydraulic fluid. Discharges from installation and O&M vessels may occur (such as cooling water) however, this will be restricted by maritime standards and regulations.

122. Therefore, given that the possibility of an oil spill is very low and would result in a temporary change, the likelihood and therefore magnitude of this event occurring have been assessed as low.

123. Spilled oils have the potential to affect the subtidal and intertidal benthic ecology in numerous ways, from suffocation, poisoning, bioaccumulation, modification of habitats and other indirect routes. An environments sensitivity to oil pollution varies greatly between habitats and species, and is also linked to sediment types, substrates and the exposure of an area. Given that the Project being developed is a tidal energy demonstration zone, the MDZ is a very exposed area with a high tidal energy range. This highly energetic environment will therefore react in a less sensitive way to an oil spill than would an environment comprised of low energy soft sediments.

124. The rocky and hard substrates observed within and around the MDZ are less sensitive to oil spills (than sediment systems), and these hard substrates aid in the breaking up of oils into smaller droplets thereby increasing surface area and increasing biodegradation rates. However, the coasts around Anglesey are varied and several types of habitat and sediment types could be impacted. This coupled with the generally high sensitivity benthic receptors display in relation to oil spills has concluded a high sensitivity to this impact.

125. Based on a low magnitude score due to the very unlikely possibility of such an event occurring, and the high sensitivity of the impact of this event, an overall **moderate adverse impact** is predicted.

9.6.2.3.1. Mitigation

126. To minimise the risk of a pollution event occurring within the MDZ, several mitigation measures will be implemented as part of the project embedded mitigation (**Chapter 4, Project Description**):

- Development of an Emergency Response Cooperation Plan (ERCoP) with guidance set out by MCA in MGN 371, issued and approved by MCA;
- Development of a Marine Pollution Contingency Plan and Vessel Management Plan, which would include the following measures:
  - Notice to Mariners to be issued to reduce collision risks;
  - Vessels associated with all Project operations will comply with IMO/MCA codes for prevention of oil pollution and any vessels over 400 GT will have on board SOPEPs;
  - Vessels associated with all Project operations will carry on-board oil and chemical spill mop up kits; and
  - Where possible, vessels will avoid working in poor weather conditions.

9.6.2.3.2. Residual Impact

127. Given the suggested mitigation to reduce and lessen risk due to guidance and mitigation plans, the impact will be reduced but will remain of **minor adverse** significance (**Table 9-20**).

Table 9-20 Summary of Construction Impact 3: Pollution of Water and Sediment through Accidental Events

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Construction

Construction						
					Contingency Plan and Vessel Management Plan ▪ Notice to Mariners; ▪ Compliance with IMO/MCA codes/ on board SOPEPs; ▪ On-board oil and chemical spill mop up kits; and ▪ Where possible, avoid working in poor weather conditions.	

9.6.2.4. Construction Impact 4: Physical Disturbance to Intertidal Habitats and Species during Landfall Works

128. As described above, the worst-case scenario for benthic and intertidal impacts at landfall would be as a result of the export cables being installed in a cut trench. This would result in the temporary disturbance of all sessile species and habitats within up to 7,400 m^2 to the trench for up to nine cables at landfall in the intertidal and near shore subtidal zones.

129. Trenching of cables will only be undertaken if HDD works (preferred method) are not possible/viable. Without detailed geotechnical analysis it is not currently possible to state if trenching, and subsequent backfill of the trench(es) would be possible. If it was, this would represent a temporary disturbance on intertidal habitats.

130. Within the surveys conducted to support this assessment, an intertidal survey was conducted and the habitat across the area described as supporting a wide variety of littoral rock biotopes representative of Annex I bedrock reef interspersed with discrete patches of barren shingle and occasional areas of sandy sediment.

131. Following the biotope mapping and assignment of VER groups, VER habitat group 1 (high energy littoral rock) and habitat group 12 (yellow and grey lichens on supralittoral rock) were observed to dominate the intertidal area of the MDZ. However, group 9 (High energy infralittoral and circalittoral rock/ coarse sediment with Annex I stony/bedrock reef) has been used as the

receptor in the assessment as several areas of this habitat were observed in the intertidal site, and this is the most valued group containing habitats which are designated as Annex I habitat.

132. The intertidal area of the MDZ equates to 10,000 m^2 and the temporary disturbance of 7,400 m^2 equates to 74 % of the MDZ intertidal area. Although a very high percentage of temporary disturbance, a medium magnitude has been applied. This is due to the scale of the impact, which will cause a change which will be noticeable from monitoring, and due to the reversibility of the effect.

133. Due to the exposed nature of the offshore site to wave regimes, habitats and species of the intertidal are not likely to be sensitive to disturbance and therefore a medium sensitivity is considered appropriate for this impact despite the possible presence of Annex I bedrock reef due to the possible level of temporary disturbance that may occur. Therefore, given that a medium magnitude and a medium sensitivity have been assigned, an overall **moderate adverse** impact is predicted via temporary disturbance to the intertidal zone due to temporary habitat loss.

9.6.2.4.1. Mitigation

134. If it is not possible to conduct cable-lay via the preferred HDD method, then prior to the excavation of the trench and installation of the cables, a detailed installation methodology would be produced. This will outline how the substratum will be reinstated with the right stratification of layers and will describe how physical impacts will be kept to a minimum, for example restricted working corridors for vehicles and personnel. Larger boulders would be moved sideways out of the cable trench corridor to an equivalent area of the shore, prior to trenching work commencing. These boulders would then be used as the upper layer after backfilling the trench.

9.6.2.4.2. Residual Impact

135. Given the suggested mitigation to reduce and lessen the impact on the intertidal area from cable laying, the impact will be reduced to **minor adverse** (**Table 9-21**).

Table 9-21 Summary of Construction Impact 4: Physical Disturbance to Intertidal Habitats and Species During Landfall Works

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Construction						
Impact 4: Physical disturbance to intertidal habitats and species during landfall works	VER Group 1, 9, 12	Medium	Medium	Moderate	Agree work method with NRW to minimise disturbance.	Minor adverse

9.6.2.5. Construction Impact 5: Potential Introduction/Spread of Invasive Non-Native Species

136. During the construction stages of the MDZ, there is the potential for the introduction and spread of invasive non-native species (INNS), particularly as Anglesey is considered a focal point for INNS due to a high number of hotspots around its coast. The colonial ascidian *Didemnum vexillum*, was recorded in Holyhead Port in September 2008, representing the first confirmed record of the species on the British mainland. This record sparked concern due to the potential vigorous growth which could occur in both artificial aquaculture facilities and in the natural environment.

137. There are several mechanisms by which vessels associated with the project may introduce INNS to waters within and around the MDZ:

- Attached to equipment such as anchors/anchor chains;
- Fouling on hulls;
- Seawater in pipework; and
- Ballast water and within sediment within ballast tanks.

138. Introductions may present themselves from vessels from foreign waters, and from within Wales. Therefore, there is the potential for the introduction of both new INNS and an increased range for those which are established within the marine environment within Wales.

139. Given the complex interaction between the introduction of a non-native species into an environment and establishment within the MDZ or Wales, the magnitude of the impact has been assessed with caution as medium.

140. Based on the above, the introduction/spread of invasive non-native species within the MDZ and around Anglesey is plausible, however it is unlikely that this will lead to alterations in the benthic habitats or communities due to the current high level of hard substrate naturally available. Therefore, the project associated infrastructure does not present a novel environment within the MDZ, as it would if it was to be placed within a soft sediment area. It is therefore unlikely that the level of risk associate with the new infrastructure and/or the project construction activities will lead to significantly greater levels of INNS.

141. Given the current possible risk held by the receptor (the benthic habitats within the MDZ), the sensitivity has been assessed as medium**.** Overall, a **moderate adverse impact** is predicted via he potential introduction/spread of INNS.

9.6.2.5.1. Mitigation

142. Project embedded mitigation measures are proposed to minimise the risk of INNS and their successful invasion within the MDZ and wider region (**Chapter 4, Project Description**), including compliance with relevant guidance regarding ballast water and INNS risk assessment prior to each deployment to identify mechanisms behind risk identified and appropriate mitigation measures. This can be undertaken once installation vessels and construction / manufacturing ports have been identified through maintenance of an Invasive Species and Biosecurity

Management Plan (ISBMP). An outline INNS Management Plan has been provided with this application (**Document MOR/RHDHV/DOC/0075, INNS Management Plan**).

9.6.2.5.2. Residual Impact

143. If the above mitigation is followed and measures put in place to assess the possible likelihood of INNS invasion based on project vessels, the likelihood of introducing INNS to the MDZ and wider area will be reduced to and re-assessed to **minor adverse** significance (**Table 9-22**).

Table 9-22 Summary of Construction Impact 5: Potential Spread of Non-Native

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Construction						
Impact 5: Potential spread of non-native	Benthic habitats within MDZ	Medium	Medium	Moderate	Compliance with guidelines, risk assessment of project vessels for INNS and further mitigation measures if required.	Minor Adverse

9.6.3. Potential Impacts during Operation

9.6.3.1. Operational Impact 1: Long Term Loss of Benthic Habitat via (a) Initial Placement of Project Infrastructure and (b) Repowering

144. Due to the initial placement of project infrastructure directly on the seabed, a direct long-term habitat loss will occur for the duration of the operation phase of the Project. In addition to that initial impact, repowering of up to 50 % of the berths may take place. Repowering is defined in **Chapter 4, Project Description** as being ‘the removal of a tenant’s infrastructure at the end of a demonstration period and replacement with the infrastructure of a new tenant, including the removal of devices (including foundations, TECs, support/super structure, inter-array cables, hubs and monitoring equipment) and reinstallation via the original construction methods. For the purpose of this assessment it has been assumed that any new (repowered) infrastructure would be deployed in a new area, i.e. an additional loss of habitat.

145. Under the worst-case scenario, an area of up to 2,180,072 m^2 (2.18 km^2) of seabed would be lost due to the initial placement of project infrastructure. This includes a maximum design and worst case scenario of a loss of a possible 2,055,000 m^2 due to the swept area of the catenary cables, based on 30 devices with a swept area of 9,500 m^2 each, 140 devices with a 7,500 m^2 swept area and 240 devices with a 3,000 m^2 swept area.

146. As a result of repowering, an additional 52,504 m^2 of permanent habitat loss would occur (although it should be recognised that in areas where original infrastructure has been removed, these seabed habitats will no longer be "lost" and will begin a process of recovery). Therefore, the combined permanent habitat loss from initial installation and then repowering amounts to 2,232,576 m^2 (2.23 km^2).

147. The proposed total area of the MDZ and export cable corridor (ECC) is 39.75 km^2, comprised of 35 km^2 within the offshore development site, and an ECC area of 4.75 km^2, of which an intertidal region (MLWS to MHWS) is 0.01 km^2. Therefore, given that the worst-case scenario seabed footprint for a maximum design of the MDZ within the construction period of the project could result in the loss of up to 2,232,576 m^2, a worst-case scenario design would result in the loss of a 5.61 % of the seabed within the MDZ and ECC area.

148. The subtidal area of the MDZ is dominated by the biotopes CR.HCR.FaT, CR.HCR.XFa, CR.MCR.CSab and SS.SCS.CCS which fall within the Valued Ecological Receptors habitat group 9 (High energy infralittoral and circalittoral rock/ coarse sediment with Annex I stony/bedrock reef) and 10 (Circalittoral Sabellaria reefs – Annex I biogenic reefs), while the intertidal zone is dominated by the VER habitat group 1 (high energy littoral rock) and habitat group 12 (yellow and grey lichens on supralittoral rock).

149. It has not been possible to provide an accurate calculation of the loss of each VER due to the current unknown location of devices and therefore VERs which will be impacted. Although there is a high percentage coverage of similar habitat types within the MDZ available, the scale of the change would be noticeable due to an overall habitat loss of 5.61 %. This impact will occur at a scale which would be noticeable from monitoring but would remain within the range of natural variations of background conditions. Further, the effect is slowly reversible following decommissioning (5-10 years) and therefore has a medium level magnitude has been assigned.

150. Based on MarLIN assessments, as discussed within Construction Impact 1, medium sensitivity has been applied to the most sensitive receptors (VER habitat group 9 and 10) and the most frequently occurring within the intertidal zone (VER habitat group 1 and 12).

151. Therefore, as a medium magnitude and a medium sensitivity to the receptors, an overall **moderate adverse** impact is predicted for the permanent loss of habitat due to the placement of infrastructure from the Project.

9.6.3.1.1. Mitigation

152. Given that a moderate significant impact is predicted for the permanent loss of habitat arising from the placement of project infrastructure, topic-specific mitigation will be conducted to ensure minimal loss of habitats and species within the operational phase. Following consent, pre-construction surveys will be carried out to check for the presence of any rare or protected habitats and species, including Annex I habitats which may be classified as reef features. Following these surveys, micro-siting of the cable would be used to mitigate impacts to these receptors where possible. This would inform areas which should be avoided and areas which infrastructure should not be placed.

9.6.3.1.2. Residual Impact

153. The mitigation measures would ensure the minimal possible infrastructure footprint during the operational phase of the project; allow for the impact level to be adjusted to a **minor adverse** impact (**Table 9-23**).

Table 9-23 Summary of Operational Impact 1: Long Term Loss of Benthic Habitat via (a) Initial Placement of Project Infrastructure and (b) Repowering

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Operation and Maintenance						
Impact 1: Long term loss of benthic habitat via placement of project infrastructure	VER Habitat Group 1, 9 and 12	Medium	Medium	Moderate	Following consent, pre-construction surveys and possible micro-siting will be conducted to allow for identification of important areas of habitat.	Minor Adverse

9.6.3.2. Operational Impact 2: Changes in Hydrodynamic and Inter-Related Effects on Benthic Ecology

154. There is the potential of alteration to local hydrodynamics within the MDZ which would link to changes in the sediment type and structure and therefore the benthic species composition. An interaction between tidal driven flows and cylindrical piles or structure creates an array of hydrological phenomena including water flow contractions, 'horse-shoe' vortices and turbulent lee-wake vortices (Hoegald and Hald, 2005). This leads to the net removal of sediments in soft sediment areas, and ultimately the creation of scour pits around the base of the infrastructure. Within the MDZ, there are few areas of soft sediment and the site is dominated by hard substrates. Therefore, it is unlikely that scour pits will develop and thus there is little chance of vast changes to sediment compositions within the area.

155. Due to the small scale of the Project, perceptible changes on the wider water flow regime and sediment compositions, possible impacts to benthic communities would be very small and localised. Coastal process modelling concluded that even within the worst cases of seabed deployment, the magnitude of reduction in tidal current flow (up to 0.8 m/s) results in a residual current flow at high speeds, because the baseline flow conditions in these most affected areas are typically greater than 2 m/s.

156. Subsequently, the near-field magnitude of effect was assessed as low-medium, and the far field effect as negligible.

157. Due to the sensitivities discussed in relation to changes in suspended sediment within **Section 9.6.2.2**) and the naturally exposed nature of the site, a low sensitivity has been assessed for all

benthic receptors in relation to changes in hydrodynamics. Therefore, a **minor adverse** significant impact is predicted.

9.6.3.2.1. Mitigation

158. No mitigation is proposed.

9.6.3.2.2. Residual Impact

159. As no mitigation is proposed, the impact will remain minor adverse (Table 9-24).

Table 9-24 Summary of Operational Impact 2: Changes in Hydrodynamic and Inter-Related Effects on Benthic Ecology

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Operation and Maintenance						
Impact 2: Changes in hydrodynamic and inter-related effects on benthic ecology	Benthic habitats within MDZ	Low	Medium	Minor Adverse	None required	Minor Adverse

9.6.3.3. Operation Impact 3: Introduction of New Habitat in the Form of Project Infrastructure

160. The development of infrastructure within the site presents new surface areas for colonisation by a variety of species, including INNS. This therefore has potential to alter the benthic species and communities in the offshore site.

161. Although it is hard to predict the species that will potentially colonise these structures, they will likely be similar to those that are already within the various biotopes across the MDZ subtidal area, as the hard structures will be similar to the hard bedrock and stony reefs within the area. Therefore, the impacts of introduction of hard substrates into an already largely hard sediment dominated area will not be as significant as the impacts of the introduction of hard substrates into a predominately soft sediment environment.

162. As discussed within the PTEC benthic ecology assessment (PTEC, 2014), monitoring of the impacts of the SeaGEN device within Strangford Lough, Northern Ireland (Royal HaskoningDHV, 2011a) concluded that the colonisation on the infrastructure largely replaced that of which was lost during the installation of the foundations. These results also represent a hard, rocky reef environment, within a high energy environment.

163. Total new surface area of hard substrates from the introduction of hard substrates are not currently available due to the possible variances in the project development. However, the effect would be highly localised around each installed structure and therefore the magnitude of the impacts of the introduced substrate on the existing communities is considered to be negligible.

164. In the absence of sufficient information, a cautionary medium sensitivity of all benthic VER groups has been applied. A negligible magnitude and medium sensitivity have concluded an assessment of **minor adverse impact**.

9.6.3.3.1. Mitigation

165. No mitigation is suggested for this impact.

9.6.3.3.2. Residual Impact

166. As no mitigation is suggested, a **minor adverse** significance remains for this impact (**Table 9-25**).

Table 9-25: Summary of Operational Impact 3: Introduction of New Habitat in the Form of Project Infrastructure

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Operation and Maintenance						
Impact 3: Introduction of new habitat in the form of project infrastructure	Benthic habitats within MDZ	Medium	Negligible	Minor Adverse	None required	Minor Adverse

9.6.3.4. Operational Impact 4: Temporary Physical Disturbance of Seabed Caused by Maintenance Activities and Repowering

167. As with other marine energy infrastructures, there will be a requirement for planned and unplanned maintenance activities throughout the operation phase of the Project. These activities may vary in nature, however the maintenance activities considered likely to cause disturbance impacts are cable repairs and repowering works.

168. Cable repairs will result in localised and temporary disturbance of the seabed up ten times throughout the project life, each requiring around 5 days of repair work. This equates to a total of a possible 3,000 m^2 of temporary disturbance occurring due to project maintenance works throughout the project life, equal to around 0.007 % of the MDZ total area.

169. As a worst-case scenario, repowering works of 50 % of the berths is predicted, which will involve removal of existing tenant infrastructure and the re-installation of new infrastructure.

170. Based on the values in **Table 9-16**, a total area of 377,400 m^2 is predicted to be subject to additional temporary seabed disturbance via repowering. Therefore, a total of 380,400 m^2 (0.38 km^2) of seabed will be temporarily disturbed for cable repairs and repowering. All this activity will take place within the main MDZ array site (35 km^2), meaning that 1.1 % of the MDZ array area will be affected.

171. Due to the low frequency of these activities the magnitude of the effect is judged to be negligible as the amount of predicted temporary habitat disturbance will cover a very small extent of the development site (far less than the seabed footprint), for very short, discrete periods.

172. The MarLIN pressure factor relevant to this impact and used to inform this assessment is ‘physical disturbance and abrasion’. As discussed within Impact 1, the dominant and most sensitive receptors within the MDZ are VER habitat group 9 (High energy infralittoral and circalittoral rock/ coarse sediment with Annex I stony/bedrock reef) and VER habitat group 10 (Circalittoral Sabellaria reefs – Annex I biogenic reefs). These groups contain possible Annex I reef habitats (biogenic, bedrock and stony), and were both assigned a medium sensitivity.

173. The most sensitive receptors (VER habitat group 9 and 10) have a medium sensitivity to physical disturbance and abrasion, and an overall negligible magnitude. Therefore, a **minor adverse** impact on these receptors during operational phase maintenance and/or repowering activities.

9.6.3.4.1. Mitigation

174. As it was concluded that the impact was of minor adverse significance no mitigation measures are proposed. Efforts shall be made to minimise operation and maintenance works undertaken to reduce impacts beyond the worst case assessed here.

9.6.3.4.2. Residual Impact

175. No mitigation is proposed. The residual impact remains of **minor adverse** significance (**Table 9-26**).

Table 9-26 Summary of Operational Impact 4: Temporary Physical Disturbance of Seabed Caused by Maintenance and Repowering Activities

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Operation and Maintenance						
Impact 4: Temporary physical disturbance of seabed caused by maintenance and repowering activities	VER Habitat Group 9 and 10	Medium	Negligible	Minor Adverse	None required	Minor Adverse

9.6.4. Potential Impacts during Decommissioning

9.6.4.1. Decommissioning Impact 1: Physical Disturbance to Habitats and Species and Temporary Habitat Loss

176. Within the decommissioning phase, temporary disturbance and habitat loss will occur due to the removal of the project related infrastructure. The removal of infrastructure and cabling from the seabed will result in a temporary loss of habitat and physical disturbance and therefore can be assessed in the same way as for construction which was adjudged to be of low magnitude (**Section 9.6.2.1**).

177. In the event that the cables on the intertidal zone are trenched and not laid via HDD methods, the decommissioning phase would require re-opening of the trench to extract the cable in a similar process to the construction phase. This trench would also be back filled with the removed material as within the construction phase.

178. The impacts are predicted to be similar or less than those which occurred within the construction phase and will be localised and for a short duration. Therefore, the magnitude of impact has been assessed as low. Given that the habitats and species which will be disturbed are predicted to be similar to those which will be disturbed within the construction phase, a medium sensitivity has been assigned for the benthic biotopes which will be disturbed. An overall **minor adverse** impact is assigned for the potential disturbance and temporary loss of habitats within the decommissioning phase.

9.6.4.1.1. Mitigation

179. Topic-specific mitigation will be conducted to ensure minimal loss of habitats and species within the operational phase. Following consent, pre-construction surveys would be carried out to check for the presence of any rare or protected habitats and species. Following these surveys, micro-siting of the cable would be used to mitigate impacts to these receptors where possible. This would inform areas which should be avoided and therefore minimal loss of important or protected habitats will occur.

9.6.4.1.2. Residual Impact

180. Although the impacts will be lessened, a **minor adverse** impact will remain for this activity (**Table 9-27**).

Table 9-27 Summary of Impact 12: Physical Disturbance to Habitats and Species and Temporary Habitat Loss

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Decommissioning						
Impact 12: Physical disturbance to habitats and species and temporary habitat loss	VER Habitat Group 9 and 10	Medium	Low	Minor Adverse	Following consent, pre-construction surveys and possible micro-siting will be conducted to allow for identification of important areas of habitat.	Minor Adverse

9.6.4.2. Decommissioning Impact 2: Increases in Suspended Sediment Concentration and Subsequent Deposition

181. Throughout the decommissioning phase there is potential for decommissioning activities such as drilling to disturb sediments, either from the sea bed surface or from below the sea bed

(depending on foundation type) and release them into the water column as a plume which may then be deposited within or around the MDZ.

182. However, the disturbance of sediments on the sea bed and release of them into the water column as a plume is lower than the effects arising from installation of foundations within the construction phase. This is primarily because the removal activities will cause less direct interference (i.e. no pre-drilling) and the Project substrate is largely characterised by bedrock with little surface sediment other than occasional gravel, cobbles and boulders, which would not form a plume.

183. Therefore, it is unlikely that there will be impacts to any of the identified VER groups within the MDZ, and a low sensitivity has been assessed for increased sediment plumes and deposition. As the magnitude of effect is deemed to be negligible and the sensitivity as low, an overall **negligible** impact is predicted.

9.6.4.2.1. Mitigation

184. As the impact assessment for potential increased suspended sediments and smothering is **negligible**, no specific mitigation is proposed.

9.6.4.2.2. Residual Impact

185. An overall **negligible** significance remains as no mitigation is required (**Table 9-28**).

Table 9-28 Summary of Impact 13: Increases in Suspended Sediment Concentration and Subsequent Deposition

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Decommissioning						
Impact 13: Increases in suspended sediment concentration and subsequent deposition	Benthic habitats within MDZ	Low	Negligible	Negligible	None required	Negligible

9.6.4.3. Decommissioning Impact 3: Permanent Loss of Habitat

186. Within the decommissioning phase, the hard substrates which have been placed within the subtidal area of the MDZ will be removed and therefore a loss of habitat will occur for those species which may have colonised it over the project lifetime. However, this loss of species and habitat will be balanced by the re-exposure of seabed habitats within the offshore site that can then be recolonised, therefore the impact is **negligible.**

9.6.4.3.1. Mitigation

187. As the impact assessment for permanent habitat loss during decommissioning is **negligible**, no specific mitigation is proposed.

9.6.4.3.2. Residual Impact

188. An overall **negligible** significance remains as no mitigation is required (**Table 9-29**).

Table 9-29 Summary of Impact 14: Permanent Loss of Habitat

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Decommissioning						
Impact 14: Permanent loss of habitat	Benthic habitats within MDZ	Negligible	Negligible	Negligible	None required	Negligible

9.6.5. Cumulative Impacts

As observed within the above assessments, the majority of impacts which are associated with benthic ecology are restricted to the immediate footprint of the Project. Therefore, it is only projects that will affect the same area of seabed, or more generally, the same local resource of benthic habitats that require consideration. The only identified project is Minesto's Holyhead Deep project, an 80 MW installation of tidal energy devices, delivered in a phased manner, located a short distance due west of the MDZ Project.

9.6.5.1. Potential Cumulative and In-Combination Impacts during Construction

189. The main potential cumulative and in-combination impacts during construction and installation relate to the direct physical disturbance and habitat loss caused by the installation of Project infrastructure on the seabed. Construction activities of the Project with the Minesto project may overlap on a temporal scale as the construction and installation of the Minesto project is following a phased approach and their seabed footprints should be considered in the overall footprint of habitat loss in the region.

190. The temporal overlap of construction activities presents a possible risk of elevated suspended sediment concentrations within the region beyond a level which would occur for individual project construction activities. However, as discussed within **Chapter 7, Metocean Conditions and Coastal Processes**, there is no possibility of changes in tidal flow interacting between projects, due to the alignment of flood and ebb flows off the coast of Anglesey (i.e. the two projects are not upstream/downstream of each other). The predicted impacts of Minesto's Holyhead Deep project on coastal processes have been assessed as being not significant in their own right (Minesto, 2016), and this conclusion is considered equally valid when both projects are considered in combination.

191. In comparison to the amount of comparable habitat identified in the survey area, the overall area of habitat that will be impacted by the Minesto project and the Project is small and it is predicted that no significant impacts should occur. Further, Minesto and Morlais may in future investigate options to share the future export cable; which will reduce the footprint of both projects and ensure that any habitat loss associated with these upcoming projects is kept to a minimum.

192. Although there is an increased risk of the introduction of INNS to the marine environment due to an increased amount of vessel traffic in the area and thus an increased window of opportunity, if

all projects abide to agreed mitigation measures and follow relevant guidelines then the probability will remain low. Therefore, the likelihood of simultaneous construction cumulatively impacting vulnerable benthic communities and receptors within the wider area is extremely low and is considered not significant.

9.6.5.2. Potential Cumulative and in-Combination Impacts during Operation and Maintenance

193. During the operational and maintenance phase, there is potential for impacts to act in-combination with other developments within the area. The two main impact pathways are:

- Modified hydrodynamic regime and sediment regime; and
- New hard substrates and their potential for INNS.

194. The small scale of the Project and the lack of impact this has on the environment within the MDZ makes it unlikely to interact with other developments within the region. The Minesto project is also of a small scale and is unlikely to have an impact on the hydrodynamics within its project space. Therefore, it is unlikely that there will be a significant alteration to the hydrodynamics in a regional context. Due to both of these projects being situated within areas of hard substrate and low levels of soft sediments, it is unlikely that scour pits will form around either projects infrastructure, and thus unlikely for an interaction to occur between the two projects.

195. Both the Project and the Minesto project involve introduction of hard substrate into a marine environment, which presents a risk of colonisation, inward migration and the settlement of species. Further, this hard substrate presents a substrate which could be utilised by INNS. However, as both of these projects are located within predominately hard substrate areas, the effects of possible colonisation of the infrastructure will not be as pronounced as those which would occur if the infrastructure was to be placed within soft sediments, as this would lead to the colonisation of an environment by species which are not typically found in this area. Further, due to the large level of available natural hard substrate (stony reef, bedrock etc), a large sink will occur to these readily available habitats.

196. The current dominance of hard substrates within the MDZ and the wider region suggests additional hard substrate through infrastructure will not present a vastly different environment for INNS than already within the region. Therefore, it is unlikely that the new infrastructure and additional hard substrates within the region will lead to a significant impact.

9.6.5.3. Potential Cumulative and in-Combination Impacts During Decommissioning

197. The main impact with any potential for cumulative effects at the decommissioning stage is direct physical disturbance and habitat loss. It is unlikely that the other projects will be decommissioned at the same time as the Project. Even if it is, the potential cumulative/in-combination impacts will be comparable to those during construction.

9.6.6. Inter-Relationships

198. **Table 9-30** lists out the inter-relationships between this chapter and other chapters within the ES.

Table 9-30 Inter-Topic Relationships

Topic and description	Related Chapter	Where addressed in this Chapter	Rationale
Metocean Conditions and Coastal Processes	Chapter 7	Section 9.6.2	Both chapters consider the potential effects of the project on sediment concentrations in the water column

199. Habitat loss and disturbance is also discussed separately in a number of other chapters, including **Chapter 8, Marine Water and Sediment Quality** and **Chapter 10, Fish and Shellfish Ecology.**

9.6.7. Interactions

200. The impacts identified and assessed in this chapter have the potential to interact with each other, which could give rise to synergistic impacts as a result of that interaction. The worst case impacts assessed within the chapter take these interactions into account and for the impact assessments are considered conservative and robust. For clarity the areas of interaction between impacts are presented in **Table 9-31**, along with an indication as to whether the interaction may give rise to synergistic impacts.

Table 9-31 Potential Interaction Between Impacts

Potential interaction between impacts					
Construction	1: Physical disturbance and temporary habitat loss	2: Increased suspended sediment concentration	3: Pollution of water and sediment	4: Physical disturbance (intertidal)	5: Potential spread of non-native
1: Physical disturbance to habitats and species and temporary habitat loss	-	Yes	Yes	Yes	Yes
2: Increased suspended sediment concentration and sediment deposition	Yes	-	No	Yes	No
3: Pollution of water and sediment through accidental events	Yes	No	-	Yes	No

3: Permanent loss of habitat	Yes	No	-	

9.7. SUMMARY

201. This chapter provides an overview on the potential impacts which may occur within the several stages associated with the development of the Project: construction, operation and maintenance, and decommissioning to the benthic and intertidal ecology of the MDZ.

202. **Table 9-32** collates the determinations of each of the impacts assessed and is presented as a summary of the determinations. It is evident that the majority of the impacts to the benthic and intertidal ecology throughout the various stages of development are likely to be of minor adverse significance, even when assessed with the worse-case scenario. Therefore, the effects on the benthic and intertidal ecology are unlikely to cause long-term changes to the MDZ environment and surrounding region, either through direct changes in the species composition or due to changes in sediment structure.

Table 9-32 Summary of potential impacts for the benthic ecology receptors associated with the development of the project

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
Construction						
Impact 1: Physical disturbance to habitats and species and temporary habitat loss	VER Group 9 and 10	Medium	Low	Minor Adverse	▪ Mitigation will be conducted to ensure minimal disturbance to and loss of habitats and species during construction via pre-construction surveys and micro-siting.	Minor Adverse
Impact 2: Increased suspended sediment concentration and sediment deposition	VER Group 10	Low	Negligible	Negligible	▪ None required	Negligible

Impact 3: Pollution of water and sediment through accidental events	Benthic habitats within MDZ	High	Low	Moderate	▪ Development of an Emergency Response Cooperation Plan (ERCoP) with guidance set out by MCA in MGN 371, issued and approved by MCA;
					▪ Development of a Marine Pollution Contingency Plan and Vessel Management Plan, which would include the following measures:
					  ▪ Notice to Mariners to be issued to reduce collision risks;
					  ▪ Vessels associated with all Project operations will comply with IMO/MCA codes for prevention of oil pollution and any vessels over 400 GT will have on board SOPEPs;
						Minor Adverse

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
					▪ Vessels associated with all Project operations will carry on-board oil and chemical spill mop up kits; and ▪ Where possible, vessels will avoid working in poor weather conditions.	
Impact 4: Physical disturbance to intertidal habitats and species during landfall works	VER Group 1, 9, 12	Medium	Medium	Moderate	▪ Agree work method with NRW to minimise disturbance, using excavated materials to backfill, and to safeguard some boulders from top layer pre trench excavation, for replacement at end of backfilling.	Minor Adverse
Impact 5: Potential spread of non-native	Benthic habitats within MDZ	Medium	Medium	Moderate	▪ Compliance with guidelines, risk assessment of project vessels for INNS and further mitigation measures if required.	Minor Adverse
Operation and Maintenance						
Impact 1: Long Term Loss of Benthic Habitat via (a) Initial Placement of Project Infrastructure and (b) Repowering	VER Habitat Group 1, 9 and 12	Medium	Medium	Moderate	▪ Following consent, pre-construction surveys and possible micro-siting will be conducted to allow for identification of important areas of habitat.	Minor Adverse
Impact 2: Changes in hydrodynamic and inter-related effects on benthic ecology	Benthic habitats within MDZ	Low	Medium	Minor Adverse	▪ None required	Minor Adverse
Impact 3: Introduction of new habitat in the form of project infrastructure	Benthic habitats within MDZ	Medium	Negligible	Minor Adverse	▪ None required	Minor Adverse

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
Impact 4: Temporary physical disturbance of seabed caused by maintenance and repowering activities	VER Habitat Group 9 and 10	Medium	Negligible	Minor Adverse	▪ None required	Minor Adverse
Decommissioning						
Impact 1: Physical disturbance to habitats and species and temporary habitat loss	VER Habitat Group 9 and 10	Medium	Low	Minor Adverse	▪ Following consent, pre-construction surveys and possible micro-siting will be conducted to allow for identification of important areas of habitat.	Minor Adverse
Impact 2: Increases in suspended sediment concentration and subsequent deposition	Benthic habitats within MDZ	Low	Negligible	Negligible	▪ None required	Negligible
Impact 3: Permanent loss of habitat	Benthic habitats within MDZ	Negligible	Negligible	Negligible	▪ None required	Negligible

GLOSSARY OF TERMINOLOGY

Beam trawl	A trawl net whose lateral spread during trawling is maintained by a beam across its mouth.
Benthic	Relating to, or occurring at the sea bottom.
Bony fish	Any of a major taxon (class Osteichthyes or superclass Teleostomi) comprising fishes with a bony rather than a cartilaginous skeleton.
Clupeid	Any of various fishes of the family Clupeidae, which includes the herrings, sprats, sardines and shads.
Crustacean	An arthropod of the large, mainly aquatic group Crustacea, such as a crab, lobster, shrimp, or barnacle.
Demersal	Living on or near the seabed.
Diadromous	Migrating between fresh and salt water.
Elasmobranch	Any cartilaginous fish of the subclass Elasmobranchii which includes the sharks, rays and skates.
Epibenthic	Relative to the flora and fauna living on the surface of the sea bottom.
Gadoid	A bony fish of an order (Gadiformes) that comprises the cods, hakes, and their relatives.
Otter trawl	A trawl net fitted with two ‘otter’ boards which maintain the horizontal opening of the net.
Pelagic	Living in the water column.
Swim bladder	A gas-filled sac present in the body of many bony fish, used to maintain and control buoyancy.

10. FISH AND SHELLFISH ECOLOGY

10.1. INTRODUCTION

1. Menter Môn Morlais Limited (Menter Môn) proposes the development of 240 MW of tidal generating capacity within the Morlais Demonstration Zone (MDZ). The development of the Morlais Project (the Project) will support the development of renewable energy technology objectives of the Anglesey and Gwynedd Joint Local Development Plan (JLDP), providing a consented tidal technology demonstration zone which supports installation, testing and commercial demonstrations of tidal energy devices. The Project will also provide opportunities for the local communities via direct employment and support of the local supply chain.

2. The Project will include communal infrastructure for tidal technology developers which provides a shared route to a local grid connection via nine export cable tails, an onshore landfall substation, and an onshore electrical cable route to a grid connection via a grid connection substation.

3. This chapter of the Environmental Statement (ES) aims to provide an assessment of potential impacts on fish and shellfish ecology within Welsh waters which may arise during the construction, operation and maintenance, repowering, and decommissioning of the Project.

4. This chapter characterises the baseline environment of fish and shellfish, as discerned from local and regional data in the published and 'grey literature'. The chapter then identifies potential impacts on the fish and shellfish receptor species that can arise through the Project phases, presents an impact assessment and associated results, and where applicable proposes mitigation measures. Additional relevant information has been used from other chapters of the ES, specifically:

   - **Chapter 7, Metocean Conditions and Coastal Processes**;
   - **Chapter 9, Benthic and Intertidal Ecology**; and
   - **Chapter 14, Commercial Fisheries**.

5. This chapter has been prepared by MarineSpace Ltd on behalf of Menter Môn.

10.2. POLICY, LEGISLATION AND GUIDANCE

6. A detailed overview of the policy and legislation surrounding this project can be found in **Chapter 2, Policy and Legislation**.

7. The Project is seeking consent for a Transport and Works Act Order from the Welsh Government and a Marine Licence from Natural Resources Wales (NRW). Although this project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is of a scale equivalent to a Nationally Significant Infrastructure Project (NSIP). Therefore, guidance for the DCO procedure constitutes the most appropriate guidance for a project of this scale and as such can be used to inform the approach for this Project. Guidance that is relevant to assessing impacts on fish and shellfish for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to fish and shellfish ecology include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011a); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011.

8. Details of specific policies within EN-1 and EN-3 used to inform this assessment are provided below.

9. Other relevant legislation has been considered during this assessment (see **Chapter 2, Policy and Legislation**). The following are of particular relevance to the assessment of fish and shellfish ecology:

- EU Habitats Directive (Directive 92/43/EEC);
- Conservation of Habitats and Species Regulations 2010 (the Habitats Regulations) implements species protection requirements of the Habitats Directive in England in inshore waters;
- UK Post-2010 Biodiversity Framework, superseding the UKBAP the UK Governments response to the Convention on Biological Diversity (CBD) 1992;
- Conservation of European Wildlife and Natural Habitats Convention (Bern convention);
- Wildlife and Countryside Act 1981;
- The Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES); and
- Environment (Wales) Act 2016 (which incorporates the same list of species of principal importance as originally presented in Sections 41 and 42 of the Natural Environment and Rural Communities Act 2006.

10.2.1. National Policy Statement

10. The Project is seeking consent for a Transport and Works Act Order from the Welsh Government and a Marine Licence from Natural Resources Wales (NRW). Although this project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts on marine water and sediment quality for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to marine water and sediment quality include:

- Overarching NPS for Energy (EN-1) (Department of Energy and Climate Change (DECC) 2011a); and
- NPS for Renewable Energy Infrastructure (EN-3), July 2011 (DECC, 2011b).

11. Details of specific policies within EN-1 and EN-3 used to inform this assessment are provided in below. The specific assessment requirements for fish and shellfish ecology are detailed, together with an indication of the paragraph numbers of the chapter where each is addressed.

Table 10-1 NPS EN-1 and EN-3 Assessment Requirements Relevant to Fish and Shellfish Ecology

NPS Requirement	NPS Reference	ES Reference
"There is the potential for the construction and decommissioning phases, including activities occurring both above and below the seabed, to interact with seabed sediments and therefore have the potential to impact fish communities, migration routes, spawning activities and nursery areas of particular species. In addition, there are potential noise impacts, which could affect fish during construction and decommissioning and to a lesser extent during operation."	EN-3, Paragraph 2.6.73	Potential impact to fish and shellfish ecology arising from construction and decommissioning activities associated with the seabed are discussed in throughout the Impact Assessment in **Section 10.6**.
The applicant should identify fish species that are the most likely receptors of impacts with respect to feeding areas; spawning grounds; nursery grounds; overwintering areas for crustaceans and migration routes;	EN-3, Paragraph 2.6.74	Fish and shellfish species present within the study area have been identified through desk-based assessment of available data and are presented in **Section 10.5**.
Where mitigation measures are applied to offshore export cables to reduce electromagnetic fields (EMF) the effects on sensitive species during operation are unlikely to be a reason for PINS to have to refuse to grant consent. Once installed, operational EMF impacts are unlikely to be of sufficient range or strength to create a barrier to fish movement;	EN-3 Para 2.6.75	EMF impacts to fish and shellfish could arise during the operation of the Project. These are assessed in **Section 10.6.5.6**.
EMF during operation may be mitigated by use of armoured cable for inter-array and export cables which should be buried at a sufficient depth	EN-3 Para 2.6.76	EMF impacts and any proposed mitigation measures are discussed in **Section 10.6.5.6**.
During construction, 24 hour working practices may be employed so that the overall construction programme and the potential for impacts to fish communities are reduced in overall time.	EN-3 Para 2.6.77	24-hour working practices will be employed for offshore construction (see **Chapter 4, Project Description**).

10.2.2. Marine Policy Statement

12. The Marine Policy Statement (MPS) adopted by all UK administrations in March 2011 provides the policy framework for the preparation of marine plans and establishes how decisions affecting the marine area should be made in order to enable sustainable development. The MPS sets out a vision of having 'clean, healthy, safe, productive and biologically diverse oceans and seas' by supporting the development of Marine Plans. It also sets out the framework for environmental, social and economic considerations that need to be considered in marine planning.

10.2.3. Wales National Marine Plan

13. By adopting the MPS, the Welsh Government committed to the requirement to introduce Marine Plans for Wales.

14. The Welsh Government is currently developing the first marine plan for Welsh inshore and offshore waters, the Welsh National Marine Plan (WNMP). The Plan is being developed in accordance with the Marine and Coastal Access Act (MCAA) 2009, the MPS and the Maritime Spatial Planning Directive, a draft version has been issued for consultation (discussed further in Chapter 2, Policy and Legislation).

15. Objective 10 of the WNMP, “to maintain and enhance the resilience of marine ecosystems and the benefits they provide in order to meet the needs of present and future generations”, is of relevance to this chapter as this covers policies and commitments on the wider ecosystem, as set out in the MPS including those to do with the Marine Strategy Framework Directive and the Water Framework Directive, as well as other environmental, social and economic considerations.

16. **Table 10-2** sets out other national and regional policies which are particularly relevant to the Project.

Table 10-2 National and Regional Policy Requirements Relevant to Fish and Shellfish Ecology

Policy Description	Reference	ES Reference
MPS		
Noise resulting from a proposed activity or development in the marine area or in coastal and estuarine waters can have adverse effects on biodiversity although knowledge of the extent of impacts is limited and there are few systematic monitoring programmes to verify adverse effects. Man-made sound emitted within the marine environment can potentially affect marine organisms in various ways. It has the potential to mask biologically relevant signals; it can lead to a variety of behavioural reactions, affect hearing organs and injure or even kill marine life. Manmade sound sources of primary concern with regard to disturbance of marine life are explosions, shipping, seismic surveys, offshore construction and offshore industrial activities, for example dredging, drilling and piling, sonar of various types and acoustic deterrent devices.	Section 2.6.3.1	The effects of underwater noise on migratory and non-migratory fish have been assessed using noise modelling from a similar recent tidal energy project, the PTEC project as well as a technical note prepared for this project (Subacoustech, 2019) This included species considered sensitivity to noise. Noise produced from a variety of activities (both construction and operation) have been included. See **Sections 10.6.4.1** and **10.6.5.1**.
Renewable energy developments can potentially have adverse impacts on marine fish and mammals, primarily through construction noise and may displace fishing activity and have direct or indirect impacts on other users of the sea, including mariners. Certain bird species may be displaced by offshore wind turbines, which also have the potential to form barriers to migration or present a collision risk for birds. Their foundation designs are likely to have an effect on hydrodynamics and consequent sediment movement. This includes potential scouring of sediments around the bases of turbines. These and other potential adverse impacts, together with potential mitigation measures, are considered in the National Policy Statement for Renewable Energy Infrastructure (EN-3).	Section 3.3.24	Potential impacts on fish and shellfish arising from the Project are assessed in **Sections 10.6.4**, **10.6.5** and **10.6.6**. Displacement of fishing activity is considered in **Chapter 14, Commercial Fisheries**
Marine energy deployments, that is wave and tidal deployments, may pose potential risks to the environment if inappropriately sited. However, the level of risk and ecological significance is largely unknown since, in particular, tidal stream and wave technologies are at a relatively early stage of development. Studies of tidal range	Section 3.3.25	A desk-based review of available data has been used to determine the species present (**Section 10.5.3**) and the potential impacts to

Policy Description	Reference	ES Reference
technologies, including barrages, have indicated that these structures can have adverse impacts on migratory fish and bird species and on the hydrodynamics of the estuarine environments in which they are situated. To underpin the marine planning process further research is needed to develop a better understanding of the potential impacts that marine technologies might have on potentially sensitive environmental features. For example, adaptation and mitigation methods for such impacts may be supported by detailed monitoring programmes and co-ordinated research initiatives, including post deployment of devices.		these species are assessed in **Section 10.6** to be of minor adverse significance.
Draft WNMP		
Proposals should demonstrate how they contribute to the protection, restoration and/or enhancement of marine ecosystems	ENV_01: Resilient marine ecosystems	Potential impacts to fish and shellfish are assessed in **Section 10.6** to be of minor adverse significance.
Proposals should demonstrate how they: · avoid adverse impacts on individual Marine Protected Areas (MPAs) and the coherence of the network as a whole; · have regard to the measures to manage MPAs; and · avoid adverse impacts on non-marine designated sites.	ENV_02: Marine Protected Areas	The conservation importance of fish and shellfish species is presented in **Section 10.5.** Potential impacts to these species are assessed in **Section 10.6** to be of minor adverse significance.
Proposals should include biosecurity measures to reduce the risk of introducing and spreading invasive non-native species.	ENV_03: Invasive non-native species	The assessment of the impact of invasive non-native species is addressed in **Chapter 9, Benthic and Intertidal Ecology**.
Proposals should demonstrate that they have considered man-made noise impacts on the marine environment and, in order of preference: a) avoid adverse impacts; and/or b) minimise impacts where they cannot be avoided; and/or c) mitigate impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding	ENV_05: Underwater noise	The effects of underwater noise on migratory and non-migratory fish have been assessed using noise modelling from a similar recent tidal energy project, the PTEC project as well as a technical note prepared for this project (Subacoustech, 2019) This included species considered sensitivity to noise. Noise produced from a variety of activities (both construction and operation) have been included. See **Sections 10.6.4.1** and **10.6.5.1**.

Policy Description	Reference	ES Reference
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative impacts are assessed in **Section 10.6.7** and in **Chapter 26**
Anglesey and Gwynedd Joint Local Development Plan (JLDP)		
All impacts on landscape character, heritage assets and natural resources have been adequately mitigated, ensuring that the special qualities of all locally, nationally and internationally important landscape, biodiversity and heritage designations, including, where appropriate, their settings are conserved or enhanced	Policy ADN 3: Other Renewable Energy and Low Carbon Technologies	The impact assessment is included within **Section 10.6** and includes mitigation measures to reduce impact significance.

10.3. CONSULTATION

17. An Environmental Impact Assessment (EIA) scoping process was undertaken for this project. An EIA Scoping Document (Royal HaskoningDHV, 2018) was produced and submitted to the regulators, who consulted with the statutory bodies and key stakeholders upon the contents. The project went through three rounds of scoping, in 2015, 2017 and 2018. All scoping comments from 2018 pertaining to this chapter have been presented in **Table 10-3**. These comments have been addressed fully in this chapter, with the location of the relevant information highlighted in the response column for ease of location.

Table 10-3 Consultation Responses Pertaining to Fish (Including Migratory Fish) and Shellfish from the 2018 Scoping Round

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping Comments	Marine Fish: The documents referred to in footnotes 50 and 51, which have been used to inform the described marine fish baseline, are over 20 years old. Baseline information is expected to be informed by up to date studies, or evidence should be provided to demonstrate that these are still relevant. The Applicant is recommended to make efforts to agree the species to be included within the assessment with NRW; taking into account the comments made in NRW's consultation response (see Appendix 1 of this Scoping Opinion).	More recent references have been used to inform the marine fish baseline, such as Ellis et al. (2012) and Aires et al. (2014). See **Section 10.5.4** to **10.5.6**.
Planning Inspectorate	2018 Scoping Comments	Shellfish: The Fish and Shellfish Ecology chapter does not identify the European Shellfish Water designation that is identified in Section 7.2.1.1 of the Scoping Report. Appropriate cross reference should be made to the Marine Sediment and Water Quality chapter.	The European Shellfish Water designation has now been mentioned in **Section 10.5.7.3** Please also see **Figure 8-1** (**Volume II**) and **Chapter 8, Marine Water and Sediment Quality.**

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping Comments	Potential Impacts: Table 8-7 of the Scoping Report states that the significance of effect for a number of potential impacts would be dependent on construction methods and project design. It is understood that the precise detail of the construction methods will not be known at the time of application. On this basis, the ES should ensure that a worst case scenario attributable to construction is assessed.	The worst-case scenario approach has been adopted throughout this chapter.
Planning Inspectorate	2018 Scoping Comments	Loss of shellfish habitat: The Scoping Report has identified the potential for loss of shellfish habitat through the placement of devices and the swept area of mooring cables. The loss of habitat (including seabed, spawning or nursery grounds) for demersal fish should also be assessed in the ES.	Loss of habitat for demersal fish (and other fish groups) has been considered in the impacts as well as the loss for shellfish. See **Section 10.5.5**.
Planning Inspectorate	2018 Scoping Comments	Impacts on fish and shellfish through a decrease in water quality: The ES should assess the likely significant effects from increased turbidity on larvae of fish and shellfish species.	A short description of the potential effects of turbidity on larvae has been included; see **Section 10.6.4.3**.
Planning Inspectorate	2018 Scoping Comments	EMF: The Scoping Report identifies EMF as a potential barrier to migratory fish. No reference is made of impacts to non migratory fish. This should be considered and if significant effects are likely this should be assessed within the ES.	The effects of EMF on non-migratory fish and shellfish have been included. See **Section 10.6.5.7**.
Planning Inspectorate	2018 Scoping Comments	Underwater noise: The Scoping Report identifies the potential for underwater noise to displace migratory fish. No reference is made of impacts to non-migratory fish (e.g. behavioural impacts, injury or death). Impacts to non-migratory fish which could result in significant effects should be assessed within the ES. The ES should also justify the approach to the assessment based on fish species sensitivity to underwater noise. The assessment of underwater noise during construction should include all construction activities e.g. piling, vessels, seabed preparation and cable installation.	The effects of underwater noise on non-migratory fish have been included in this chapter. The chapter has used species-specific sensitivity levels in the approach. Noise produced from a variety of activities (both construction and operation) have been included. See **Sections 10.6.4.1** and **10.6.5.1**.
Planning Inspectorate	2018 Scoping Comments	Site specific surveys: The need for and design of site specific surveys should be discussed and agreed with NRW.	The rationale for not conducting site specific surveys has been included under **Section 10.4.4**.

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping Comments	Changes to species composition: Table 9-4 has identified the potential for changes in abundance of commercial fisheries target species. If significant effects are likely, changes to species composition should also be assessed in the Fish and Shellfish chapter of the ES.	**Chapter 14, Commercial Fisheries** has been reviewed. The greatest impact predicted for commercial fisheries was minor adverse, which is not significant. Therefore, there are no significant impacts for commercial fisheries that need to be included in this chapter.
Planning Inspectorate	2018 Scoping Comments	Biosecurity: The ES should assess the potential impacts from the spread of non-native invasive species. Any measures to mitigate the spread of this species should be identified in the ES.	The assessment of the impact of invasive non-native species is addressed in **Chapter 9, Benthic and Intertidal Ecology**. A cross-reference to this chapter has been added to **Section 10.6.1**.
National Resource Wales (NRW) (for PINS)	2018 Scoping Comments	The assessment of fish species to inform the Environmental Statement needs to identify all possible fish species that may be affected by the proposed development and indicate the relevant legislation for each, for example: Common Fisheries Policy zero TAC species, UK Biodiversity Action Plan species, Section 7 Environment Act species, IUCN European Red List species etc. Assessment should consider the impacts of all stages of development (i.e. construction, operation and decommissioning).	All of the listed legislation has been included when assessing the fish species to be included in the assessment. See **Table 10-10, Table 10-12, Table 10-14, Table 10-17**.
NRW (for PINS)	2018 Scoping Comments	In light of the above information we advise that species such as the spurdog or spiny dogfish *Squalus acanthias* will need to be included as a potential impact receptor in the ES; it is known to use the area and is classed as vulnerable in the IUCN Red List. This, and other elasmobranch species may be impacted by, for example, electromagnetic field effects and so should be included in the ES for assessment.	The spiny dogfish and other elasmobranch species have been included in the assessment. See **Section 10.5.4** for the elasmobranch species included, and **Section 10.6.5.7** for EMF effects.
NRW (for PINS)	2018 Scoping Comments	The Pembrokeshire Marine SAC fish species features of sea lamprey, river lamprey and allis shad (note that twaite shad is missing) are included in Table 8-1 but Pembrokeshire Marine SAC has been	The Pembrokeshire Marine SAC (Site code 13116) has been included in this assessment (as shown in

Consultee	Date/Document	Comment	Response
		omitted from Table 8-6 Relevant SACs for migratory fish. NRW welcomes the statement in Table 11-1 that migratory fish will be fully considered in the ES, including the provision of a justification where specific sites and species are scoped out.	**Figure 10-4, Volume II**) as well as the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**). Migratory fish have been fully considered in this chapter, aligned with the rationale in the HRA.
NRW (for PINS)	2018 Scoping Comments	Section 8.4.2.1 of the EIA scoping report states “that shellfish are the only commercial species landed at Holyhead”. This statement is incorrect as fish species are also landed there. The EIA suggests ‘that no scallop vessels at Holyhead are licenced for scallop fishing’, however, several vessels fish for scallops from Holyhead. Longlining fishing for rays occasionally occurs off western Anglesey with vessels from Holyhead participating.	A brief overview of commercial fisheries information has been included in this chapter, with cross-reference made to **Chapter 14, Commercial Fisheries**
NRW (for PINS)	2018 Scoping Comments	We welcome the acknowledgement of the potential impact pathways identified for Annex II species (fish) features and natural fish and shellfish in Table 8.1 and Table 8.7. We note, however, that the potential impact to migratory and non-migratory fish from ‘collision risk with devices’ has been identified as ‘unlikely to be significant’, despite the applicant indicating that migratory pathways are not well understood, and that more information is required to assess potential impacts to non-migratory fish. A full examination and evidenced justification in support of this view will be required within the ES.	A full impact assessment of collision risks with migratory and non-migratory fish has been included in this chapter. See **Section 10.6.5.6.**
NRW (for PINS)	2018 Scoping Comments	We advise that impacts on migratory fish from underwater noise should include consideration of impacts on hearing specialists such as herring which are a prey species of marine mammals. Other impacts which we recommend are assessed within the ES include possible impacts on larvae of fish and shellfish species from increased turbidity.	The impact on migratory fish from underwater noise has been assessed using noise modelling from a similar recent tidal energy project, the PTEC project as well as a technical note prepared for this project (Subacoustech, 2019) This included species considered sensitivity to noise. See **Section 10.6.4.1**. The effect of turbidity on larvae has been included in **Section 10.6.4.3.1**

Consultee	Date/Document	Comment	Response
NRW (for PINS)	2018 Scoping Comments	We welcome the applicant's indication in Table 11.1 that transitional fish species (such as bass, whiting and herring) will be considered as part of the wider fish assessment which will include consideration of seasonal variation in fish spawning and larval activity. We maintain that the ES should differentiate between transitional and migratory fish assemblages where possible.	Transitional fish species and their general seasonality have been included in the assessment. See **Table 10-13** for an example.
NRW	2018 Scoping Comments	No information is provided on the proposed approach to assessing potential underwater noise effects. This should follow the latest guiding principles for the assessment of the impacts of underwater noise. This includes applying an appropriate acoustic model, published exposure criteria or acoustic thresholds and relevant noise sources and model input data. The limitations and constraints of any approach should be set out. The noise assessment should also include a general review of the latest available scientific evidence of the observed responses of fish to different types of underwater sound for context. Consideration should be given to the sensitivity of fish to particle motion (not just sound pressure level) recent research indicated this to be an equally or potentially more important than sound pressure in some fish	The noise modelling output from a similar project (PTEC, 2014) has been used within this assessment, plus outputs from a recent technical note on subsea noise (Subacoustech, 2019).
NRW	2018 Scoping Comments	Impacts on migratory fish from underwater noise should include consideration of impacts on hearing specialists such as herring which are a prey species of marine mammals. Other impacts which should be assessed within the ES include possible impacts on larvae of fish and shellfish species from increased turbidity.	See above.
NRW	2018 Scoping Comments	We welcome your indication in Table 11.1 that transitional fish species (such as bass, whiting and herring) will be considered as part of the wider fish assessment which will include consideration of seasonal variation in fish spawning and larval activity. The ES should differentiate between transitional and migratory fish assemblages where possible.	See above.

10.4. METHODOLOGY

10.4.1. Impact Assessment Methodology

18. The assessment approach has adopted the following stages:

- Review of existing relevant data and information;
- Formulation of a conceptual understanding of baseline conditions;
- Consultation and agreement with the regulators regarding proposed assessment approaches;
- Determination of the worst-case scenarios;
- Consideration of embedded mitigation measures; and
- Assessment of effects using data analysis, numerical modelling outputs, and expert-based judgements by MarineSpace Ltd.

19. A detailed description of the Impact Assessment Methodology is provided in **Chapter 5, EIA Methodology**. A short summary is provided here for completeness, with additional detail provided for the specific receptor of this chapter.

20. A Project Design Envelope approach, often referred to the ‘Rochdale Envelope’, has been used in this assessment. This approach “defines a series of realistic maximum extents and magnitudes for the description of a development, so that a realistic ‘worst case scenario’ is assessed”. **Chapter 4, Project Description**, sets out the parameters of the project in order to complete the assessment.

21. Effects are changes in the physical environment that may arise during Project activities. Effects can result in impacts where a receptor is sensitive to them. Impacts can be considered as direct, indirect, inter-relationships, or cumulative (see **Chapter 5, EIA Methodology** for definitions).

22. The assessment of effects on fish and shellfish ecology is predicated on a Source-Pathway-Receptor (S-P-R) conceptual model, whereby the source is the initiator event, the pathway is the link between the source and the receptor impacted by the effect, and the receptor is the receiving entity.

23. An example of the S-P-R conceptual model is provided by cable installation which disturbs sediment on the sea bed (source). This sediment is then transported by tidal currents until it settles back to the sea bed (pathway). The deposited sediment could smother and have an effect on the species on this area of the seabed (receptor).

24. Consideration of the potential effects of the Project is carried out over the following spatial scales:

- Near-field: the area within the immediate vicinity (tens or hundreds of metres) of the project and along the export cable corridor; and
- Far-field: the wider area that might also be affected indirectly by the project (e.g. due to disruption of waves, tidal currents or sediment pathways).

25. The S-P-R approach has been used in order to provide systematic approach to "understanding the potential for effects to arise, the spatial extents of the effect-receptor interactions, impact pathways, and potential impact significance."

26. Three main phases of development are considered over the life-cycle of the Project, in conjunction with the present-day baseline. These are:

- Construction phase;
- Operation and maintenance phase (including repowering); and
- Decommissioning phase.

10.4.1.1. Sensitivity, Value and Magnitude

27. The determination of each aspect of the receptor (sensitivity, value, magnitude) was considered for each species, using available evidence, including published data sources, and expert judgement.

28. The sensitivity of the receptor was considered in terms of its:

- Tolerance to an effect (the extent to which the receptor is adversely affected by an effect);
- Adaptability (the ability of the receptor to avoid adverse impacts that would otherwise arise from an effect); and
- Recoverability (a measure of a receptor's ability to return to a state at, or close to, that which existed before the effect caused a change).

29. In addition, a value component may also be considered when assessing a receptor. This ascribes whether the receptor is rare, protected or threatened; has key life stages in the area; or is of commercial value, which is of particular relevance to fish and shellfish receptors. It is important to note that value does not necessarily imply greater sensitivity to effects.

30. The magnitude of an effect is dependent upon its:

- Scale (i.e. size, extent or intensity);
- Duration;
- Frequency of occurrence; and
- Reversibility (i.e. the capability of the environment to return to a condition equivalent to the baseline after the effect ceases).

31. The sensitivity and value of receptors and the magnitude of effect are assessed using available literature and data, expert judgement, and also published sensitivity assessments on the Marine Life Information Network (MarLIN) (2019). Definitions for each term are provided in **Table 10-4** to **Table 10-6**. These expert judgements of receptor sensitivity, value and magnitude of effect are guided by the conceptual understanding of baseline conditions.

Table 10-4 Definitions of the Sensitivity Levels for Fish and Shellfish Receptors

Sensitivity	Definition
High	Tolerance: Receptor has very limited tolerance of effect Adaptability: Receptor unable to adapt to effect Recoverability: Receptor unable to recover resulting in permanent or long-term (greater than ten years) change
Medium	Tolerance: Receptor has limited tolerance of effect Adaptability: Receptor has limited ability to adapt to effect Recoverability: Receptor able to recover to an acceptable status over the medium term (5-10 years)
Low	Tolerance: Receptor has some tolerance of effect Adaptability: Receptor has some ability to adapt to effect Recoverability: Receptor able to recover to an acceptable status over the short term (1-5 years)
Negligible	Tolerance: Receptor generally tolerant of effect Adaptability: Receptor can completely adapt to effect with no detectable changes Recoverability: Receptor able to recover to an acceptable status near instantaneously (less than one year)

Table 10-5 Definitions of the Value Levels for Fish and Shellfish Receptors

Value	Definition
High	Receptor is designated and/or of national or international importance. Likely to be rare. Has been identified as having a key life stage (spawning or nursery ground) that overlaps the MDZ Is of significant commercial importance (i.e. regularly landed from the area, as revealed by local fishermen or ICES data)
Medium	Receptor is not designated but is of local to regional importance. Has been identified as having a key life stage in the greater region, but not directly overlapping the MDZ The receptor has been landed but not on a regular basis
Low	Receptor is not designated but is of local importance
Negligible	Receptor is not designated and is not deemed of importance

Table 10-6 Definitions of Magnitude of Effect for Fish and Shellfish Receptors

Magnitude	Definition
High	Scale: A change which would extend beyond the natural variations in background conditions Duration: Change persists for more than ten years Frequency: The effect would always occur Reversibility: The effect is irreversible
Medium	Scale: A change which would be noticeable from monitoring but remains within the range of natural variations in background conditions Duration: Change persists for 5-10 years Frequency: The effect would occur regularly but not all the time Reversibility: The effect is very slowly reversible (5-10 years)

Magnitude	Definition
Low	Scale: A change which would barely be noticeable from monitoring and is small compared to natural variations in background conditions Duration: Change persists for 1-5 years Frequency: The effect would occur occasionally but not all the time Reversibility: The effect is slowly reversible (1-5 years)
Negligible	Scale: A change which would not be noticeable from monitoring and is extremely small compared to natural variations in background conditions Duration: Change persists for less than one year Frequency: The effect would occur highly infrequently Reversibility: The effect is quickly reversible (less than one year)

10.4.1.2. Impact Significance

32. Following the identification of receptor sensitivity and value, and magnitude of effect, it is possible to determine the significance of the impact. A matrix is presented in **Table 10-7** as a framework to guide how a judgement of the significance is determined. The matrix approach ensures a consistent approach and limits the subjectivity of the impact assessment arising from expert judgement.

33. Through use of the matrix shown in **Table 10-7** an assessment of the significance of an impact can be made in accordance with the definitions in **Table 10-8**.

Table 10-7 Impact Significance Matrix

		Negative Magnitude				Beneficial Magnitude			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

Table 10-8 Impact Significance Definitions

Value	Definition
Major	Very large or large change in receptor condition, either adverse or beneficial, which are likely to be important at a population (national or international) level because they contribute to achieving national or regional objectives, or, could result in exceedance of statutory objectives and / or breaches of legislation.
Moderate	Intermediate change in receptor, which may to be important considerations at a regional population level.
Minor	Small change in receptor condition, which may be raised as local issues but are unlikely to be important at a regional population level.
Negligible	No discernible change in receptor condition

34. For the purposes of this ES, ‘major’ and ‘moderate’ impacts are deemed to be significant (in EIA terms). In addition, whilst ‘minor’ impacts may not be significant, it is important to distinguish these from other non-significant (negligible) impacts as they may contribute to significant impacts cumulatively.

10.4.1.3. Cumulative Impact Assessment

35. Impact inter-relationships are given consideration in this chapter. These can be defined as the potential for different residual impacts to have a combined impact on key sensitive receptors.

36. Cumulative impacts are assessed through consideration of the extent of influence of changes to fish and shellfish ecology arising from the project alone and those arising from the project cumulatively or in combination with other reasonably foreseeable plans and projects.

10.4.2. Study Area

37. The Project area is delineated by the Offshore Development Area (OfDA) for consent which offshore includes the Morlais Demonstration Zone (MDZ) and the export cable corridor (ECC; **Figure 1-1, Volume II**). The MDZ comprises 35 km^2 and the ECC 4.75 km^2, (including an intertidal area of 0.01 km^2) totalling an area of 39.75 km^2 for the RLB. The RLB extends westward from the west coast of Holy Island, Anglesey, Wales. At the nearest point the MDZ lies approximately 0.5 km from the coast, with the farthest point approximately 7 km from the coast. The ECC lies to the east of the MDZ, between it and the coast.

38. The study area for the purpose of this chapter is defined as the boundary of ICES Statistical Rectangle 35E5, within which the MDZ and ECC are located. The boundaries of ICES Statistical Rectangle are shown in **Plate 10-1**.

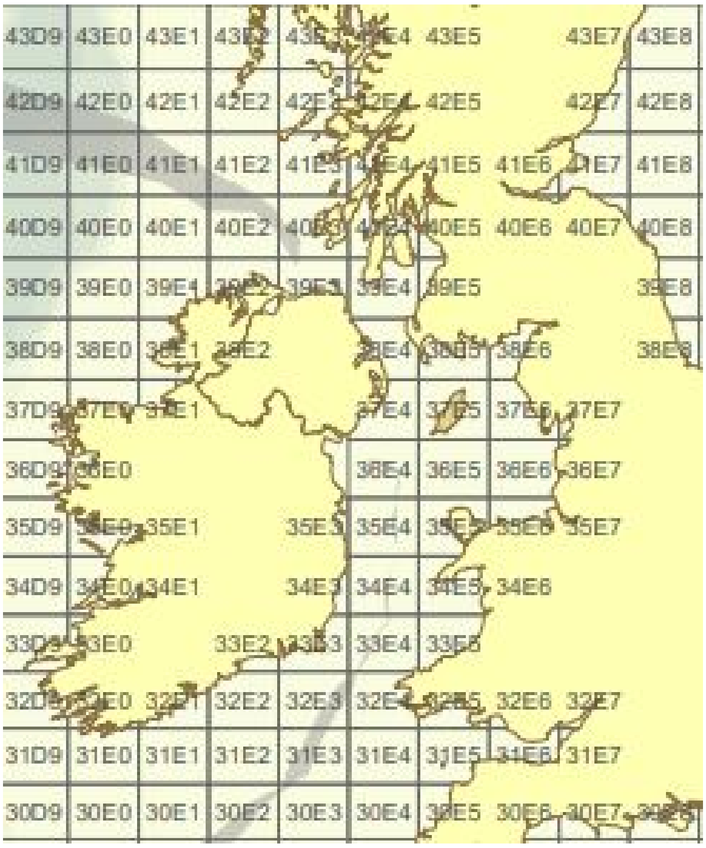

Plate 10-1 The ICES Statistical Rectangles in the Irish Sea

39. This study area lies within the greater Irish Sea West Functional Unit 15, in Division VIIa (Irish Sea), within subarea VII. The area is described in terms of its baseline environment of the fish

and shellfish community, with particular note of species that have key life stages in the area, or those that are of commercial or conservation importance. Where more fine-scale/local information is available, these have been used to supplement the knowledge at the study area scale.

40. The migratory fish community was characterised at a regional scale with their distribution based upon knowledge of their presence in rivers that lead into the Irish Sea (see **Document MOR/RHDHV/DOC/0067, Information to Support HRA,** for more details).

10.4.3. Data Sources – Desk Study

41. The primary resources used to inform this chapter include:

- Marine Life Information Network (MarLIN);
- SeaLifeBase and FishBase;
- SharkTrust;
- National Biodiversity Network (NBN) Atlas;
- ICES landings data;
- IUCN Red list;
- Relevant nature conservation legislative documents;
- Consultation responses; and
- Published and unpublished literature.

10.4.4. Data Sources – Site-Specific Surveys and Reports

42. No site-specific surveys for fish and shellfish were conducted for the Project. Based on the nature of the area and likely (low level of) impacts on fish species it was determined that site-specific surveys were not required. This approach follows the clear precedent set by offshore energy developments in recent years.

43. Although not directly related to fish, one site-specific survey conducted for the Project was used to inform this chapter (detailed results are presented in **Chapter 9, Benthic and Intertidal Ecology**):

- Ocean Ecology, 2018. MDZ Benthic Ecology Characterisation Survey 2018.

10.5. EXISTING ENVIRONMENT

44. The distribution of fish and shellfish is influenced by abiotic and biotic factors. Abiotic factors, those that characterise the physical environment, can include water temperature, salinity, nutrient levels, water depth, bathymetry, hydrographic regime, substrate and physical habitat. Biotic factors, those that characterise the biological environment, can include food availability, predator-prey interactions, competition and human activities.

10.5.1. Physical Environment

45. The study area lies within the eastern Irish Sea. The bathymetry of the Irish Sea is defined by a deep (up to 150 m) channel orientated north-south in the western part (Parker-Humphreys, 2004). This channel forms a boundary at the western edge of the extensive, shallow coastal shelf upon which the Project is located. The channel is thought to play an important role in the ecology of the demersal fish in the area, creating a divide between populations and consequent differences in their life history traits, and also allowing for the occurrence of deep-water fish from the Celtic and Sea and north-west Scotland.

46. The circulation of the Irish Sea is characterised by an overall south-to-north flow, passing to the west of the Isle of Man (Parker-Humphreys, 2004). The eastern Irish Sea, off the coast of North Wales, is dominated by an anti-clockwise gyre, which entrains water from south to north, along the north-west coast of Wales.

47. There are several seasonal fronts within the Irish Sea. In spring, a strong front develops in the western Irish Sea close to Ireland, keeping the mixed waters to the southeast (including the Project) separate from the stratified waters to the northwest. Local seasonal fronts may also develop in the eastern Irish Sea near Liverpool (to the east of the Project), and in Cardigan Bay (to the south of the Project).

48. The site-specific physical characteristics are detailed in **Chapter 7, Metocean Conditions and Coastal Processes**. Within the MDZ, water depth ranges from 2 m at the landfall and up to 72 m in the northwest part. The average depth is approximately 40 m. Most of the seabed comprises large areas of outcropping bedrock with minimal relief above surrounding bed levels. There is a sand ridge north of South Stack that extends northwards for approximately 1 km. The seabed is uneven at a local scale due to the presence of bedforms of a variety of size.

49. Tidal conditions are characterised as having a typical spring tidal range of around 4.5 m and a typical neap tidal range of around 3.0 m. There are very high baseline current speeds (>2 m/s) in the MDZ. Dominant wave conditions in the MDZ are from south-southwest to southwest. Dominant sediment type is gravel or gravelly sand in the MDZ.

10.5.2. Biological Environment

50. Food availability is an important factor in determining the distribution of fish and shellfish. Certain species are mobile and so able to forage large distances for food, whereas others remain in one area and so are reliant upon the environment at that location for food. Important food sources to fish and shellfish can range from plankton, for shellfish and small species including juvenile life stages, through to animals larger than themselves (cetaceans, sharks) for parasitic species such as lamprey.

51. Fish and shellfish are an important food source for many species in the area. Species that may predate on fish include other fish, birds, and cetaceans. As detailed in **Chapter 12, Marine Mammals**, the diet of the most common marine mammal species in the area (harbour porpoise, bottlenose dolphin, grey seal) is comprised mostly of fish, with crustaceans also important. Species such as herring, sprat and sandeel are key prey items of several marine ornithology receptors, as stated in **Chapter 11, Marine Ornithology**.

52. As fish and shellfish can comprise both prey and predators to certain species, there will be competition with identified species occupying the same trophic level. Furthermore, they may be competition for habitats for sessile species.

53. The biological habitats present in the greater region are outlined in **Chapter 9, Benthic and Intertidal Ecology**. In summary, the intertidal areas around Anglesey are extensive areas of relatively undisturbed habitats comprised of high energy rocky shores, sea cliffs, coastal heathlands and coastal grazing. The west of Anglesey, where the export cable will make landfall, has substantial areas of exposed shores which are largely coastal cliff headlands with beaches comprise of moderate coarse sediments. The benthic communities around the Project are typically common in the Anglesey area and the wider Welsh coastal regions. These communities are typically comprised of common polychaetes, crustaceans, molluscs and echinoderms.

54. Human activities may cause effects in the area that can potentially lead to impacts upon fish and shellfish species. This includes fishing activity, aquaculture, extraction and deposition activities, and development. Furthermore, human-induced climate change may affect the future distribution and production of the fish and shellfish resource.

55. Fisheries are a particularly important extractive activity in the area, as detailed in **Chapter 14, Commercial Fisheries.** The most common fishing activity in the MDZ utilises static fishing gear, particularly pots, targeted towards catching crab/lobster and whelks. Otter trawls for scallop species are also common in the deeper waters that surround the MDZ, within the study area.

56. The important biological factors of the receptor species that need to be taken into consideration include the distribution in the study area, with particular reference to the occurrence of key areas such as spawning, nursery or feeding grounds or migratory routes and any overlap with the MDZ.

57. The occurrence of the receptor species in the study area needs to be considered in terms of temporal and spatial patterns. Value of the species, in terms of conservation or commercial importance, is also determined.

58. The Irish Sea is utilised by species of migratory fish that spend part of their life cycle in the marine environment as well as the freshwater environment. Rivers that lead to the Irish Sea and have known populations of such migratory fish species are considered as part of the biological environment that can be influenced by the Project.

10.5.3. Fish and Shellfish Species Present

59. In order to establish the fish and shellfish present in the area a range of resources were used. An overview of the data from commercial fisheries is presented below, though a more in-depth analysis can be found in **Chapter 14, Commercial Fisheries**. Commercial fisheries data is not necessarily representative of the species present in an area, as the species landed are targeted using selective gear types and are predominantly driven by demand. Therefore, information has been sourced from published and grey literature reports, including surveys from nearby developments, to supplement commercial data.

10.5.3.1. Commercial Fisheries

60. Fisheries landing data from ICES Rectangle 35E5 for the period 2013-2017 (MMO, 2018) was used to determine the presence and relative importance of commercial fish and shellfish species. Shellfish species are the highest group by landed weight, of which whelks *Buccinium undutam* are the most landed at 170 tonnes and also the most valuable, worth nearly £5,000,000 from 2013-2017. Other commercially important shellfish species include crabs, lobsters, prawns, scallops, and specifically queen scallops *Aequipecten opercularis*, all of which had more than 50 tonnes landed from 35E5. Bass *Dicentrarchus labrax* are the by far the most landed fin fish at 60 tonnes, with cod *Gadus morhua*, flounder *Platichthys flesus*, mackerel *Scomber scombrus*, mullet species, plaice *Pleuronectes platessa*, pollack *Pollachius pollachius*, and thornback ray *Raja clavata* of minor commercial importance (10-20 tonnes landed).

61. Fishing activity in the MDZ, as indicated by local fishermen, is dominated by static gear, which are used to target shellfish species including crab (velvet and green shore), lobster, whelk and scallop. Prawns also feature highly in the MMO landings data (MMO, 2018), as well as bass. Skate were also highlighted as a key species during consultation. There is generally no pelagic fishing due to no quotas being available to fish species here.

10.5.3.2. Published Literature

62. The Irish Sea has a diverse fish community. Over 170 species of marine fish have been recorded in the area (Ellis et al., 2002). CEFAS beam trawls between 1993-2001 recorded over 100 species (Parker-Humphreys, 2004). Both of these species counts were based upon survey data taken from a spatial scale greater than the survey area. However, these have been used as there is no data at a more fine-scale resolution that contains the MDZ.

63. The fish surveys conducted between 2010-2015 as part of the Horizon Nuclear Power (HNP) development identified 96 unique species through their range of survey methods (HNP, 2018a). These surveys occurred off north Anglesey, wholly within ICES Statistical Rectangle 35E5. The data acquired are considered a good representation of the study area.

64. The Irish Sea contains several distinct assemblages of pelagic and demersal fish. There are three types of demersal fish assemblage, and four types of generic fish assemblage. The study area is characterised as having an inshore demersal assemblage, dominated by plaice, dab and sole, as revealed by otter trawls (Ellis et al., 2002). The MDZ is likely to have traits of the “eastern inshore” fish assemblage, based on depth, although there were no surveyed sites nearby. Little seasonal variation is reported for these assemblages (Ellis et al., 2002). Note that the surveys used for gathering this data are aimed at sampling commercially important species, and so do not sample large pelagic or littoral species, but are still very useful (Ellis et al., 2002).

65. Each of the species identified as overlapping the Project needs to be assessed for its protected status as well as the presence of any spawning, nursery or feeding grounds for the impact assessment. The sources used to identify these parameters are described below.

10.5.3.3. Species and Habitats of Conservation Importance

66. Certain fish and shellfish species found in the area have been given protection measures due to their nature conservation status. The protection measures and the relevant fish and shellfish they protect are listed below:

- Habitats Directive – under this Directive Special Areas of Conservation (SAC) are designated for protected habitats and species. Designated migratory fish species on Annex II of the Directive that are found in the region include sea lamprey *Petromyzon marinus*, river lamprey *Lampetra fluviatilis*, allis shad *Alosa alosa*, twaite shad *Alosa fallax*, and Atlantic salmon *Salmo salar*. All five species are interest features of nearby SACs;
- UK Post-2010 Biodiversity Framework (this replaces the earlier UK Biodiversity Action Plan (BAP)) - species which are of principal importance under this designation include those of commercial importance such as plaice, whiting and Dover sole, as well as rare species, such as some elasmobranchs and shellfish;
- Marine Conservation Zones (MCZ) – these focus on threatened, rare or declining habitats and species. One marine site in Wales has been designated as an MCZ, specifically around Skomer Isles in south-west Wales. A further 6 sites have been recommended as MCZs in offshore Welsh waters (beyond 12 nm) (Royal Yachting Association (RYA), 2019), of which the nearest to the site may be approximately 12 nm
- The OSPAR Convention - this Convention provides legislative protection for commercially exploited and ecologically vulnerable species such as cod, sea lamprey and European eel, all of which are found in the region. OSPAR has established a list of threatened and/or declining species and habitats in the north-east Atlantic. The list provides an overview of the biodiversity in need of protection and is being used by the OSPAR Commission to guide priorities for further work on the conservation and protection of marine biodiversity;
- Wildlife and Countryside Act, 1981 – Schedule 5 of this Act lists species that are afford legal protection from intentional harm. Species on the list that are found in the area include shad, basking shark, angel shark, and seahorses;
- Natural Environment and Rural Communities Act 2006 – this Act was designated to help achieve a rich and diverse natural environment as well as improving rural communities. Sections 41 and 42 of this Act lists species of principal importance to achieve this goal. Note that this legislative instrument has been replaced in Wales by the Environment (Wales) Act 2016 though the list remains the same; and
- Common Fisheries Policy (CFP) zero Total Allowable Catch (TAC) species – there are certain species which are not allowed to be landed commercially under the CFP. This includes key species such as European eel and the rarer elasmobranch species.

10.5.3.4. Spawning and Nursery Grounds

67. The presence of spawning and nursery grounds for different fish and shellfish species in the area were identified using the following sources: Pawson and Robson (1996), Coull et al. (1998), Ellis et al. (2012), and Aires et al. (2014). The location of spawning and nursery grounds for different fish species that are in the vicinity of the study area are presented in **Figures 10-1**, **10-2**, and **10-3** (**Volume II**).

68. In summary, the MDZ overlaps important spawning and nursery grounds for many fish species. The MDZ lies within a nursery area for anglerfish (**Figure 10-1, Volume II**). Cod, mackerel, sandeel and sole also have nursery areas that overlap the MDZ, with spawning grounds also nearby (~20 km away) (**Figures 10-1** and **10-2, Volume II**). The MDZ overlaps both spawning and nursery areas for spotted ray and whiting (**Figures 10-2** and **10-3, Volume II**). Tope shark and plaice spawning grounds overlap the MDZ, and plaice also has a nursery area nearby (~20 km) (**Figures 10-1** and **10-3, Volume II**). Thornback ray have spawning areas near (~20 km) the MDZ (**Figure 10-3, Volume II**).

10.5.4. Elasmobranchs

69. The study area is been defined as the ICES Statistical Rectangle 35E5. The presence of elasmobranch species within this study area was determined using several sources: ICES landings from region 35E5 (MMO, 2018), ICES factsheet for region VII (FAO, 2008), National Biodiversity Network (NBN) Atlas (NBN, 2019), and the Horizon Nuclear Power (HNP) report on fish and shellfish (HNP, 2018a).

70. According to the FAO (2008) the elasmobranchs in region VIIa include: thornback ray *Raja clavata,* spotted ray *Raja montagui*, blonde ray *Raja brachyura*. Fish surveys conducted around the north of Anglesey (HNP, 2018a) also confirm bull huss *Scyliorhinus stellaris*, spurdog *Squalus acanthias*, and tope *Galeorhinus galeus*. The NBN Atlas also list additional elasmobranch species with recorded presence (two or more confirmed records) in the study area, including: undulate ray *Raja undulata*, lesser-spotted dogfish *Scyliorhinus canicula*, and basking shark *Cetorhinus maximus*.

71. Common skate *Dipturus batis-c*omplex was historically distributed throughout the continental shelf waters of the north-east Atlantic, however it has declined severely in the Irish Sea, with only very occasional records reported (International Union for Conservation of Nature (IUCN), 2019). There is one record of this species in the area on the NBN Atlas, though this was obtained in 1983 (NBN Atlas, 2019). As a precautionary measure, due to its nature conservation status, this species has been included as part of the baseline community.

72. Similar to common skate, the angel shark *Squatina squatina* originally ranged across the continental shelf waters of northeast Atlantic, however now its presence is almost completely limited to the Canary Islands (IUCN, 2019). There exists one historic record off Anglesey in 1992 on the NBN Atlas. However, recent records of catches have been recorded off Wales (Angel Shark Project, 2019). Due to recent records in the study area, this species has been included as part of the baseline community.

73. Elasmobranch species that have confirmed presence in the study area have been described in terms of their ecology in **Table 10-9**.

74. It should be noted that many of these species would not be expected to be encountered in the MDZ due to absence of suitable habitat. Many elasmobranch species, particularly the skates, rays and angel shark, prefer soft bottoms, which are not found in the MDZ. Only the two *Scyliorhinus* species have habitat preferences that may align with the habitats present in the MDZ. Other more benthopelagic species, with less habitat preference (spurdog, tope, and basking shark), typically inhabit deeper waters with the shallow waters of the MDZ representing the upper limit of their range. .

Table 10-9 Important Elasmobranch Species Present in the Study Area and their Ecology

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
Thornback ray	Overwinters in deeper water, migrating into shallower areas in the late spring and summer (February-September) to spawn.	Inhabits continental shelf and upper slope waters from 10-300 m, though it is most abundant in waters 10-60 m. Frequents a range of sediments, though not typically coarser sediments.	Mostly non-migratory, though fish often moves close inshore during the spring.	Adults feed on large crustaceans and small teleost fish such as sandeels, small gadoids and dragonets, whereas juveniles prefer small crustaceans.	SharkTrust, 2019 MarLIN, 2019
Spotted ray	Limited information on the reproductive biology of this species	Majority of population found in waters 100-500 m deep. Prefers soft, sandy substrates in coastal seas and on continental shelves	Mostly non-migratory, though females migrate to shallow waters from April-July to spawn.	Adults feed on large crustaceans, teleost fish, polychaetes and molluscs, juveniles on small crustaceans.	SharkTrust, 2019 MarLIN, 2019
Blonde Ray	Spawning occurs between February and August.	Varied depth range depending on location, up to 150 m in NE Atlantic, 10-300 m in Mediterranean, and globally up to 900 m. Typically occurs on soft substrate such as sandy and muddy ground.	Shallow, coastal waters are used as nursery areas, leading to an increased presence of juveniles.	Both adults and juveniles feed on crustaceans, with larger adults also taking cephlapods and small teleosts.	SharkTrust, 2019 MarLIN, 2019
Common skate complex	Mating occurs in spring, followed by spawning in summer.	Lives on sandy and muddy bottoms, at depths of 10-600 m.	Juveniles prefer shallow waters.	Actively hunts other elasmobranchs, teleosts, cephlapods and crustaceans.	SharkTrust, 2019 MarLIN, 2019
Undulate ray	Breeding occurs between March and June	The species occurs at a range of depths, from 10-200 m. It prefers sandy substrate	Unknown	Varied diet depending on age. Young feed on crustaceans, molluscs and small fish, whereas adults specialise in crustaceans only	SharkTrust, 2019 MarLIN, 2019
Lesser-spotted dogfish (aka smallspotted catshark)	Egg-laying occurs during spring and early summer	Found from shallow sublittoral waters up to 400 m, mostly on sand and mud, but also on algae, rocky and gravelly bottoms	Females come inshore during the warmer months to lay eggs	It feeds opportunistically on a range of benthic fauna, mostly crustaceans and molluscs. Feeding intensity is highest during the summer	SharkTrust, 2019
Greater spotted dogfish (aka	Spring and summer are when egg-laying occurs	Found at depths of up to 125 m but most common between 20-63 m.	Shallow waters are used for egg-laying. The Llŷn	Take a variety of prey, mostly crustaceans, but also molluscs, small teleosts and *S. canicula*	SharkTrust, 2019 MarLIN, 2019

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
nursehound, bull huss)		Prefers rough, rocky or coralline grounds with algal cover	Peninsula is thought to be important		
Angel shark	Birthing occurs in July in this region	Inhabits coasts and estuaries, in waters of 5-150 m depth. Buries itself in the substrate during the day, active at night	Migratory in this region, moving north during summer, and south during winter	Diet comprises mostly bony fish, especially flatfish, and also skates, crustaceans, and molluscs	SharkTrust, 2019
Spurdog (aka spiny dogfish)	Timing of reproduction varies by location, though it broadly occurs between January-August	Found in inshore waters to continental shelf, most commonly 10-200 m but recorded up to 900 m. Is epibenthic but also occurs in water column, with no preference for habitat	Highly migratory, dependent on age and sex. Young females migrate to shallow waters to give birth	In this region their diet is mostly teleost fish (herring, whiting, Norway pout, cod, and Atlantic mackerel), with crustaceans often taken by smaller individuals	SharkTrust, 2019
Tope	Mating and partuition occurs during the spring	Found inshore through to 550 m depth, mostly near the seabed	Highly migratory in this region, moving north in the summer, and south in the winter. Females give birth in shallow waters	Feeds mostly on a wide variety of teleost fish, in addition to some invertebrates	SharkTrust, 2019
Basking Shark	Very little is known	Occurs mostly offshore but does venture into shallows near shore	Unknown	Passive filter feeder, feeding solely on plankton	SharkTrust, 2019

10.5.4.1. Commercial Importance

75. Commercially important elasmobranch species which are landed from ICES Statistical Rectangle (Rectangle) 35E5 (the study area) include lesser spotted dogfish and thornback ray. Other species of elasmobranch may also be caught, but not routinely identified to species when landed.

10.5.4.2. Spawning and Nursery Grounds

76. Of note is that the Project area overlaps with the spawning areas of tope shark and both the spawning area and nursery area of spotted ray. There are also spawning areas of thornback ray in the study area (nearest distance from the MDZ is 20 km).

10.5.4.3. Conservation Importance

77. The designated status of each of the species on the short list is listed in **Table 10-10**. The majority of elasmobranch species, specifically all but the two *Scyliorhinus* species, present in the study area are listed under nature conservation protection measures. Few of the elasmobranch species are of Least Concern; almost all have a greater threatened status according to the IUCN (2019). There are several species for which commercial landings are prohibited, in that they have a zero Total Allowable Catch (TAC) under the Common Fisheries Policy (CFP) (ICES, 2019).

78. In addition, the undulate ray is also an MCZ Feature of Conservation Importance (FOCI) species (Joint Nature Conservation Committee (JNCC), 2016).

Table 10-10 Nature Conservation Status of Elasmobranch Species Found Within the Study Area

Common Name	Nature Conservation Status							
	IUCN Red List	OSPAR Annex V (list of species threatened and / or in decline)	NERC Act 2006 Section 41 (England)	Environment Act Section 7 (replaced NERC Act Section 42 (Wales))	UK Biodiversity Action Plan (BAP)	UK Wildlife and Countryside Act 1981 Schedule 5	Habitats Directive	Common Fisheries Policy zero TAC species
Thornback ray	Near Threatened	Yes[1]	No	Yes	No	No	No	No
Spotted ray	Least Concern	Yes	No	No	No	No	No	No
Blonde Ray	Near Threatened	No	No	Yes	No	No	No	No
Common skate	Critically Endangered (A2bcd+4bcd)	Yes	Yes	Yes	Yes	No	No	Yes
Undulate ray	Global: Endangered (A2bd+3d+4bd) Europe: Near Threatened	No	Yes	Yes	Yes	No	No	Not assessed
Lesser-spotted dogfish (aka small spotted catshark)	Least Concern	No	No	No	No	No	No	Not assessed
Greater spotted dogfish (aka nurse hound, bull huss)	Near Threatened	No	No	No	No	No	No	Not assessed
Angel shark	Critically Endangered (A2bcd+3d)	Yes	No	Yes	Yes	Yes[2]	No	Yes
Spurdog (aka spiny dogfish)	Global: Vulnerable (A2bd+3bd) Europe: Endangered (A2bd)	Yes	Yes	Yes	Yes	No	No	Yes[3]

Common Name	Nature Conservation Status							
	IUCN Red List	OSPAR Annex V (list of species threatened and / or in decline)	NERC Act 2006 Section 41 (England)	Environment Act Section 7 (replaced NERC Act Section 42 (Wales))	UK Biodiversity Action Plan (BAP)	UK Wildlife and Countryside Act 1981 Schedule 5	Habitats Directive	Common Fisheries Policy zero TAC species
Tope	Vulnerable (A2bd+3d+4d)	No	No	Yes	Yes	No	No	No
Basking shark	Vulnerable (A2ad+3d)	Yes	Yes	Yes	Yes	Yes	No	Yes

1: Thornback ray is listed as under threat and / or in decline in OSPAR Region II (the Greater North Sea), which is outside the area.

2: Angel shark is only protected between 0 and 6 nautical miles; this protection does not apply to territorial waters between 6 and 12 nm.

3: Vessels are allowed to land spurdog as bycatch so long as they are part of a bycatch monitoring programme.

10.5.5. Demersal Fish

79. The fish community of the study area comprises mostly demersal fish species.

80. A “long list” of all potential species in the study area was created. The sources that informed this long list were Ellis et al. (2002) and the HNP report (2018a). The long list was then refined to a short list that only included species with preferences for habitat that can be found within the MDZ (based on depth and sediment type). The list was further refined by only including species of nature conservation, key life stages and/or commercial importance. The demersal fish species present on this short list are given in **Table 10-11**.

10.5.5.1. Commercial Importance

81. There are many species of demersal fish that were landed from ICES Rectangle 35E5 between 2013-2017 (MMO, 2018). Such species include bass, brill, cod, conger eel, dab, flounder, gurnards, haddock, john dory, lemon sole, ling, monkfish, mullet species, plaice, pollock, sole, turbot and whiting.

82. The area lies within a Bass Fishing Restricted Area for both recreational and commercial fisheries (MMO, 2019). For the 2019 season, only one individual seabass may be landed per recreational fisherman per day in the period 1st April to 31st October. Dependent on findings of future bass stock assessments, this restriction may be removed or revised in future years.

10.5.5.2. Spawning and Nursery Grounds

83. Of note is that the MDZ partially overlaps with nursery grounds for anglerfish, cod, sandeel, sole, and whiting. It also overlaps spawning grounds for plaice and whiting.

10.5.5.3. Conservation Importance

84. Within the demersal fish species identified as having potential presence in the MDZ (**Table 10-11)** there are many species which are protected under various nature conservation measures (**Table** 10-12). These include whiting, cod, anglerfish, hake, halibut and ling. There are several species with a threatened status according to the IUCN (2019). Only whiting are a zero TAC species under the CFP.

Table 10-11 Important Demersal Species with Likely Presence in the MDZ and their Ecology

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
Whiting	Spawning occurs January-September	Depth range 10-200 m, most commonly 30-100 m, over mud and gravel bottoms mostly, but also on sand and rock	Individuals migrate to open sea after first year	Feed on a range of benthic prey	FishBase (2019) IUCN (2019)
Tub gurnard	Spawns from May to July	Occurs at depth ranges of 20-318 m, on sand and gravel habitats	Unknown, though increase in number over wintering in North Sea	Fish, crustaceans and molluscs are prey	FishBase (2019) Seafish (2010)
Grey gurnard	Spawns April to August	Common on sand, rocky and muddy bottoms between coastal and 140 m depth	Unknown	Feeds on crustaceans and fish	FishBase (2019) Seafish (2010)
Cod	Spawning occurs in winter and beginning of spring	Juveniles prefer shallower waters (10-30 m) with complex habitats than adults (up to 600 m)	Migrate between spawning, feeding and overwintering areas, journeys of <200 km	Omnivorous, feeding on mostly fish and invertebrates	FishBase (2019)
Angler/monkfish	Spawning occurs between January and June	Occur at depths from coast up to 1,000 m, on sandy and muddy bottoms. May also be found on rocky bottoms	Migrate between inshore and offshore spawning grounds	Feeds mostly on fish that it lures	FishBase (2019) IUCN (2019)
European hake	Spawning occurs April-December, with a peak in February-March	Found usually between 30-1075 m, normally 70-400 m	Diurnal; off bottom during day, on bottom at night	Feed mainly on fish, with young feeding on small crustaceans	FishBase (2019) IUCN (2019)
Brill	Spawning occurs in first half of year, varies by location	Live on sandy or mixed bottoms up to 50 m	Adults found more offshore than juveniles	Feed on benthic fish and crustaceans	FishBase (2019) IUCN (2019)
Red gurnard	Spawns in summer	Found over sand, gravel and rock between 15-400 m	Unknown	Feeds mostly on benthic crustaceans and fish	FishBase (2019) Seafish (2010)
Turbot	Spawning season is April-August	Most common on sandy, rocky or mixed bottoms. Depth range 20-70 m	Unknown	Feeds mostly on benthic fish and less on crustaceans and bivalves	FishBase (2019)
Golden grey mullet	Spawn between July-November	Prefers coastal waters including estuaries	Juveniles move inshore in spring and winter	Feed on small benthic organisms	FishBase (2019)

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
Thin-lipped grey mullet	Spawn between September-February	Shallow water species (10-20 m)	Adults spawn at sea but spend most of the time in estuaries	Feed on algae and plankton	FishBase (2019)
Thick-lipped grey mullet	Spawns pelagic eggs in February-April	Prefers inshore waters	Move northward during summer due to temperature rises. Juveniles move between inshore and sea	Feed mostly on benthic plant matter and small invertebrates	FishBase (2019) IUCN (2019)
Bass	Spawning occurs in spring	Inhabit coastal waters up to 100 m on range of bottom types	Migrate from coastal to offshore waters in winter	Feeds mostly on shrimp and molluscs, as well as fish	FishBase (2019)
Conger eel	Spawn in summer	Found on rocky and sandy bottoms between 0-500 m	Moves to deeper waters as it matures	Feeds on fish, crustaceans and cephalopods at night	FishBase (2019)
John Dory	Spawning occurs at the end of winter/early spring	Remains near seabed	Unknown	Feeds mostly on teleosts, also cephalopods and crustaceans	FishBase (2019)
Ling	Spawn in spring	Occurs mostly in deep water (100-400 m) over rocky bottoms	Unknown	Feeds on large fish and invertebrates	FishBase (2019) IUCN (2019)
Pollack	Spawn in the late winter to spring	Found from nearshore to 200 m, over hard bottoms	Larger individuals move to more open sea. May take spawning migrations	Major predator of young cod	FishBase (2019)
Red mullet	Spawning occurs in May-July	Occurs mostly at depths up to 100 m over hard broken grounds	Adults migrate to shallows in spring/summer; juveniles move summer/autumn	Feeds mostly on benthic invertebrates	FishBase (2019) IUCN (2019)
Sand sole	Unknown	Occurs at depths usually 20-50 m. Found on gravel, sand or mud	Unknown	Feeds on a wide range of crustaceans, mostly bivalves	FishBase (2019) IUCN (2019)
Halibut	Spawn December-April	Lives mostly at sea bottom, depth range of 50-200 m. Occurs on sand, gravel or clay bottoms. Spawning over soft sediment	Unknown	Mostly feeds on other fish, also other benthos	FishBase (2019) IUCN (2019)

Table 10-12 Nature Conservation Status of Demersal Fish Species Found Within the Study Area

Common Name	Nature Conservation Status							
	IUCN Red List	OSPAR Annex V (list of species threatened and / or in decline)	NERC Act 2006 Section 41 (England)	Environment Act Section 7 (replaced NERC Act Section 42 (Wales))	UK Biodiversity Action Plan (BAP)	UK Wildlife and Countryside Act 1981 Schedule 5	Habitats Directive	Common Fisheries Policy zero TAC species

10.5.6. Pelagic Fish

85. Four species of pelagic fish were identified as part of the ‘eastern inshore assemblage’ of the Irish Sea by Ellis et al. (2002). These were sprat *Sprattus sprattus*, herring *Clupea harengus*, Atlantic mackerel *Scomber scombrus* and horse mackerel *Trachurus trachurus*. Three of these species (not mackerel) were observed during the fish surveys as part of Horizon Nuclear development (HNP, 2018a).

86. Of these four species, herring and horse mackerel have designated status under protection measures. The Atlantic mackerel is the only species of pelagic fish which has been landed from ICES Rectangle 35E5 as sprat is not of conservation or commercial importance it is not considered further.

87. The ecology of the three pelagic species is presented in **Table 10-13**, and their nature conservation status presented in **Table 10-14**.

10.5.6.1. Spawning and Nursery Grounds

88. According to Pawson and Robson (1996), herring in the eastern Irish Sea have spawning grounds to the south of the Isle of Man and nursery grounds along the coastal, extending as far south as the north coast of Wales east of Anglesey. Neither of these are within 50 km of the study area. More recently herring has been assessed to have nursery grounds off the coast of Ireland (Coull et al., 1998; Aires et al., 2014) though again not overlapping the study area.

89. Mackerel is thought to spawn throughout the shelf waters of the UK (Pawson and Robson, 1996). The study area lies within a low intensity spawning ground, and there are low intensity nursery grounds in that adjacent ICES Rectangles to the north, which are approximately 20 km away (Ellis et al., 2012).

90. It is not possible to identify discrete spawning grounds for horse mackerel as juveniles are widespread (Ellis et al., 2012). Aires et al. (2014) indicate a patchy distribution of high probability of 0-group aggregations throughout the Irish Sea, including off north-west Wales.

Table 10-13 Important Pelagic Species Present in the MDZ and their Ecology

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
Atlantic herring	Comes to coastal areas to spawn. Both autumn and winter-spawning stock present	Occupy the water column from surface to 200 m depth	Comes to coastal areas to spawn	Feed mostly on small shrimps and copepods, with occasional filter-feeding	MarLIN (2019)
Horse mackerel	Spawning occurs in early spring for the "West stock"	Found on continental shelves (frequently over sandy bottoms) up to 500 m depth	Following spawning the stock migrates north to southern Norway/northern North Sea	Feeds on crustaceans, cephlapods and dfsh	IUCN Red List (2019) MarLIN (2019)
Mackerel	Spawning occurs during summer	Widely distributed on coastal shelves up to 200 m depth	Migrate in winter and early spring to spawning areas (inshore); spawn in summer; migration to post-spawning feeding grounds and overwinter areas	Filter-feeders on zooplankton, such as small fish and prawns	Angler's World (2014) MarLIN (2019)

Table 10-14 Nature Conservation Status of Pelagic Fish Species Found Within the Study Area

Common Name	Nature Conservation Status							
	IUCN Red List	OSPAR Annex V (list of species threatened and / or in decline)	NERC Act 2006 Section 41 (England)	Environment Act Section 7 (replaced NERC Act Section 42 (Wales))	UK Biodiversity Action Plan (BAP)	UK Wildlife and Countryside Act 1981 Schedule 5	Habitats Directive	Common Fisheries Policy zero TAC species
Herring	Least Concern	No	Yes	No	Yes	No	No	No
Horse mackerel	Global: Vulnerable (A2bd); Europe: Least Concern	No	Yes	No	Yes	No	No	No
Mackerel	Least Concern	No	Yes	No	Yes	No	No	No

10.5.7. Shellfish

91. The long list of shellfish species found in the area was determined from Pierce et al. (2005), landings data from ICES Rectangle 35E5, consultation with local fishermen, the scoping document (Royal HaskoningDHV, 2018), and the HNP (2018a) report. The long list was then narrowed down to species for which the MDZ presents suitable habitat, followed by those which are of nature conservation, commercial, or key life stage importance. The resultant short list of species and their ecology is presented in **Table 10-15.**

92. Clams, and specifically razor clams, are listed as a species landed from the area (ICES Rectangle 35E5). However, this common name can comprise multiple species therefore it was not possible to determine which species should be included. This is not of issue to the assessment as it is unlikely that clams would be present in the area due to the absence of suitable burying habitat in the MDZ.

10.5.7.1. Commercial Importance

93. Species of shellfish that have been landed from ICES Rectangle 35E5 between 2013-2017 are squid, crab (including specifically velvet swimming crab), European lobster, scallops (including specifically queen scallop), whelks, common prawns, and Norway lobster.

94. In addition, key shellfish species for the local area identified during consultation include crab (velvet and green shore), lobster, whelk, scallop and prawns.

10.5.7.2. Spawning/Nursery Area

95. The majority of shellfish species found in the area do no undertake migrations as they remain in one area throughout their life cycle. Some may undertake seasonal migrations to more inshore waters for spawning and nursery (specifically veined squid and common prawn). As the site is inshore it can be assumed that any shellfish species found in the area will be spawning in the area.

10.5.7.3. Nature Conservation Status

96. Most shellfish species are not designated under any protected measures. Indeed, most species are not even evaluated by the IUCN, and those that are considered of Least Concern (common cuttlefish, curled octopus, European lobster, and Norway lobster).

97. The only designated species found in the study area is the native or flat oyster *Ostrea edulis*. The NBN Atlas details accepted records of this species around the west coast of Anglesey, including off Holy Island (within 10 km). This species is designated under the NERC Act 2006 Section 41 (England), Environment Act Section 7 (replaced NERC Act Section 42 (Wales)), and UK Biodiversity Action Plan (BAP). It is also listed as threatened and / or in decline under OSPAR however only in the North Sea.

98. Although the species in themselves are not designated, both blue mussel beds (including intertidal beds on mixed and sandy sediments) and native oyster beds are designated as MCZ Habitat FOCI (JNCC, 2016). These have been recorded throughout the coast of Holy Island, including landward of the MDZ (NBN Atlas, 2019).

99. These two species have been recorded in the study area and are of conservation importance, therefore they are listed here for precautionary measures. However, it should be noted that these were not found in the MDZ area during the site-specific benthic survey (see **Chapter 9, Benthic and Intertidal Ecology**).

100. There are Shellfish Water Protected Areas in the coastal and brackish waters in Wales which are protected under the Water Framework Directive (NRW, 2018). There are six Shellfish Water Protected Areas around the coast of Anglesey., of which the nearest to the site is approximately 20 km to the south. More information can be found in **Chapter 8, Marine Water and Sediment Quality**.

Table 10-15 Important Shellfish Species with Likely Presence in the MDZ and their Ecology

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
European common squid	Spawning occurs intermittently over several months (season varies; in English Channel peak is late autumn/early winter)	Usually in the water column over sandy and hard bottoms. Occurs down to 200 m	Abundance varies	Squid feed upon fish, as well as crustaceans, polychaetes and other cephalopods	Pierce et al (2005) MarLIN (2019)
Brown crab	Mating takes place in spring and summer. Females are berried for 6-9 months, during which they remain in pits dug into the sediment or under rocks, not feeding. Larvae are released in late spring / early summer juveniles settle in the intertidal zone in late summer / early autumn.	Usually at depths between 6 m-40 m, but can be found offshore at depths of up to 100 m. Found on a range of substrates such as sand, gravel and rocky seabeds	Juveniles may remain in intertidal areas for approximately 3 years before moving to subtidal areas.	Crustaceans including smaller brown crabs as well as bivalve molluscs.	Royal HaskoningDHV (2018) HNP (2018a) Regnault (1994) Bennett (1995) MarLIN (2019)
Spider crab	This species is thought to move offshore during the autumn and inshore during the spring.	Adults occur in sublittoral to depths of 90 m, on rocky bottoms with algae. Juveniles prefer shallows on mixed soft/hard bottoms	Only use slow, small-scale, non-directional movements	Feed upon algae and molluscs during the winter and echinoderms during the summer; general omnivorous diet	Royal HaskoningDHV (2018) Bernardez *et al.* (2000) SealifeBase (2019)
Velvet swimming crab	Mating occurs after the moult. Females bear eggs mostly in spring, eggs hatch in late spring	Shallow and intertidal to 80 m	Females migrate to soft substrates for egg laying	Opportunistic feeder, mostly on molluscs and crustaceans but also detritus and algae	HNP (2018a) SeaLifeBase (2019)

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
European lobster	Mating takes place in the summer and is annual or bi-annual. Eggs carried for 10-11 months.	Rocky and stony substrata, usually not deeper than 50 m	Do not undertake migrations; will only move a few miles along the shore	Preys on crabs, molluscs, sea urchins, polychaete worms and starfish	Royal HaskoningDHV (2018)
Blue mussel	Peaks in spawning in spring and summer	Occurs from the high intertidal to the shallow subtidal. Uses fibrous byssus threads to attach to suitable substrata	N/A	Filter feeders and collect algae, detritus and organic material	Royal HaskoningDHV (2018) Cefas (2014) MarLIN (2019)
Native oyster	Spawning is frequent, most often between June-September	Estuarine and shallow coastal water habitats on mud, rocks, muddy sand, muddy gravel with shells, and hard silt.	N/A. Dispersal of young estimated to be more than 10 km	Filter feeders of phytoplankton	Royal HaskoningDHV (2018) MarLIN (2019)
King scallop	Scallops spawn in spring or summer and probably require dense concentrations to achieve the successful production of larvae.	Coarse gravel with some erect epifauna and shell is known to be suitable for successful settlement and recruitment of larvae to the stock.	N/A	Filter feeder	Royal HaskoningDHV (2018) HNP (2018a)
Queen scallop	Scallops spawn in spring or summer and probably require dense concentrations to achieve the successful production of larvae.	Coarse gravel with some erect epifauna and shell is known to be suitable for successful settlement and recruitment of larvae to the stock.	N/A	Filter feeder	Royal HaskoningDHV (2018) HNP (2018a)
Common whelk	Whelk have a low fecundity and entirely benthic reproductive strategy. Whelk spawn between November and January, laying distinctive egg masses which are then	Muddy sand, gravel and rock.	Common whelk has low growth rates and restricted adult movements.	Carnivorous predator and active scavenger.	Royal HaskoningDHV (2018) HNP (2018a) MarLIN (2019)

Species	Seasonality	Habitat Association	Migration	Predator-Prey relationship	Sources
	attached to suitable substrate.				
Common cockle	Main reproductive season is May-June	Burrows in sand, mud, and gravel substrate in intertidal zone	N/A	Filter feeder	Cefas (2014) MarLIN (2019)
Common prawn	Mating directly after first moult; females carry eggs for 9-11 months	Rocky and muddy bottoms in the shallows (up to 40 m)	Occur in shallows (feeding and nursery habitat) during summer months and in deeper water during winter. Also tidal and diurnal migrations	Omnivorous, feeding on seaweed and small crustaceans	SeaLifeBase (2019)
Common/green shore crab	Berried females found January-May. Eggs hatch in spring/summer	From high water to 60 m depth, though most common in shallows. Found on all types of shore	Generally no migration, though females in estuary move to mouth of estuary to lay eggs	Omnivore, both animal and plant matter from a variety of species	MarLIN (2019)

10.5.8. Migratory Fish

101. There are several species of fish which spend part of their life cycle in the marine environment and the other in the freshwater environment, i.e. diadromous species. Whilst they are in the marine environment they may have the potential to overlap with the Project. It is therefore important to understand their migration patterns to determine whether they require assessment in this chapter. The migratory patterns of diadromous species are outlined in **Table 10-16**.

Table 10-16 Migratory Periods of Key Diadromous Species

Species	Time spent in freshwater before downstream migration	Timing of downstream migration	Time spent at sea before first return	Timing of upstream migration
Atlantic salmon	2-3 years	April- May (Smolt)	1, 2 or 3 years	All year round with peak in late summer early autumn (Adults)
Sea trout	2-3 years	Spring/early summer	2 or more in coastal areas	April- June
European eel	Males 7-20 years Females 9-50 years	Late spring (as silver eels)	Many do not return to fresh water	January to June (as juvenile glass eels)
Sea lamprey	3-4 years	July to September to open sea	18-24 months	April-May spawning in May/June
River lamprey	5 years or more. Remain in burrows in river silt beds until adults	July to September to feed in estuaries	2 years spent in estuaries.	Winter and spring when temps are <10oC. Migrate at night
Allis and Twaite Shad	Short period few months (Juveniles)	April/May (Juveniles)	3-4 years Estuarine areas	April to May spawning in freshwater

102. As a precautionary measure all species considered to have a migratory pathway overlapping the site in the HRA are scoped in for assessment here. This includes Atlantic salmon, both species of lamprey and both species of shad. Though it should be noted that there are no natal rivers for any of these species on the coastline adjacent to the MDZ.

103. The European eel undertakes extensive migration from rivers around the UK to their spawning grounds in the Sargasso Sea, North America. Eels travelling through the Irish Sea therefore migrate in a southerly direction, exiting through the southwest approaches. There are known stocks of European eel to the north of the site (Bark et al., 2007), therefore it can be considered that the species may overlap with the site and as such should be assessed.

104. Sea trout are present in the rivers of Anglesey, although it should be noted that no such rivers have mouths adjacent to the MDZ. When they move into the marine environment sea trout remain in coastal waters, as they have very limited migrations in terms of distance, although there is limited information on the range. Due to the lack of knowledge on at-sea migration and the presence of sea trout rivers nearby, this species has been screened in as a precautionary measure.

10.5.8.1. Commercial Importance

105. Most of the species listed in Table 10-16 are not commercially landed whilst at-sea, hence their absence from TACs and catch data from ICES Rectangle 35E5. The exception is European eel, for which ICES state that all anthropogenic impact (including recreational and commercial fishing) should be "reduced to – or kept as close to – zero as possible."

106. Across England and Wales in 2015 catches of eel (across all life stages) weighed a total of 25,000 kg (Environment Agency, 2017), indicating species value despite the near-zero TAC. By contrast lampreys caught in England and Wales in 2015 weighed 285 kg (Environment Agency, 2017), indicating limited commercial importance.

107. Atlantic salmon and sea trout are of importance to the recreational fishing industry in Wales. These species are typically caught by rod (of which, most are released) and by net. In Wales approximately 3,000 salmon and 15,000 sea trout were caught in 2015 (Environment Agency, 2017).

108. Shad are considered rare and as such are not meant to be fished in Wales.

10.5.8.2. Spawning/Nursery grounds

109. There is no predicted overlap between the study area and any spawning grounds of diadromous species. Almost all of the diadromous species return to freshwater to spawn; the exception is the European eel, though these spawn in the Sargasso Sea, North America.

110. Nursery grounds for the freshwater spawning fish can typically include coastal areas at the base of the rivers they have spawned in. There are no estuaries adjacent to the project, therefore it is not considered that it will overlap with any nursery areas.

10.5.8.3. Nature Conservation Status

111. The nature conservation status of migratory fish species is detailed in **Table 10-17**.

112. Of the migratory fish species listed in **Table 10-16** there are five that are listed under Annex II of the Habitats Directive. These species, listed in **Section 10.5.3.3**, are the sea lamprey, river lamprey, allis shad, twaite shad, and Atlantic salmon. These are all the species listed on Annex II that are known to enter the marine environment.

113. There are 20 SACs in the vicinity of the study area that are designated for Annex II migratory fish species. The location of these SACs are shown in **Figure 10-4** (**Volume II**). The nearest SAC, Afon Gwyrfai a Llyn Cwellyn, is approximately 30 km distance from the study area.

114. It is possible that individuals from populations designated under these sites may occur in the study area, due to their migratory behaviour. All five Annex II migratory fish species have populations in these nearby SACs.

115. The European eel is also an MCZ (highly mobile) species FOCI (JNCC, 2016), though no MCZs are designated for this species in the vicinity of the study area.

Table 10-17 Nature Conservation Status of Migratory Fish Species Found Within the Study Area

Common Name	Nature Conservation Status							
	IUCN Red List	OSPAR Annex V (list of species threatened and / or in decline)	NERC Act 2006 Section 41 (England)	Environment Act Section 7 (replaced NERC Act Section 42 (Wales))	UK Biodiversity Action Plan (BAP)	UK Wildlife and Countryside Act 1981 Schedule 5	Habitats Directive	Common Fisheries Policy zero TAC species
Atlantic salmon	Global: Least Concern; Europe: Vulnerable (A2ace)	Yes	Yes	Yes	No	No	Yes	Not assessed
Sea trout	Least Concern	No	Yes	Yes	No	No	No	Not assessed
European eel	Critically Endangered (A2bd+4bd)	Yes	Yes	Yes	No	No	No	Yes
Sea lamprey	Least Concern	Yes	No	Yes	No	No	Yes	Not assessed
River lamprey	Least Concern	No	No	Yes	No	No	Yes	Not assessed
Allis shad	Least Concern	Yes	Yes	Yes	No	Yes	Yes	Not assessed
Twaite shad	Least Concern	No	Yes	Yes	No	Yes	Yes	Not assessed

10.6. IMPACT ASSESSMENT

10.6.1. Overview of Potential Impacts

116. **Table 10-18** provides a brief list of the potential impacts on fish and shellfish that may arise during activities undertaken during each phase of the Project.

Table 10-18 Potential Impacts of the Project Phases on Fish and Shellfish

Phase	Potential Impact
Construction	Impact 1: Underwater Noise Impact 2: Physical disturbance of habitats and temporary habitat loss Impact 3: Increased suspended sediment concentration and sediment deposition
Operation and Maintenance	Impact 1: Underwater Noise (and via repowering) Impact 2: Long-term habitat loss via placement of project infrastructure (project footprint) (and via repowering) Impact 3: Physical disturbance of habitats and temporary habitat loss (repowering only) Impact 4: Increased suspended sediment concentration and sediment deposition (repowering only) Impact 5: Barrier Effects Impact 6: Collision Risk Impact 7: Electromagnetic Fields
Decommissioning	Impact 1: Underwater Noise Impact 2: Physical disturbance of habitats and temporary habitat loss Impact 3: Increased suspended sediment concentration and sediment deposition

117. It should be noted that the impact of Invasive Non-Native Species (INNS) is addressed in **Chapter 9, Benthic and Intertidal Ecology**.

10.6.2. Embedded Mitigation

118. The following assessment provides a summary of all impacts identified during scoping study and those which have been noted as the EIA has progressed. These impacts are not relevant to all stages of the project, and thus impacts have been assessed within the stage of the project at which they will occur (construction, operation and decommissioning). Further, these impacts are comprised of both direct and indirect impacts.

119. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process (see **Chapter 4, Project Description** for further details). A range of different information sources has been considered as part of embedding mitigation into the design of the project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

10.6.3. Worst Case Parameters

10.6.3.1. Temporary Habitat Disturbance

120. During all project phases, temporary habitat disturbance will occur to seabed habitats via device, hub and cable installation and also anchor deployments for installation barges. Based on information provided in **Chapter 4, Project Description** the following values listed in **Table 10-19** have been calculated to define the worst-case parameters for temporary habitat disturbance. These are defined in terms of project phase, as different amounts of temporary seabed disturbance are predicted to arise in each phase.

121. For the purpose of defining impact assessment parameters for the repowering phase, an assumption has been made that 50 % of the tenants will undertake repowering, i.e. for 50 % of the tenants, their infrastructure will be removed and replaced (potentially with different infrastructure by a different tenant). For the other 50 % of tenants, their infrastructure will remain over the lifetime of the project.

122. In terms of impact assessment parameters, the repowering process has, therefore, been defined as per below:

- Initial temporary seabed disturbance via deployment of barge anchors to remove foundations, TEC's, hubs, inter-array cables and monitoring equipment for 50 % of the Tenants (berths); and
- Further temporary seabed disturbance via re-installation (repowering) of foundations, TEC's, hubs, inter-array cables and monitoring equipment for the same 50 % of Tenants (berths).

123. The operational phase values also include the temporary seabed disturbance that would arise from up to ten cable repair events.

Table 10-19 Summary of Worse-Case Scenario Temporary Habitat Loss during Construction, Operation (repowering) and Decommissioning Phases

Project Component	Worse Case (240 MW)	Unit	Notes
Construction Phase:			
Post-lay burial of cable	27,259	m^2	Area of sandwave field where post-lay burial via Mass-Flow Excavator (MFE) may be required
Deployment of anchor blocks by barges during cable installation	100,240	m^2	Up to 8 x 25 m^2 (5x5) m anchor blocks for a single barge = a total footprint per anchor deployment of 200 m^2 (8 x 25 m^2) Assumed that these types of anchor barges generally deploy a spread every 500 m. So, for every 500 m of cable installation a footprint of 200 m^2 of temporary seabed disturbance occurs (via the anchor blocks) Combining all potential export, array and cable tails the total length of cables (full 240 MW) is 250.6 km

Project Component	Worse Case (240 MW)	Unit	Notes
			Assumes the footprint of 200 m^2 every 500 m (0.5 km), or 400 m^2 every 1 km, and assumes all cables are installed using anchor barges Temporary disturbance impact of (400 m^2 x 250.6) = 100,240 m^2 (0.10 km^2) "
Deployment of anchor blocks by barges during TEC device installation	248,000	m^2	Max. no of devices set at 620 x small (0.3 kW devices) Assumed that deployment of each device requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2) Therefore, total temporary seabed disturbance = 620 x 400 m^2 = 248,000 m^2
Deployment of anchor blocks by barges during hub installation	48,000	m^2	Max. no of seabed mounted hubs set at n = 120 Assumed that deployment of each hub requires 2 x anchor deployments from barge (2 x 200 m^2 = 400 m^2) Therefore, total temp. seabed disturbance = 120 x 400 m^2 = 48,000 m^2
Construction Phase TOTAL		**423,499 m^2 (0.42 km^2)**	
Operational Phase:			
(Repowering) 50 % of tenants infrastructure (Foundations; TEC's; hubs' array cables; monitoring equipment) removed and replaced with new (different) tenant infrastructure	377,400	m^2	Initial removal of tenant infrastructure from 50 % of berths • 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 • 50 % of anchor block value of tidal device installation = 124,000 m^2 • 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2 Subsequent re-installation (re-powering) of tenant infrastructure from 50 % of berths • 50 % of anchor block value (above) for inter-array cables only (203.5/2 * 0.4) = 40,700 m^2 • 50 % of anchor block value of tidal device installation = 124,000 m^2 • 50 % of anchor block value for hub installation = 24,000 m^2 Sub-Total = 188,700 m^2
Cable repairs	3,000	m^2	Up to 10 major cable repairs (5 days each) may be required throughout the project life. It is assumed that up to 750 m of cable will be subject to repair works per event (7,500 m in total). Using same value of 400 m^2 temp seabed disturbance per 1 km of cable works (400 x 7.5) = 3,000 m^2
Operational Phase TOTAL		**380,400 m^2 (0.38 km^2)**	

Project Component	Worse Case (240 MW)	Unit	Notes
Decommissioning Phase:			
Decommissioning Phase		**TOTAL 423,499 m^2 (0.42 km^2) –** same worst-case as per construction phase due to same activities needed to remove infrastructure	

10.6.3.2. Permanent Habitat Loss via Project Infrastructure

124. The installation of project infrastructure, including anchor systems for TEC devices, seabed mounted devices, hubs and cables/cable protection, will all result in permanent habitat loss. Based on information provided in **Chapter 4, Project Description** the following values listed in **Table 10-20** have been calculated to define the worst-case parameters for permanent habitat loss via project infrastructure. The majority of these effects will only occur in the operational phase. The exception is the value of 7,400 m^2 related to the trench for up to 9 cables at landfall. Trenching of cables will only be undertaken if horizontal directional drilling (HDD) works (preferred method) are not possible/viable. Without detailed geotechnical analysis it is not currently possible to state if trenching, and subsequent backfill of the trench(es) would be possible. If it was, this would represent a temporary disturbance on intertidal habitats. However, to ensure a precautionary approach is built into the assessment, it has been concluded that trenching/surface-laying of the landfall cables would lead to permanent habitat loss, thus this value is included below.

125. As detailed above, the permanent habitat loss values also account for additional permanent habitat loss due to placement of re-installed (repowered) foundations/TECs in different areas to where originally installed.

Table 10-20 Summary of Worse-Case Scenario: Permanent Habitat Loss via Project Infrastructure (including repowering)

Project Component	Worse Case (240 MW)	Unit	Notes
Main operational phase			
Gravity Base Structures (GBS)	74,790	m^2	Max value across entire project. Based on anchor mooring systems for floating devices. Includes hubs.
Swept Area of Catenary Cables	2,055,000	m^2	Based on: 30 devices having swept area of 9,500 m^2 (large floating devices (Orbital, Magallanes) 140 devices having swept area of 7,500 m^2 floating devices (Tocardo UFS, Aquantis) & hubs 240 devices having swept area of 3,000 m^2 small floating devices (Instream, SME PLATO)
Export Cable Footprint (cables; protection systems; rock bags)	11,745	m^2	Up to 40.5 km of export cables (with split-pipe protection/shells and rock bags)

Project Component	Worse Case (240 MW)	Unit	Notes
Array Cable Footprint (cables; protection system; rock bagss)	30,040	m^2	Up to 204.5 km of array cables (with split-pipe protection/shells and rock bags)
Cable tails	120	m^2	Based on 9 x tails of 620 m length
Trench for 9 x landfall cables	7,400	m^2	740 m long trench x 10 m width in intertidal region
Footprint of Navigation Marker Buoys	540	m^2	3 m diameter square gravity anchor (9 m^2) per anchor x 60 anchors/buoys
Footprint of ADCP moorings	280	m^2	7 m^2 per ADCP mooring x 40 units
Footprint of seabed mounted environmental monitoring units	112	m^2	14 m^2 per env monitoring unit x 8 units
Footprint of mooring for floating environmental monitoring units	45	m^2	9 m^2 per mooring x 5 units
Permanent habitat loss (initial operational phase: 2,180,072 m^2 (2.18 km^2)			
Repowering Phase			
New tenant infrastructure in 50 % of berths	52,504	m^2	See **Chapter 4, Project Description** for more details
Permanent habitat loss (repowering of 50 % of berths): 52,504 m^2			
Permanent Habitat Loss: Total of 2,232,576 m^2 (2.23 km^2)			

10.6.3.3. Underwater Noise

126. The installation of project infrastructure, including drilling for pin piles and cable installation, will result in the production of underwater noise. Therefore, as per **Chapter 12, Marine Mammals**, the assessment has been based on underwater noise modelling that has been conducted for the nearby Wylfa Newydd Development Area, the Perpetuus Tidal Energy Centre (PTEC) off the coast of the Isle of Wight and MeyGen in the Inner Sound of the Pentland Firth.

127. For each of the three projects modelling was undertaken in order to make an assessment of the source levels of underwater noise from several potential noise sources expected to occur during construction. All three projects made an assessment of the levels of underwater noise emitted from drilling and vessels. The results of the modelling studies have been provided in **Table 10-21**.

Table 10-21 Summary of Worse-Case Scenario: Subsea Noise Effects

Project Component	Worse Case (240 MW)	Notes
Noise from drilling of pin piles	Predicted source level was 179.8 dB re 1 μPa@1 m (RMS)	From PTEC (2014). Note that these results reflect the worst case scenario of drilling (4 m pin piles, 333 kW drill).
	Predicted unweighted source level of 185.3 dB re 1 μPa (RMS) @ 1 m	From Wylfa Newydd Development Area (HNP, 2018b).
	Drilling noise measurements of up to 178 dB re 1 μPa @ 1 m	From MeyGen (Kongsberg, 2012).
Vessel noise	172 dB re 1 μPa @ 1 m	From MeyGen (Kongsberg, 2012). Note that this value comes from assessment of noise from a tugboat, the noisiest type of vessel likely to be used during operations at MeyGen.
	170 – 180 dB re 1 μPa @ 1 m	From PTEC (2014).
	168 dB re 1µPa (RMS) @ 1 m for large vessels; 161 dB re 1µPa (RMS) @ 1 m for medium vessels	From Wylfa Newydd Development Area (HNP, 2018b).

128. PTEC (2014) give a high-level summary of the expected species-specific impact ranges from these other sources of underwater noise; these are provided in the following section.

10.6.3.4. Construction Programme

129. The construction of offshore works (for installation of tidal devices and associated cabling and infrastructure) would be phased over a period of several years, taking up to 15 days per device or hub and up to 1.5 days for each inter-array cable, up to 20 days for each offshore cable, and up to 12 days for each phase of cable protection. Up to eight separate cable laying and protection campaigns are possible. The HDD at the landfall would be completed over a four to six month period with two months for offshore cable tail installation.

10.6.4. Potential Impacts during Construction

10.6.4.1. Construction Impact 1: Underwater Noise Effects

130. Underwater noise may arise from the installation of project infrastructure, including TEC devices, cables and electrical hubs. Of the proposed foundation systems, the worst-case scenario for the production of underwater noise is predicted to be from pin pile foundations. These may need to be installed using drilling due to the hard substrate in the study area. The maximum amount of drilling that could arise would be 1,280 drill holes, which at three days each, would result in a total of 3,840 days of drilling on site to install the full 240 MW capacity.

131. In order to assess the potential impacts from underwater noise emitted during drilling the results from the three similar underwater noise modelling studies of percussive drilling have been utilised here (see **Table 10-21**).

132. The sensitivity of fish species to noise is poorly understood though it is thought to vary between species, depending on several factors including the auditory ‘threshold’, presence of and physical coupling of any swim bladder to ear structures, resonance frequency of the otolith system, and behavioural traits (Kongsberg, 2012; PTEC, 2014). Examples of predicted hearing sensitivity of different fish species are given in **Table 10-22**. It should be noted that shellfish are considered insensitive to noise due to the absence of a swim bladder (PTEC, 2014) and so have not been included in this assessment.

Table 10-22 Hearing Specialisation of Various Species of Fish Present in the Region (adapted from Kongsberg, 2012; PTEC, 2014)

Species	Family	Swimbladder connection	Sensitivity
Atlantic salmon/sea trout	Salmonidae	None	Medium
European eel	Anguillidae	None	Medium
Cod	Gadidae	None	Medium
Plaice	Pleuronectidae	No swim bladder	Low
Elasmobranchii		No swim bladder	Low
Mackerel	Scombridae	No swim bladder	Medium
Herring	Clupeidae	None	Medium

133. Underwater noise can cause a range of effects in fish, depending on the noise level produced. The sound levels at which different effects may be seen are as follows (from Parvin et al., 2007):

- Physical injury to mortality – 220-240 dB re 1uPa
- Strong behavioural reaction - 90 dB re 1uPa
- Mild behavioural reaction – 75 dB re 1uPa

134. All three modelling studies demonstrated that the noise produced by percussive drilling did not exceed the sound levels for physical injury to mortality. However, levels associated with behavioural changes can be emitted. Behavioural changes in fish can result in changes to migration, feeding, spawning etc. therefore they are important to assess.

135. The level of behavioural impact will depend on the apparent loudness of the noise source perceived by the target species. This can be calculated using the dB_{ht} technique, where the frequency spectrum of the source noise is compared with the hearing threshold of the target species. The dB_{ht} (species) metric and associated effect of exposure have been calculated by Nedwell et al. (2007) and are provided in **Table 10-23**. This metric was used in the modelling for PTEC (2014) and MeyGen (Kongsberg, 2012).

Table 10-23 Assessment Criteria used for the Potential Impact on Marine Species (after Nedwell et al., 2007)

Sound level dB_{ht} (Species)	Effect of exposure
Above 130	Possibility of traumatic hearing damage from a single event
90	Strong behavioural reaction

Sound level dB_{ht} (Species)	Effect of exposure
75	Some avoidance reaction by the majority of individuals, but habituation or context may limit effect

136. PTEC (2014) assessed that no physical or injury effects were predicted from noise levels emitted during drilling as determined in the noise modelling study. Behavioural reactions were predicted to different extents and at different ranges for the modelled species, as outlined in **Table 10-24**. Cod were demonstrated to be the most sensitive species to sound, showing a behavioural reaction at distances up to 50 m and a "startle" reaction at distances up to 8 m from the source (PTEC, 2014). The results for this species are considered the worst-case scenario and any other species are not considered likely to have a greater impact from noise.

Table 10-24 Summary of the Modelled Ranges for 90 and 75 dB_{ht} (Species) Levels for Worst-Case Scenario Percussive Drilling (taken from PTEC, 2014)

Species	90 dB_{ht} (Species)			75 dB_{ht} (Species)		
	Max Range (m)	Min Range (m)	Mean Range (m)	Max Range (m)	Min Range (m)	Mean Range (m)
Bass	<1	<1	<1	4	3	4
Cod	8	7	8	50	49	50
Dab	3	2	3	16	15	16
Salmon	<1	<1	<1	5	4	5
Elasmobranch	<1	<1	<1	<1	<1	<1

137. Kongsberg (2012) also assessed the distance from drilling activities at which the two metrics for behavioural reactions would occur (90 dB_{ht} and 75 dB_{ht}). They determined that both metrics (i.e. types of behavioural impact) would only occur within 1 m of the sound source, for both hearing specialists and generalists, under the most precautionary conditions. As a result, it was concluded that behavioural reactions are unlikely to be observed in fish species.

138. The underwater noise modelling undertaken for Wylfa Newydd were calculated based on Popper *et al.* (2014), and specifically assessed the distance at which the sound level would cause a recoverable injury (after 48 hours of exposure to continuous percussive drilling noise, using 170 dB re 1 µPa (SPL_{RMS})), and the distance at which the sound level would cause a temporary threshold shift (TTS) (after 12 hours of exposure, using 158 dB re 1 µPa (SPL_{RMS})), for fish with swim bladders involved in hearing i.e. hearing specialists. The maximum distance at which a recoverable injury would be caused was 7 m. The maximum distance at which TTS would occur was 67 m.

139. The impact ranges of vessel noise were assessed for the three projects, based on the source level metrics provided in **Table 10-24**. The modelling studies for MeyGen (Kongsberg, 2012) and PTEC (2014) utilised the dB_{ht} metric to assess the impact ranges from vessel noise on fish. Kongsberg (2012) predicted that the lowest level of noise that could cause a behavioural impact would occur up to 1 m from the vessel, under the most precautionary conditions, and for hearing specialists as well as generalists. PTEC (2014) indicate that the most sensitive species (cod) would receive sufficient sound levels to exhibit a behavioural impact at a maximum distance of 8 m from a large vessel (i.e. the worst-case scenario).

140. For the Wylfa Newydd project, HNP (2018b) assessed the vessel noise as a continuous noise, using the same metrics that were used for modelling drilling sound. The maximum distance at which a recoverable injury would be caused was <1 m for both large and medium vessels. The maximum distance at which TTS would occur was 4 m for large vessels, and <1 m for medium-sized vessels.

141. PTEC (2014) also assessed the behavioural impact ranges from other construction activities, specifically trenching and cable protection. For the most sensitive species (cod), the impact range for trenching was 1 m (using the 90 dB_{ht} metric) and 16 m (using the 75 dB_{ht} metric). For cable protection, the impact range was 2 m (using the 90 dB_{ht} metric) and 25 m (using the 75 dB_{ht} metric).

142. From the evidence presented it can be determined that the highest noise levels during installation will be emitted by drilling. The maximum impact range for fish during this activity is predicted to be 67 m. This contour is considered to be low; as a result, the maximum concluded sensitivity for fish receptor species is medium.

143. As part of the construction phase of operations it is anticipated that the installation of each hub may take up to 15 days. Under full site deployment circumstances, this could result in a total of 1,800 days (just under 5 years) of installation. It should be noted that these days are likely to occur concurrently for different devices, although the extent to which construction will overlap is not known. Due to the short-term scale of construction operations and taking into consideration the small extent of the site in the context of available habitat in the surrounding area, it is considered that the magnitude for effect is low.

144. As a result of the low magnitude of the effect in coupled with the medium sensitivity of the receptor there is a **minor adverse** impact on the receptors during construction.

10.6.4.1.1. Mitigation

145. No mitigation measures are considered to be required.

10.6.4.1.2. Residual Impact

146. The residual impact is **minor adverse**.

10.6.4.2. Construction Impact 2: Temporary Habitat Disturbance

147. Temporary seabed habitat disturbance will occur during the construction phase of the project via a range of effects including deployment of anchor blocks for installation barges and cable installation works.

148. The total area of seabed predicted to be subject to temporary disturbance over the duration of the construction phase is detailed in **Table 10-19.** This value of 423,499 m^2 (0.42 km^2) will not arise at one time as construction will be phased over several years. However, for the purpose of this assessment, this total amount of temporary habitat disturbance has been assessed.

149. Based on the values presented in **Table 10-19**, the total amount of temporary disturbance of habitat due to the deployment of anchor blocks during the construction phase will be 396,240 m^2 (0.39 km^2). It should be noted that this is highly precautionary as it is unlikely that a moored barge will be used to install all cables (a Dynamically Positioned (DP) vessel will likely be used for some cables which produces no seabed disturbance). This amount of temporary seabed disturbance equates to disturbance of less than 1% of the wider habitat within the MDZ. This disturbance will also be short-term, and as such is also classified as having a **low** magnitude.

150. The fish and shellfish species found in the study area are typical of this region and are widely distributed throughout the surrounding area. The study area does not represent unique habitat for any given species. The study area does lie within an area of low intensity spawning ground for cod, whiting, sandeel, mackerel, plaice and (dover) sole; a low intensity nursery ground for whiting, sandeel and plaice; and high intensity nursery ground for sole (Coull et al., 1998; Ellis et al., 2012; Pawson and Robson, 1996). Coull et al. (1998) also determined that the area was a spawning ground for sprat, in agreement with Aires et al. (2014) who indicated a high number of 0-year sprat in the area. The low intensity grounds listed for the species are typically widespread (Coull et al., 1998; Ellis et al., 2012; Pawson and Robson, 1996) and so not restricted to the study area. Similarly, the high intensity nursery ground for sole extends into the eastern Irish Sea, and it should also be noted that it is a “nominal” nursery ground due to the presence of juveniles only (Ellis et al., 2012). Indeed, the data in Coull et al. (1998) and Ellis et al. (2012) are high-level and broad scale and therefore is intended only to be used indicatively.

151. The worst-case scenario, therefore, is that the area is used as a low intensity spawning ground and a high intensity nursery ground for certain common, commercially important species. Due to the presence of this key life stage the sensitivity of fish receptors is considered medium, taking into account the fact that the study area represents a very small proportion of the total spawning and nursery grounds available to the species in the wider region.

152. Shellfish species typically occupy the seabed and as such are considered sensitive to habitat loss. Three representative species have been chosen for an assessment of sensitivity: blue/common mussel *Mytilus edulis* as a representative sessile species; and European spiny lobster[1] *Palinurus elephas* (as a proxy for mobile species). Blue mussel and European spiny lobster have undergone sensitivity assessments that are presented on MarLIN (2019).

153. Blue mussel is considered as having a moderate sensitivity to substratum loss and a low sensitivity to abrasion and physical disturbance. European spiny lobster is assessed as having a medium sensitivity to the abrasion/disturbance of the surface of the substratum or seabed. As a result, it is assessed that the worst-case scenario for sensitivity of shellfish receptor species is medium.

[1] European spiny lobster, though not found in the study area, is a similar species to the European lobster found in the study area, therefore it has been used as a proxy for effects on this species as it has undergone a sensitivity assessment on MarLIN.

154. The study area is subject to high tidal energy therefore the site is mainly exposed bedrock and boulders, though in the north there are sand and gravel habitats, in addition to the sandbank. The habitats suitable for spawning and nursery are therefore present across large portions of the study area, greater than the potential lost habitat. They are also present across the wider region, as revealed by the biotope mapping in **Chapter 9, Benthic and Intertidal Ecology**.

155. As a result of the low magnitude of the effect in coupled with the medium sensitivity of the receptor there is a **minor adverse** impact on the receptors during construction.

10.6.4.2.1. Mitigation

156. No mitigation measures are considered to be required.

10.6.4.2.2. Residual Impact

157. The residual impact is **minor adverse**.

10.6.4.3. Construction Impact 3: Increased Suspended Sediment Concentrations and Sediment Deposition

158. Increased suspended sediment concentrations and sediment deposition can arise during the construction phase due to installation of infrastructure on the seabed (foundations, hubs and cables). As the study area is highly tidal, with high nearbed transport, there is minimal fine sediment present.

159. Furthermore, any sediment that may be deposited as a result of construction activities will be immediately minnowed and un-detectable beyond a small spatial (100 m) and temporal (few tidal cycles i.e. days) scale. Though no specific modelling has been conducted, it is expected that there may be localised increased in sediment levels above 10 mg/l but these will rapidly disperse.

160. Specifically, during drilling of foundations it is expected that suspended sediment will not be detectable above background levels beyond 100 m. There are no sediment plumes to be expected to arise during construction that will significantly increase the suspended sediment concentration (SSC) or result in smothering from deposition. Deposition is considered to be effectively immeasurable at the benthic level.

161. For cable installation works, there is also potential for some sediments to be disturbed, creating a plume, particularly in the nearshore part of the cable (within ‘Abraham’s Bosom’). Any plume created will be short-term and will be dispersed by tidal current action until coarser sediments settle once again on the sea bed.

162. The principal causes of sediment disturbance during offshore cable installation would be:

- Free-laying of up to 35 km of offshore cable on the sea bed;
- Placement of cable protection (rock bags of concrete mattresses) at specific locations along the cable length; and

- Post-installation jetting to bury offshore cable across the sand ridge feature in the northern half of the cable corridor.

163. The free-laying of cables and the placement of cable protection would not cause plumes along the offshore sections of the cable corridor because the sea bed is characterised by bedrock or, where sparse sediment cover does exist, by sediments with a particle size that cannot be suspended in the water column. In the nearshore, the bedrock is overlain by sand which has the potential to be disturbed by the free-laying of cables and the placement of cable protection. However, any plume arising from these activities would only arise from the force of the cable or protection measures on the sea bed. At the landfall, the worst case scenario would be open trenching rather than the preferred option of HDD. Under open trenching, up to 7,440 m^3 of sand would be excavated and the majority replaced to backfill the trench, with only a small net loss to the inshore system. Due to these factors, the likely increase in suspended sediment concentration in areas with sand cover nearer to shore (including at the landfall) will remain within the bounds of natural behaviour that are governed by storm waves and surge effects. Furthermore, these effects will be one-off and temporary in duration and are unlikely to be measurable.

164. The principal effect would arise from the post-installation jetting to bury the offshore cable across the sand ridge feature in the northern half of the cable corridor. Under this activity, it is likely that the maximum envisaged effect associated with sediment plumes arising from the jetting will cause only modest (but measurable) increases in suspended sediment concentration locally (typically a few tens of mg/l above background levels). This increase would reduce rapidly with distance from the point of disturbance to a few mg/l over a small geographical area (within a few hundred metres, along the axis of tidal currents).

165. Furthermore, these effects will be one-off and temporary in duration, with a return to the very low background concentrations occurring rapidly upon cessation of installation.

166. With respect to sediment deposition, from experience of similar schemes, it is envisaged that in the immediate vicinity (up to 10 m from point of jetting) of the post-lay jetting through the sand wave area, deposition depths of no more than 0.1 m will be observed. These are highly likely to become quickly re-entrained by currents during the peak velocities of the following tide and transported further away in small concentrations.

167. Further away from the immediate vicinity of the post-lay jetting, the deposition of sediments would extend over a similar zone of influence to that of the sediment plume (i.e. within a few hundred metres of each release point, following the axis of the tidal current flow). Within a short distance from the release points the thickness of deposits will be extremely small, typically millimetres. In this highly dynamic tidal area, this is effectively an immeasurable change.

168. Overall, the magnitude of effect of increased suspended sediment and deposition is judged to be negligible for all areas apart from the sandwave area, where a low magnitude effect may arise (near-field).

169. The species considered most sensitive to increased sediment and deposition are the shellfish species. The blue (or common) mussel and European spiny lobster, have been used for assessing sensitivity to sediment changes, through the information presented on MarLIN (2019).

170. European spiny lobster is assessed as having a medium sensitivity to changes in suspended solids (water clarity) and is not sensitive to 'light' smothering and siltation rate changes. Blue/common mussel have a low sensitivity to smothering and are considered not sensitive to an increase in suspended sediments. Therefore, the worst-case scenario is a medium sensitivity of the receptor (also taking into account the receptor value).

171. As a result of the low/negligible magnitude of the effect in coupled with the medium sensitivity of the receptor there is a **minor adverse** impact on the receptors during construction.

172. It should also be noted that turbidity can positively impact the larvae of fish and shellfish species. Increased turbidity can create a "shading effect" which can lead to a reduction in predation rate on fish larvae, thereby increasing survival (Fiksen et al., 2002). The extent of this effect will likely vary depending on the trophic level of the larvae. Due to this species-specific variation this impact has not been directly considered as part of the impact assessment. However, it can be thought that the magnitude of adverse effect may be somewhat offset by this potentially positive effect.

10.6.4.3.1. Mitigation

173. No mitigation measures are considered to be required.

10.6.4.3.2. Residual Impact

174. The residual impact is **minor adverse**.

10.6.5. Potential Impacts during Operational Phase

10.6.5.1. Operational Impact 1: Underwater Noise Effects via (a) device operational noise and (b) repowering works

175. There is very little information on the operational noise produced by tidal devices. However, the information available has informed a number of preceding EIA studies, including the recently consented PTEC project. The results from the noise modelling conducted for the PTEC project (2014) and MeyGen (Kongsberg, 2012) have been applied to this project. Information from the Technical Note produced by Subacoustech (2019) for this project are also used.

176. Subacoustech (2019) reviewed the noise outputs of a suite of tidal devices. It was reported that predicted source noise levels ranged from 145 to 175 dB re 1 uPa @ 1 m. The corresponding frequency range was rarely reported. One turbine design with the most information available, OpenHydro, has a predicted source noise level of 152 dB SPL_{RMS}, with the majority of the energy centred on the 125 Hz 1/3 octave frequency band. This low frequency noise is within the typical frequency range of the predominant component of ambient noise (Subacoustech, 2019) as well as fish hearing ability (e.g. salmon; Harding *et al.,* 2016). The noise emitted from OpenHydro was reported to reach background noise levels within 1-1.5 km from the source.

177. For the PTEC project (2014), modelling was conducted of operational noise that would arise using 24 m rotor (worst-case scenario for this project). Note that this is smaller than the maximum rotor size potentially proposed for the Project, 27 m, however, the scale of potential effect on fish species associated with the noise of tidal turbines from PTEC and MeyGen shows

range to be limited to the low 10s of metres at greatest, and this is expected for other tidal turbines of a similar scale.

178. The worst-case scenario modelling for the 24 m rotor at threshold levels (90 dB_{ht} and 75 dB_{ht} (Species) (Nedwell et al., 2007)) for impact on fish species are listed in **Table 10-25**. The largest range at which a behavioural reaction can be expected (i.e. levels of 75 dB_{ht} are reached) is 36 m, specifically for cod species. The largest range at which a startle response can be expected (i.e. levels of 90 dB_{ht} are reached) is 3 m, also for cod.

Table 10-25 Summary of the Modelled Ranges for the 90 and 75 dB_{ht} (Species) Levels for an Operational Device with a Rotor Diameter of 24 m (taken from PTEC, 2014)

Species	90 dB_{ht} (Species)			75 dB_{ht} (Species)		
	Max Range (m)	Min Range (m)	Mean Range (m)	Max Range (m)	Min Range (m)	Mean Range (m)
Bass	<1	<1	<1	4	3	4
Cod	3	2	3	36	35	36
Dab	<1	<1	<1	<1	<1	<1
Salmon	<1	<1	<1	<1	<1	<1
Elasmobranch	<1	<1	<1	<1	<1	<1

179. For the MeyGen project, the behavioural impact ranges of fish were modelled for the operational noise predicted to be emitted from a 1 MW and 2.4 MW turbine. Operational noise was predicted to be up to 177 dB SPL_{RMS} for a 2.4 MW turbine, with peak energy content below 100 Hz but also significant peaks in the 1,500 Hz and 5,000 Hz bands (Subacoustech, 2019).

180. The operational noise from a single turbine of either size was predicted to cause a behavioural impact within 1 m of the source only (for both 90 dB_{ht} and 75 dB_{ht} metrics). The PTEC (2014) report modelled that for their fully deployed site (30 MW) the noise level "will generally be 130-150 dB re 1 uPa".

181. The exact cumulative noise produced by a fully deployed tidal demonstration zone (240 MW) is currently unknown. Although the modelling undertaken at PTEC is indicative of the scale of deployment anticipated by the Project for each single array deployment within the overall 240MW, the overall cumulative noise is expected to be greater.

182. The level of potential impact of operational noise is assessed in the context of background noise and natural variation. The level of noise predicted to be produced by the fully deployed PTEC site (130-150 dB re 1 uPa) was within the natural variation in background levels of the site (average of 120 dB re 1 μPa, and regularly exceed 130 dB re 1 μPa; PTEC, 2014). The background levels were measured from the PTEC site situated off southern Isle of Wight in the English Channel, an area exposed to heavy shipping traffic. As a result, they concluded a low magnitude for effect.

183. Four underwater noise monitoring stations were installed in the MDZ by SEACAMS (University of Bangor) to record background noise and assess variation on a daily and tidal cycle basis (Subacoustech, 2019). Underwater noise measurements were taken over periods of 15-30 days in 2016, 2017 and 2018.

184. Analysis of the records revealed that noise levels were highly consistent between sites and years; all were between 89 dB to 107 dB SPL_{RMS} re 1 µPa. As expected there was variation in the noise levels with the position of the tide, and when marine traffic was present.

185. Ambient noise levels have also been determined for the nearby Wylfa Newydd Development Area. Ambient underwater sound pressure levels were acquired between 2013 and 2014 to establish a baseline level of noise in the vicinity of Cemlyn Bay, Cemaes Bay and the Wylfa Newydd Development Area (see **Chapter 12, Marine Mammals**). The analyses reported that existing natural background noise levels for the area were between 111.4 dB re 1 µPa (SPL_{RMS}) and 120.9 dB re 1 µPa (SPL_{RMS}) (based on all transects measured).

186. It is considered that the main component to ambient noise in the MDZ is “shore noise”, though there was also influence of shipping noise to the north of the site (QinetiQ, 2005). In addition, due to the highly tidal nature of the site and the anticipated low levels of anthropogenic noise, tidal flow noise may also be a major component of the background noise levels in the MDZ (Merchant et al., 2016).

187. Due to the combination of potentially greater operational noise produced and lower background noise levels it can be expected that the magnitude of effect will be higher than that concluded in the PTEC report. Following the generic guidelines presented for the determination of magnitude of effect in **Chapter 5**, **EIA Methodology**, the magnitude of effect of underwater noise falls into the category of medium. The noise levels would constitute a minor alteration to the environment, occur on the long-term scale (i.e. duration of project, 37 years) though be reversible (once operations had stopped).

188. Whilst making consideration of the definitions for magnitude of effect, it is important to note that the zone of influence of noise generated during operation will have a limited spatial extent in the context of the wider habitat available to receptor species within the Irish Sea. As a result, based on expert judgement, it is concluded that the magnitude of effect of operational noise is low. This follows the rationale based in the PTEC assessment, which concluded low magnitude based on the very limited spatial range of the effect.

189. The most sensitive species to noise is the hearing specialists such as those in the herring family, which are considered as having a medium sensitivity to noise.

190. As a result of the low magnitude of the effect in coupled with the medium sensitivity of the receptor there is a **minor adverse** impact on fish and shellfish receptors during the operational phase via device noise.

191. With respect to repowering, the worst case scenario for underwater noise production as determined for the construction phase can also be applied to any repowering phase as similar sub-activities (installation, vessel presence) can be assumed.

192. As only 50 % of the berths will be subject to repowering, the magnitude of effect will be lower than for the main construction phase, due to a shorter time period of noise effects.

193. Therefore, in accordance with the assessment for construction and the short(er) term temporal scale of effect from repowering works, the magnitude of the effect is classified as low, the receptor sensitivity is considered medium, resulting in an impact significance that is **minor adverse**.

10.6.5.1.1. Mitigation

194. No mitigation measures are considered to be required.

10.6.5.1.2. Residual Impact

195. The residual impact is **minor adverse**.

10.6.5.2. Operational Impact 2: Permanent Habitat Loss via Project Infrastructure (including repowering)

196. The worst-case scenario for permanent habitat loss via initial installation of project infrastructure is 2,180,072 m^2; (2.18 km^2), plus an additional 52,504 m^2 via repowering of up to 50 % of the berths (see **Table 10-20**).

197. The worst-case scenario footprint accounts for 5 % of the 39.76 km^2 area covered within the study area. This is based on the assumption that all areas where infrastructure is placed would be “lost” as habitat during the operational phase (in practice, project infrastructure deployed over the lifetime of the project, such as anchor blocks and/or surface-laid cables will itself represent new habitat. However, for fish and shellfish, loss of existing habitat which currently provides foraging/spawning/nursery habitat is the focus of this assessment).

198. The exact layout of project infrastructure is currently unknown; therefore, it is not possible to make any specific conclusions on the specific habitat lost due to the location of infrastructure. The predominant seabed habitat type within the MDZ (as outlined in **Chapter 7, Metocean Conditions and Coastal Processes**) includes gravelly sand and sandy gravels, with large areas of exposed bedrock, and areas of sand and outcropping bedrock. There are also small areas of mobile sands with features of possible biogenic interest, areas of boulders and surface mobile sands.

199. The biotopes present within the export cable corridor include very tide-swept faunal communities, mixed faunal turf communities, circalittoral coarse sediment, and sublittoral sands and muddy sands (Ocean Ecology, 2018). As stated in **Chapter 9, Benthic and Intertidal Ecology** the habitats and associated benthic communities found in the study area are typical of those found in Anglesey and wider Welsh coastal regions.

200. As discussed previously, any loss of habitat for spawning and nursery grounds will be not be of significance as they are typically widespread throughout the surrounding regional waters.

201. Following the generic guidelines presented for the determination of magnitude of effect in **Chapter 5, EIA Methodology**, the magnitude of effect of habitat loss falls into the category of medium. Habitat loss would constitute a minor loss of the environment (5 % of available habitat in the MDZ), occurring on the long-term scale (i.e. duration of project, 37 years) though be reversible (once infrastructure removed).

202. Whilst making consideration of the definitions for magnitude of effect, it is important to note that the amount of habitat lost during operation will have a very limited spatial extent in the context of the wider habitat available to receptor species within the Irish Sea. Furthermore, there is evidence that habitat will not be completely lost as the infrastructure may be colonised by shellfish species (Langhamer and Wilhelmsson (2009), as cited in PTEC (2014)). As a result, based on expert judgement, it is concluded that the magnitude of effect of habitat loss during operations is low.

203. The same species used for the sensitivity assessment for habitat loss during the construction phase have been used for habitat loss for the operational and maintenance phase, specifically the blue/common mussel and European spiny lobster.

204. The blue/common mussel has a moderate sensitivity substratum loss and such changes are considered not relevant to the European spiny lobster. As a precautionary measure the maximum sensitivity to habitat loss for the receptor is concluded as medium.

205. As a result of the low magnitude of the effect in coupled with the medium sensitivity of the receptor there is a **minor adverse** impact on the receptors during operation via permanent habitat loss. This conclusion remains valid even with the additional permanent habitat loss that would be caused by repowering works.

10.6.5.2.1. Mitigation

206. No mitigation measures are considered to be required.

10.6.5.2.2. Residual Impact

207. The residual impact is **minor adverse**.

10.6.5.3. Operational Impact 3: Physical disturbance of habitats and temporary habitat loss (cable repair and repowering)

208. As with other marine energy infrastructures, there will be a requirement for planned and unplanned maintenance activities throughout the operation phase of the Project. These activities may vary in nature, however the maintenance activities considered likely to cause disturbance impacts are cable repairs and repowering works. Repowering is defined as being ‘the removal of a tenant’s infrastructure at the end of a demonstration period and replacement with the infrastructure of a new tenant, including the removal of devices (including foundations, TECs, support/super structure, inter-array cables, hubs and monitoring equipment) and reinstallation via the original construction methods.

209. Cable repairs will result in localised and temporary disturbance of the seabed up ten times throughout the project life, each requiring around 5 days of repair work. This equates to a total of a possible 3,000 m^2 of temporary disturbance occurring due to project maintenance works throughout the project life, equal to around 0.007 % of the MDZ total area.

210. As a worst-case scenario, repowering works of 50 % of the berths is predicted, which will involve removal of existing tenant infrastructure and the re-installation of new infrastructure.

211. Based on the values in **Table 10-19**, a total area of 377,400 m^2 is predicted to be subject to additional temporary seabed disturbance via repowering. Therefore, a total of 380,400 m^2 (0.38 km^2) of seabed will be temporarily disturbed for cable repairs and repowering during the operational phase of the project. All this activity will only take place within the main MDZ array site (35 km^2), meaning that 1.1 % of the MDZ array area will be affected.

212. This amount of temporary seabed disturbance via cable repair and repowering works is slightly less than that predicted from the main installation phase which concluded an impact of minor significance. Therefore, a similar impact is predicted for these operational phase impacts.

10.6.5.3.1. Mitigation

213. No mitigation measures are considered to be required.

10.6.5.3.2. Residual Impact

214. The residual impact is **minor adverse**.

10.6.5.4. Operational Impact 4: Increased Suspended Sediment Concentrations and Sediment Deposition Loss (via repowering)

215. The repowering phase may cause increased suspended sediment concentrations and sediment deposition during both the removal and construction of infrastructure. As outlined previously, it is not anticipated that a significant amount of sediment will be added to the water column due to the high tidal energy of the site. This results in a conclusion of very low/negligible magnitude of effect.

216. The very low/negligible magnitude of effect, in combination with the previously assessed medium sensitivity of representative worst-case receptor species, results in an impact significance that is **minor adverse**.

10.6.5.5. Operational Impact 5: Barrier Effects via Project Infrastructure

217. Barrier effects to the movements of fish and shellfish through the water column can arise during the Project due to the presence of tidal devices and associated infrastructure, including mooring chains and catenaries. The worst-case scenario (arising during full site deployment) for the swept area of TEC's is predicted to be 84,500 m^2 based on seabed-mounted multiple rotor platform device types with rotors up to 27 m in diameter.

218. The perceived barrier effect however will depend on a variety of factors including the type, width, number of tidal devices, and spacing between devices and the seabed. The potential distribution of infrastructure within the project area is currently unknown, however, it is unlikely to present a complete barrier to the passage of migratory fish due to the separation distance (70 m distance in the shortest dimension).

219. Of particular concern to barrier effects are the potential impacts on migratory fish who move from the freshwater to marine environment, thereby utilising the coastal environment as a migratory route. It should be noted that limited information is present on the fine-scale migration of migratory fish species. However, the study area does not form a barrier at the mouth of any

natal rivers. Indeed, the nearest protected area for migratory fish species is in excess of 50 km away.

220. Barrier effects that may arise during the operation of the project can be considered long-term and reversible in nature, as well as causing a minor alteration in the environment. As a result, the magnitude of the effect can be classified as medium.

221. The sensitivity of migratory fish species to barrier effects is considered low. This is based upon the site's potential 'barrier effect' not being at the mouth of any natal river for migratory fish species, and the small spatial extent of the site which results in individual receptors being able to avoid it.

222. As a result of the medium magnitude of the effect in coupled with the low sensitivity of the receptor there is a **minor adverse** impact on the receptors during operation.

10.6.5.5.1. Mitigation

223. No mitigation measures are considered to be required.

10.6.5.5.2. Residual Impact

224. The residual impact is **minor adverse**.

10.6.5.6. Operational Impact 6: Collision Risk

225. Collision risks can arise from fish and shellfish coming into contact with the devices. The area within which collision risk can occur is equivalent to the maximum swept area (84,500 m^2). However, it is not possible to determine the distance from the device at which entrainment may occur and result in collision risk, due to the lack of information and varied factors that can affect this parameter (e.g. species-specific avoidance as a function of swim speed, visual and auditory acuity amongst other factors, rotor structure, speed and visibility, etc.)

226. There is limited information available on the interaction of this risk and fish species. This assessment uses information from ABPmer (2010) report entitled "Collision Risk of Fish with Wave and Tidal Devices".

227. There are four factors which affect the likelihood of collision risk: exposure, long-range avoidance, close-range evasion, and collision damage (ABPmer, 2010). Exposure is based on likelihood of overlap between the fish and device based on the ecology of the fish. Long-range avoidance is based on the potential of the fish to detect the operational noise of the device. Close-range evasion is based on the potential of the fish to visually detect the device. Collision damage is based on the likely consequence of collision on the fish.

228. It is very difficult to assess the maximum sensitivity of the fish species to the effect. The worst-case scenario would assume that a fish species would overlap the device, would not be able to audibly detect the device (e.g. due to low hearing sensitivity), and are unable to conduct close-range evasion (due to insufficient burst swimming speeds). Fish behaviour when presented with a tidal turbine is unknown; however, the predicted maximum (average) rotor tip speed (22 m/s for small rotors) is above the threshold for which there is a significant risk of

physiological damage (10-12 m/s; ABPmer, 2010), therefore it can be assumed that the worst-case result of a collision will be mortality.

229. According to ABPmer (2010), the worst-case scenario for ability to avoid collision risk based on the different levels of avoidance are as follows:

- Long-range avoidance – ability to undertake this may (in a worst-case scenario) be <u>very low</u> i.e. long-range avoidance shown at distances of 10 m where close-range evasion begins. Predicted for all species that have low sensitivity to noise. Only assessed for horizontal axis turbine;

- Close-range evasion – ability to undertake this may (in a worst-case scenario) be <u>medium</u> i.e. most fish should be able to exhibit an evasion response although some strikes are possible. This is predicted for all species groups and tidal turbine combination; and

- Physiological damage – risk of physiological damage may (in a worst-case scenario) be <u>medium-high</u> i.e. moderate-high risk of physiological damage and/or mortality to some individuals. This is predicted for all species taking into account collision with the blade tip (i.e. the fastest segment).

230. Based on the findings of ABPmer (2010) that the worst-case scenario is a medium avoidance ability, i.e. it has some tolerance to avoid the impact, it is considered that the sensitivity of the receptor is low. The confidence in this assessment is low, reflecting the low confidence in the findings of ABPmer (2010).

231. It is very hard to assess the magnitude of the effect due to the absence of information. However, it can be assumed that if fatal collisions do occur, it is likely to only be to a small proportion of individuals and not result in a population-level effect. The loss of individuals, in the context of the total loss of individuals for a population, is considered to be within the natural levels of mortality due to other factors, therefore the magnitude of the effect at a population is considered to be very low/negligible.

232. According to the impact matrix the combination of a low sensitivity and a very low/negligible magnitude results in a negligible impact significance. However, due to the uncertainty over this assessment, the impact significance has been augmented to **minor adverse** as a precautionary measure.

10.6.5.6.1. Mitigation

233. No mitigation measures are considered to be required.

10.6.5.6.2. Residual Impact

234. The residual impact is **minor adverse**.

10.6.5.7. Operational Impact 7: Electromagnetic Fields

235. Electromagnetic fields (EMF) can arise in the immediate vicinity of electrical cables. The Project will include a maximum of 248 km of cable around which EMF can arise, with an overall footprint of 43,337 m^2 (see **Table 10-20**). Most turbines will export grid compliant power at 11 kV, though some may be 24 kV or 33 kV longer term. Note that the seabed cables will be covered with protection systems which will decrease the likelihood of overlap of EMF with fish and shellfish species occurrence.

236. The strength of EMF produced depends on a variety of environmental factors including strength of the magnetic (B) field, distance from cable, speed and direction of water flow, and to a lesser extent the chemical composition of the surrounding water (PTEC, 2014). Most of the cables in the Project will export at 11 kV, however the worst-case scenario is 33 kV.

237. This is within the lower range of voltage typically used for offshore windfarms (33-66 kV), for which it is currently industry practice to not conclude significant effects from EMF. Based on the predicted low voltage, the small spatial coverage of the cables, and the use of cable protection, it is predicted that the magnitude of EMF will be low.

238. There is limited information on the effect of EMF on fish and shellfish receptors. Certain groups of fish such as elasmobranchs, salmonids and eel use electromagnetic fields for key functions such as navigation and prey detection (PTEC, 2014), therefore it is possible that an alteration in the natural levels of EMF may affect these functions. Both avoidance and attraction responses have been reported to different extents for different species, making it difficult to generalise the response and infer the significance.

239. The majority of fish and shellfish species that utilise the study area are flexible in their habitat use. The worst-case scenario of complete exclusion from the area due to anthropogenic EMF and subsequent relocation to areas nearby of similar habitat function would not have a likely impact at the population level of most species.

240. However, of concern would be the potential impacts on migratory fish, as a change to their migration routes could lead to effects on the local population. Atlantic salmon and sea trout are unlikely to encounter areas of elevated EMF as they swim in the upper water column, away from the seabed cables.

241. In the unlikely event of encountering areas of increased EMF, it is considered unlikely to affect their navigation to natal rivers as this relies principally on their sense of smell. European eel have been shown to continue on their migratory paths over subsea export cables for offshore wind farms carrying a significantly higher voltage than can be expected for this Project (Westerberg and Lagenflet, 2008). It is therefore considered that effects of EMF on migratory fish will be negligible at a population level, taking into account the position of the site away from the mouth of any natal rivers.

242. Also of concern is the potential effects on the nearshore migration of shellfish species, particularly those that are of commercial importance or come to the nearshore to breed. OSPAR (2009) reported observations that marine species such as crab showed no impact on their migratory routes from the presence of subsea cables in the Baltic Sea.

243. There are a limited number of preliminary laboratory tests that also show minimal behavioural changes resulting from EMF on crab species (PTEC, 2014). As a result, it can be concluded that there will be little impact on shellfish populations from anthropogenic EMF arising through the Project.

244. The sensitivity assessment of fish and shellfish to EMF during operation of the Project is concluded as low. This assessment, coupled with the low magnitude of effect, results in the potential for a **minor adverse** impact upon receptor species. This is considered sufficiently precautionary given the lack of knowledge on potential impacts on receptor species.

10.6.5.7.1. Mitigation

245. The emplacement of cable protection constitutes embedded mitigation measures in the project design. No further mitigation measures are considered to be required.

10.6.5.7.2. Residual Impact

246. The residual impact is **minor adverse**.

10.6.6. Potential Impacts During Decommissioning

247. It is likely that decommissioning of individual structures will be the responsibility of the individual structures, as overseen by Mentor Môn. Decommissioning of the site comprises the complete removal of all infrastructure associated with the tidal energy project. Offshore decommissioning methodologies would vary considerably between devices but would be expected to be similar to the construction phase in reverse. For the purpose of this chapter, it is assumed that cables are required to be removed as this represents the worst-case scenario in terms of impacts. Therefore, it can be assumed that all impacts identified as having the potential to arise during the construction phase (**Section 10.6.4**) may also occur during the decommissioning phase.

248. As the methodologies for decommissioning are expected to be similar to construction it can be assumed that the same impacts arise, specifically underwater noise, physical disturbance and temporary loss of seabed habitat, and sediment changes. The conclusion of all three of these impacts were that they would cause a **minor adverse** impact significance, therefore this can be applied to the decommissioning phase. It should be noted that this is a highly precautionary assessment as it is likely that the impacts from decommissioning will be less than those from construction (PTEC, 2014).

10.6.6.1.1. Mitigation

249. No mitigation measures are considered to be required.

10.6.6.1.2. Residual Impact

250. The residual impact is **minor adverse**.

10.6.7. Cumulative Impacts

251. A draft list of projects and plans that, together with the Project, have the potential to result in cumulative or in-combination impacts is given in **Chapter 26, Cumulative Impact and In-Combination Effects**.

252. For this Cumulative Impact Assessment (CIA) the consideration of which projects may result in cumulative or in-combination impacts on fish and shellfish receptors has been based upon the Project-specific impact assessment and expert judgement.

253. As described in this chapter, the majority of impacts on fish and shellfish associated with the Project have a spatial extent that is limited to the site and the immediate surroundings. As such it is only projects that will affect the immediate local environment that shall be screened in for consideration. A nominal buffer of ~20 km has been chosen as a worst-case maximum extent over which impacts may overlap i.e. accumulate. Any projects beyond 20 km are screened out of this CIA on the basis that they are beyond the spatial extent of impacts from the Project. In addition, any projects that do not involve any construction in the marine environment have also been screened out. The projects taken forward for this CIA are outlined in **Table 10-26**.

254. Migratory fish have the potential to be impacted at distances greater than non-migratory fish. However, as the cumulative impacts on Annex II migratory fish are assessed as part of the HRA they are not included here, but a summary is provided for context. Of the European sites screened in for assessment for migratory fish, only two (Severn Estuary/ Môr Hafren SAC and Pembrokeshire Marine/ Sir Benfro Forol SAC) had the potential to directly spatially overlap with reasonably foreseeable plans or projects being screened in for combination effects, of which the projects were:

- Greenlink Interconnector;
- Marine aggregate dredging area 531 – Tarmac and Hanson Aggregates;
- M4 Corridor around Newport (M4CaN); and
- Newport Relocation Proposals.

255. The conclusion of the HRA for migratory fish was that no significant effects are expected at a designated population level on any of the sites due to the lack of spatial (or temporal) overlap with all reasonably foreseeable plans and projects.

Table 10-26 Projects Taken Forward into the Cumulative Impact Assessment

Project name	Project Developer	Overview	Distance from the Project	Project Status (as of July 2019)
Wylfa Decommissioning	Magnox Limited	Decommissioning of the Existing Power Station. The project is currently in a defueling phase, which will be followed by site care and maintenance, then decommissioning and final site clearance. Decommissioning understood as likely to be between 2015 and 2025. It is understood that the only marine works will be the explosive demolition of the cooling water jetty and offshore structures	17.5 km	Operational
Wylfa Nuclear Power Plant	Horizon Nuclear Power	Construction of a new nuclear power station. As part of the components there will be the disposal of dredged material at the “Holyhead North” dredge disposal site. Note that work on the project has been suspended since January 2019 for commercial reasons	17.5 km	Pre-consent
Amlwch LNG	Amlwch LNG (previously Cantaxx)	Project involves importing liquid gas to a mooring 3 km from the Amlwch coast and then transference of the gas by an undersea pipeline. Consent for this project was renewed in 2013, though the timescales of future plans are unclear	20.5 km	Consented
Holyhead Deep – 10 MW project	Minesto	10 MW Tidal kite installation plus associated onshore elements. A Marine Licence to build the first 0.5 MW installation was granted in April 2017. There is currently one device in the water. ES and HRA available: http://minesto.com/projects/holyhead-deep.	<2 km	Consented
Holyhead Deep – 80 MW project	Minesto	The Project includes construction, installation, commissioning, operation and maintenance, and decommissioning activities for an array of up to 160 DGUs (80 MW). The DGUs will be installed in clusters of between six and seven DGUs, with each DGU linked to a Deep Green Connection Hub (DGCH) via a subsea umbilical. Energy generated by the DGUs will be transmitted to the DGCH, before being ‘stepped-up’ on its way to the transmission infrastructure, a process whereby the voltage of the electricity is modified to reduce transmission losses. Each of the DGUs will require its own subsea foundation, utilising one of three options: a concrete gravity base structure, a monopile, or a mud mat foundation. Onshore aspects not discussed, intention to develop transmission infrastructure with Morlais Project.	<2 km	Pre-application

256. The main potential cumulative and in-combination impacts from the combination of projects are:

- Underwater noise;
- Physical disturbance of habitats and habitat loss; and
- Increased suspended sediment concentration and sediment deposition.

257. Each of these impacts can arise during multiple phases of the Project. Therefore, the worst-case scenario for each impact, across phases, was taken into consideration for a single assessment per impact pathway.

258. Collision risk was screened out from cumulative and in-combination effects as these can only occur within the footprint of the Project, for which there are no overlaps.

259. Barrier effects (from the emplacement of infrastructure in the water column) were screened out from cumulative and in-combination effects as there is no adjacent project which has infrastructure in the water column that may affect fish and shellfish receptors (see below for rationale behind screening out Holyhead Deep).

260. Similarly, EMF has been screened out from cumulative and in-combination effects as the two Wylfa projects and the Almwch LNG do not involve emplacement of electric cables in the marine environment, and Holyhead Deep has no pathway for impacting fish and shellfish receptors (see below).

261. It should be noted that, although Holyhead Deep project co-occurs with the current Project, any impacts on fish species was ruled out from the Holyhead Deep 10 MW project as the "*nature of device deemed of very low impact to fish ecology*". There is no further detail on the Holyhead Deep 80MW project at the time of writing. However, as there are no primary impacts on fish and shellfish expected to arise from this project, there is no pathway for cumulative or in-combination effects to arise with the current Project.

262. At the time of writing it was not possible to find out any more information on the proposed Almwch LNG project. A period of more than five years has elapsed since the consent for this project was renewed yet there has been no recent information released and available online. It is therefore not possible to assess the potential cumulative and in-combination impacts between this project and the current Project at this time.

10.6.7.1. Cumulative Impact 1: Underwater Noise

263. The production of underwater noise from the Wylfa decommissioning project will only arise during the potential explosive decommissioning of the cooling water jetty and associated infrastructure. The underwater noise produced by explosive detonations is typically of high intensity and short duration (<1 second). The noise from underwater explosions in itself can cause mortality in the immediate area and effects at a range of up to 350 m. There is little information on the sub-lethal impacts in fish from explosions. Due to the short temporal scale (single explosion per piece of infrastructure) of the underwater noise produced during the Wylfa decommissioning it is considered unlikely to cause any added impact above the level of impact that may arise during the Project.

264. Marine works associated with the construction of Wylfa Nuclear Power Plant will include both permanent and temporary works. The Project Description states that "*the majority of works will be undertaken within the first two years of the Project's construction phase, though certain works may take up to five years to complete*". As the project is in suspension it is uncertain when or if these works will occur. The Project Description has identified the activities that may generate underwater noise as including drilling, piling (vibratory piling hammer), dredging, rock breaking, vessel noise. Of these, it can be expected that piling using the hydraulic drop hammer would produce the greatest amount of underwater noise. It has not been possible to ascertain any ranges of underwater noise impacts from the construction activities from Wylfa Nuclear Power Plant. If it can be assumed that the piling will produce underwater noise of a similar level to that produced by the current Project, then there is no pathway for overlap of the zone of influence of underwater noise. Indeed, even if the noise levels were higher, it is deemed highly unlikely that the zone of influence would exceed the 17.5 km distance between the two projects.

265. Furthermore, the deposition of dredge material at the Holyhead North dredge site as part of the Wylfa Newydd project will also produce underwater noise. Little is known about the underwater noise generated from deposition at sea therefore as a worst-case scenario the sound levels from cutter suction dredging were used in the Horizon Nuclear Disposal site characterisation report. For the sound levels produced by cutter suction dredging, the maximum range for injury to fish was modelled to be 2 m, and the maximum range of TTS was 13 m. Based on these distances there is no spatial overlap of the acoustic zones of influence produced by the two projects.

266. It is not known when the activities creating underwater noise from the other Projects will occur. Therefore, for the purpose of this assessment, the worst-case scenario of complete temporal overlap between the noise-producing activities of the identified projects and each phase of the Project has been assumed.

267. Following the measurements given above, and taking into account the maximum impact range of worst-case noise produced during the Project activities (50 m, during construction; see **Table 10-24**), it can be concluded that there will be no overlap between the acoustic footprints of the Project with other projects and plans in the area. Furthermore, the footprint over which there will be elevated noise levels is small and represents only a small portion of the greater area available to fish and shellfish species. Therefore, the cumulative impacts from the underwater noise pathway are considered not significant.

10.6.7.2. Cumulative Impact 2: Physical Disturbance and Habitat Loss

268. Another potential cumulative and in-combination impact between the Project and other projects and plans is the physical disturbance and habitat loss. The current Project represents 2,184,932 m^2 (2.18 km^2) of permanent habitat loss during the lifetime of the Project in addition to temporary habitat loss which is anticipated to have a maximum total of 423,499 m^2 (0.42 km^2) during each of the construction and decommissioning phase, and 127,000 m^2 (0.12 km^2) during the operational phase.

269. The seabed footprint of marine infrastructure associated with the existing Power Station at Wylfa is very small as it comprises a single jetty not more than 150 m long. The marine works as part of the construction of the Wylfa Newydd project are in a similar location, adjacent to the coast

at Wylfa on the north Anglesey coast, and are also considered small (extending a maximum of 3 km into the marine zone). Due to the small area and distance from the site it is considered that the cumulative impact of habitat disturbance and loss from these project activities on north Anglesey will have a negligible effect.

270. In addition to construction the Wylfa Newydd project involves dredge disposal at a large site nearer to the MDZ. As part of the plume dispersion modelling, a worst-case scenario of maximum extent of deposition on the seabed (at a thickness of 1 cm) was a total area of 1.8 km^2. This value can also be utilised to represent the maximum habitat loss in the area.

271. In comparison to the amount of comparable habitat identified in the survey area, the overall area of habitat that will be impacted by the additional seabed activities will be small and it is predicted that no significant cumulative impacts should occur.

10.6.7.3. Cumulative Impact 3: Increased Suspended Sediment Concentrations and Sediment Deposition loss

272. The decommissioning work of the existing Wylfa Power Station that are in the marine environment, i.e. the explosive demolition of the jetty, has been identified as having the potential to result in "*substantially elevated levels of suspended sediment in the water column, possibly resulting in smothering of sensitive habitats and species*". NRW that sediment transport modelling be conducted to predict effects, although it is uncertain if this was undertaken and no evidence of this has been found online.

273. As part of the Environmental Statement produced for the application for the Wylfa Newydd Project a detailed assessment of the sediment regime in the area was undertaken. The results can be used to inform the potential extent of impacts from the decommissioning activity of the existing Wylfa Power Station as they are in the same location.

274. The Environmental Statement details that, despite the high amount of wave energy, "*sediment movement is essentially limited to individual bays as rock platforms and headlands provide barriers (natural groynes)*" this prevents the movement of sediment. On this basis it is possible to infer that any increased sediment suspension as a result of marine activities in the Wylfa area will not extend as far as the Morlais zone, which is situated 17.5 km away.

275. Dredge disposal at the Holyhead North/Deep site as part of the Wylfa Newydd project also has the potential to cause localised increase in sediment concentrations and deposition. Modelling of the environmental change and effects on fish and shellfish lead to a conclusion of negligible magnitude, a worst-case medium sensitivity of the receptor (due to commercial fish), and therefore an overall negligible impact due to increased suspended sediment concentration. Similarly, the report concluded a negligible effect on fish and shellfish receptors from smothering due to the negligible magnitude of effect (due to mortality or displacement) and the medium value/sensitivity of the receptor. It was expected that all resuspended sediment would remain wholly contained within the disposal site.

276. Due to the minor adverse impact of increased sediment resulting from the Project, coupled with the negligible effect of the sediment pathways on fish and shellfish concluded from the only nearby project, and the lack of spatial overlap of effects, it can be concluded that the cumulative impacts from increased sediment will not be significant.

10.6.7.4. Cumulative Impact Summary

277. In summary, significant cumulative impacts are not expected from the Project in combination with any other reasonably foreseeable plans or projects in the study area. This is applicable throughout the lifecycle of the Project, as the key impact pathways may arise during all phases (construction through to decommissioning).

10.6.8. Inter-Relationships

278. **Table 10-27** lists out the inter-relationships between this chapter and other chapters within the ES.

Table 10-27 Inter-Topic Relationships

Topic and description	Related Chapter	Where addressed in this Chapter	Rationale
Marine Sediment and Water Quality	Chapter 8	Section 10.5.7.3	Both chapters consider the potential effects of the project on the European Shellfish Water designation.
Benthic and Intertidal Ecology	Chapter 9	Section 10.6.1 and 10.6.5	Both chapters consider the potential effects of the project in an assessment of the impact of invasive non-native species.
Marine Mammals	Chapter 12	Section 10.5.2	Noted that cetaceans may predate on species listed in this chapter; both chapters consider the effects of the project on the prey species directly or as a proxy
Marine Ornithology	Chapter 11	Section 10.5.2	Noted that birds may predate on species listed in this chapter; both chapters consider the effects of the project on the prey species directly or as a proxy
Commercial Fisheries	Chapter 14	Section 10.5.2 and 10.5.3	Noted that commercial fisheries utilise some of the species of fish listed in this chapter; both chapters consider the effects of the project on the fish species directly or as a proxy

10.6.9. Interactions

279. The impacts identified and assessed in this chapter have the potential to interact with each other, which could give rise to synergistic impacts as a result of that interaction. The worst case impacts assessed within the chapter take these interactions into account and for the impact assessments are considered conservative and robust. For clarity the areas of interaction between impacts are presented in **Table 10-28**, along with an indication as to whether the interaction may give rise to synergistic impacts.

Table 10-28 Potential Interaction Between Impacts

Potential interaction between impacts						
Construction/ Repowering/ Decommissioning	1: Underwater noise		2: Physical disturbance of habitats and temporary habitat loss		3: Increased suspended sediment concentration and sediment deposition	
1: Underwater noise	-		Yes		No	
2: Physical disturbance of habitats and temporary habitat loss	Yes		-		Yes	
3: Increased suspended sediment concentration and sediment deposition	No		Yes		-	
Operation	Impact 1: Underwater Noise	Impact 2: Long-term habitat loss	Impact 3: Barrier effects	Impact 4: Increased suspended sediment concentration and sediment deposition	Impact 5: Collision risk	Impact 6: Electromagnetic fields
Impact 1: Underwater Noise	-	Yes	Yes	No	No	No
Impact 2: Long-term habitat loss via placement of project infrastructure (project footprint)	Yes	-	Yes	Yes	Yes	Yes
Impact 3: Barrier effects	Yes	Yes	-	Yes	Yes	Yes
Impact 4: Increased suspended sediment concentration and sediment deposition	No	Yes	Yes	-	Yes	Yes
Impact 5: Collision risk	No	Yes	Yes	Yes	-	No
Impact 6: Electromagnetic fields	No	Yes	Yes	Yes	No	-

10.7. SUMMARY

280. **Table 10-29** presents a summary of the impact assessments undertaken for fish and shellfish receptors in this chapter. Throughout the construction, operation and maintenance, repowering, and decommissioning phases, the impact on fish and shellfish is considered to be of **minor adverse** significance.

Table 10-29 Potential Impacts on Fish and Shellfish Receptors

Phase	Potential Impact	Receptor	Value / sensitivity combined	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
Construction	Impact 1: Underwater noise	All fish species	Medium	Low	Minor adverse	None proposed	Minor adverse
	Impact 2: Physical disturbance of habitats and temporary habitat loss	All fish and shellfish species	Low	Low	Minor adverse	None proposed	Minor adverse
	Impact 3: Increased suspended sediment concentration and sediment deposition	All fish and shellfish species	Medium	Very low	Minor adverse	None proposed	Minor adverse
Operation and Maintenance	Impact 1: Underwater Noise Effects via (a) device operational noise and (b) repowering works	All fish species	Medium	Low	Minor adverse	None proposed	Minor adverse
	Impact 2: Long-term habitat loss via placement of project infrastructure (project footprint) (and via repowering)	All fish and shellfish species	Medium	Low	Minor adverse	None proposed	Minor adverse
	Impact 3: Physical disturbance of habitats and temporary habitat loss (repowering only)	All fish and shellfish species	Medium	Low	Minor adverse	None proposed	Minor adverse
	Impact 4: Increased suspended sediment concentration and sediment deposition (repowering only)	All fish and shellfish species	Medium	Very low	Minor adverse	None proposed	Minor adverse
	Impact 5: Barrier effects	All fish and shellfish species	Low	Medium	Minor adverse	None proposed	Minor adverse

Phase	Potential Impact	Receptor	Value / sensitivity combined	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
	Impact 6: Collision risk	All fish and shellfish species	Low	Negligible	Minor adverse	None proposed	Minor adverse
	Impact 7: Electromagnetic fields	All fish and shellfish species	Low	Low	Minor adverse	None proposed	Minor adverse
Decommissioning	Impact 1: Underwater noise	All fish species	Medium	Low	Minor adverse	None proposed	Minor adverse
	Impact 2: Physical disturbance of habitats and temporary habitat loss	All fish and shellfish species	Low	Low	Minor adverse	None proposed	Minor adverse
	Impact 3: Increased suspended sediment concentration and sediment deposition	All fish and shellfish species	Medium	Very low	Minor adverse	None proposed	Minor adverse

TABLE OF FIGURES (VOLUME II)

TABLE OF APPENDICES (VOLUME III)

GLOSSARY OF ABBREVIATIONS

Acronym	Term
BDMPS	Biologically Defined Minimum Population Size
BoCC	Birds of Conservation Concern
CEMP	Construction and Environment Management Plan
CFP	Common Fisheries Policy
CIEEM	Chartered Institute of Ecology and Environmental Management
CPGR	Counterfactual of Population Growth Rate
CPS	Counterfactual of Population Size
CRM	Collision Risk Modelling
DECC	Department of Energy and Climate Change
ECC	Export Cable Corridor
EcIA	Ecological Impact Assessment
EIA	Environmental Impact Assessment
EMEC	European Marine Energy Centre
ERM	Encounter Rate Modelling
ES	Environmental Statement
EU	European Union
JNCC	Joint Nature Conservation Committee
MDZ	Morlais Development Zone
MMO	Marine Management Organisation
MW	Megawatt
NERC	Natural Environment and Rural Communities
NPS	National Policy Statement
NRW	Natural Resources Wales
NSIP	Nationally Significant Infrastructure Project
OfDA	Offshore Development Area
PVA	Population Viability Analysis
RSPB	Royal Society for the Protection of Birds
SAC	Special Area of Conservation
SMP	Seabird Monitoring Programme
SNH	Scottish Natural Heritage
(p)(d)SPA	(proposed) (draft) Special Protection Area
SSSI	Site of Special Scientific Interest
TEC	Tidal Energy Converter
TWG	Technical Working Group
UK SNCBs	United Kingdom Statutory Nature Conservation Bodies
ZoI	Zone of Influence

GLOSSARY OF TERMINOLOGY

Density dependent	Where population growth rates are regulated by the density of a population.

Density independent	Where the growth of a population does not depend on the population density.
Deterministic	Where the values for the dependent variables of the system are completely determined by the parameters of the model.
Offshore Development Area	Morlais Demonstration Zone (MDZ) and Export Cable Corridor (ECC) combined.
Stochastic	Having a random probability distribution or pattern that may be analysed statistically but may not be predicted precisely.

11. MARINE ORNITHOLOGY

11.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) considers the potential impacts of the proposed Morlais project (the Project) on marine ornithology. It provides an overview of the existing baseline environment in respect to marine ornithology within a Zone of Influence (ZoI) around relevant elements of the Project. An Ecological Impact Assessment (EcIA) of the potential impacts of construction, operation / repowering, and decommissioning of the Project based on this baseline environment is then provided. This EcIA also considers transboundary impacts and cumulative impacts of existing and proposed projects in respect of marine ornithology.

2. The Project also has the potential to impact terrestrial ecology, marine mammals and fish receptors. These potential impacts are covered in **Chapter 19, Onshore Ecology** (which also covers terrestrial ornithology), **Chapter 9, Benthic and Intertidal Ecology**, **Chapter 10, Fish and Shellfish Ecology** and **Chapter 12, Marine Mammals**. A range of indirect impacts on marine ornithology receptors are possible; information from Chapter 9, Chapter 10 and Chapter 12 has been used to support assessments of those impacts where relevant.

3. This chapter has been prepared by Royal HaskoningDHV, supported by two years of boat-based ornithological surveys undertaken for the Project by Natural Power.

4. A Habitats Regulations Assessment (HRA) has also been compiled separately to determine whether the Project has the potential to have an adverse effect on the integrity and features of Natura 2000 sites (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).

11.2. POLICY, LEGISLATION AND GUIDANCE

11.2.1. Legislation

5. An overview of the relevant legislative context for the Project is provided in **Chapter 2, Policy and Legislation**.

6. Legislation relevant to marine ornithology is identified in **Table 11-1** along with a summary of relevant measures derived from it.

Table 11-1 Summary of Legislation and Relevant Measures

Legislation	Relevant Measures
Birds Directive - Council Directive 2009/147/EC on the Conservation of Wild Birds	This Directive provides a 'General System of Protection' for all species of naturally occurring wild birds in the EU. The most relevant provisions of the Directive are the identification and classification of Special Protection Areas (SPAs) for rare or vulnerable species listed in Annex I of the Directive and for all regularly occurring migratory species (required by Article 4). It also establishes a general scheme of protection for all wild birds (required by Article 5). The Directive requires national Governments to establish SPAs and to have in place mechanisms to protect and manage them. The SPA protection procedures originally set out in Article 4 of the Birds Directive have been replaced by the Article 6 provisions of the Habitats Directive. The UK has triggered article 50 of the Treaty of European Union and is currently in the process of withdrawing from the European Union (EU). Recent UK Government Guidance

Legislation	Relevant Measures
	(September 2018) states that 'The EU Withdrawal Act 2018 will ensure all existing EU environmental law continues to operate in UK law, providing businesses and stakeholders with certainty as we leave the EU.'
Wildlife and Countryside Act 1981, as amended	The Wildlife and Countryside Act 1981 (as amended) is the principal mechanism for the legislative protection of wildlife in Great Britain. It provides protection for all species of wild birds and their nests and establishes the system of Sites of Special Scientific Interest (SSSI).
The Conservation of Habitats and Species Regulations 2017	The Conservation of Habitats and Species Regulations 2017 (hereafter called the 'Habitats Regulations'), transposes the Birds Directive and the Habitats Directive into national law in the onshore environment and territorial waters out to 12 nautical miles, operating in conjunction with the Wildlife and Countryside Act 1981. The Habitats Regulations place an obligation on 'competent authorities' to carry out an appropriate assessment of any proposal likely to affect a SAC or SPA, to seek advice from Statutory Nature Conservation Bodies (SNCBs), in this case Natural Resources Wales (NRW), and to not approve an application that would have an adverse effect on the integrity of a SAC or SPA (except under very tightly constrained conditions).
The Environment (Wales) Act 2016	This Act replaces Section 40 and Section 42 in the Natural Environment and Rural Communities (NERC) Act 2016. It enables the planning and management of Wales' natural resources in a more proactive, sustainable and joined up way. The Section 7 List of Species and Habitats of Principal Importance for Conservation of Biological Diversity in Wales is used as an input to determine the value of marine ornithology receptors.
The Wellbeing of Future Generations (Wales) Act 2015	The Act establishes seven wellbeing goals, the second of which "A resilient Wales" is described as "*A nation that maintains and enhances a biodiverse natural environment with healthy functioning ecosystems that support social, economic and ecological resilience and the capacity to adapt to change (for example climate change)*."

11.2.2. Guidance

7. The impact assessment has been prepared with reference to the following guidance:

- CIEEM, 2018. Guidelines for Ecological Impact Assessment in the UK and Ireland. CIEEM, Winchester (CIEEM, 2018);
- SNH, 2016. Assessing collision risk between underwater turbines and marine wildlife (Guidance note). Scottish Natural Heritage (SNH, 2016); and
- UK SNCBs, 2017. Joint SNCB Interim Displacement Advice Note: Advice on how to present assessment information on the extent and potential consequences of seabird displacement from offshore wind farm developments (UK SNCBs, 2017).

11.2.3. Policies and Plans

8. National (UK and Wales) planning policy relevant to marine ornithology is identified in **Table 11-2** along with a summary of relevant measures derived from it.

Table 11-2 Summary of National (UK and Wales) Policies, Plans and Relevant Measures

Legislation	Relevant Measures
Overarching National Policy Statement (NPS) for Energy (NPS	Paragraph 5.3.3 states that the Applicant should ensure that the ES clearly sets out any effects on internationally, nationally and locally designated sites of ecological or geological conservation importance, on protected species and on habitats and other species identified as being of principal importance for the conservation of biodiversity.

Legislation	Relevant Measures
EN-1) (July 2011)	Paragraph 5.3.4 states that the Applicant should also show how the proposed Project has taken advantage of opportunities to conserve and enhance biodiversity and geological conservation interests. Paragraph 5.3.18 states that the Applicant should include appropriate mitigation measures as an integral part of the proposed development.
National Policy Statement for Renewable Energy Infrastructure (NPS EN-3) (July 2011)	EN-3, taken together with the Overarching National Policy Statement for Energy (EN-1), provides the primary basis for decisions by the Infrastructure Planning Commission (IPC) on applications it receives for nationally significant renewable energy infrastructure. Paragraph 1.2.2. states that Applicants should, therefore, ensure that their applications and any accompanying supporting documents and information are consistent with the instructions and guidance in this NPS (EN-3), EN-1 and any other NPSs that are relevant to the application in question.
Planning Policy Wales (updated periodically)	The Welsh Government's objectives for conserving and improving the natural environment are: promote the conservation of landscape and biodiversity, in particular the conservation of native wildlife and habitats, ensure that action in Wales contributes to meeting international responsibilities and obligations for the natural environment, ensure that statutorily designated sites are properly protected and managed, safeguard protected species, and promote the functions and benefits of soils, and in particular their function as a carbon store' There is a clear requirement for pre-planning consent consultation with Natural Resources Wales (NRW) where a planning application or proposal may be 'likely to have a significant effect on sites of more than local importance or on a designated area' or would be 'likely to result in disturbance or harm to a protected species.' Pre-application discussions are recommended for any development proposal likely to have an effect on the wildlife of a given area whether designated or not. For example, paragraph 5.5.1 identifies that the effect of a development proposal on the wildlife 'of any area can be a material consideration' and that 'in such instances and in the interests of achieving sustainable development it is important to balance conservation objectives with the wider economic needs of local business and communities.' There is a requirement for development proposals to include reasonable steps to safeguard or enhance the environmental quality of the land should development take place. Planning Policy Wales requires local planning authorities to 'have regard to the relative significance of international, national and local designations in considering the weight to be attached to nature conservation interests and should take care to avoid placing unnecessary constraints on development.' Statutory designations do not necessarily prohibit development taking place, however, paragraph 5.5.5 states that development proposals 'must be carefully assessed for their effect' on the interests for which the designation is made. There is a presumption against development that is likely to damage a SSSI and it is noted that SSSIs can be damaged by developments that lie either within or beyond the SSSI boundaries and that this could be 'some distance away.' There is specific reference to the duty on all public bodies under the Wildlife and Countryside Act 1981 (as amended by the Countryside Rights of Way Act 2000) to further conserve and enhance the features and reasons for a SSSI being of special interest in the exercise of public body functions which includes local planning authorities. Paragraph 5.4.4. acknowledges that non-statutory designations carry less weight than statutory designations and that at a policy level, local authorities are required to be clear that a non-statutory designation does not 'preclude appropriate socio-economic activities' and if certain features or component characteristics of sites specifically need to be conserved and, as such, require additional protection, this should be explained at a policy level. Species protected under European or UK legislation are identified as a material consideration when considering a development proposal where protected species are present and if the development would 'be likely to result in disturbance or harm to the species or its habitat.' The potential need for ecological survey and assessment of likely

Legislation	Relevant Measures
	impact of a proposed development on a protected species to inform planning decisions is highlighted in paragraph 5.5.11.
TAN-5- Nature Conservation and Planning	Technical Advice Note (TAN) 5 supplements Planning Policy Wales and provides advice about how the land use planning system in Wales 'should contribute to protecting and enhancing biodiversity and geological conservation.' The TAN provides guidance to local planning authorities on: 'the key principles of positive planning for nature conservation; nature conservation and Local Development Plans; nature conservation in development management procedures; development affecting protected internationally and nationally designated sites and habitats; and, development affecting protected and priority habitats and species.' In section 2.4 when deciding planning applications that may affect nature conservation, 'local authorities should contribute to the protection and improvement of the environment…seeking to avoid irreversible harmful effects on the natural environment; ensure that appropriate weight is attached to designated sites of international, national and local importance; protect wildlife and natural features in the wider environment, with appropriate weight attached to priority habitats and species in Biodiversity Action Plans; ensure that all material considerations are taken into account and decisions are informed by adequate information about the potential effects of a development on nature conservation; ensure that the range and population of protected species is sustained; and adopt a stepwise approach to avoid harm to nature conservation, minimise unavoidable harm by mitigation measures, offset residual harm by compensation measures and look for new opportunities to enhance nature conservation; where there may be significant harmful effects local planning authorities will need to be satisfied that any reasonable alternative sites that would result in less or no harm have been fully considered.' At section 3.3.2 regarding Local Development Plans policies the guidance states that a policy should be included in respect of the application of the precautionary principle. Section 4 includes specific and detailed guidance, expanding on the principles set out in 2.4, in respect of the development control process including pre-application discussions, preparing planning applications, requests for further information and ecology in respect of EIA. The broad principles of development control requirements are set out as follows: 'adopting the five-point approach to decision-making – information, avoidance, mitigation, compensation and new benefits; ensuring that planning applications are submitted with adequate information, using early negotiation, checklists, requiring ecological surveys and appropriate consultation; securing necessary measures to protect, enhance, mitigate and compensate through planning conditions and obligation; carrying out effective planning enforcement; and identifying ways to build nature conservation into the design of new development.'
Renewable Energy Policy Wales	The 2012 Welsh Government policy document, Energy Wales: A Low Carbon Transition, updated in 2016, outlines the Welsh Government's approach to utilising the marine environment for renewable energy deployment. The Policy includes the following aim: "*we want to carefully plan and manage the relationship between energy development and our natural environment in line with the ambition of 'Sustaining a Living Wales'*."
UK Post-2010 Biodiversity Framework	The 'UK Post-2010 Biodiversity Framework' succeeds the UK Biodiversity Action Plan. The Framework demonstrates how the work of the four countries and the UK contributes to achieving the Aichi Biodiversity Targets, and identifies the activities required to complement the country biodiversity strategies in achieving the targets.
UK Marine Policy Statement (MPS)	New systems of marine planning are being introduced in the UK. The MPS, adopted under section 44 of the Marine and Coastal Access Act 2009, is the framework for developing and implementing regional Marine Plans. It will contribute to the achievement of sustainable development in the United Kingdom marine area. High level objectives are for the protection, conservation and where appropriate recovery of biodiversity; healthy, resilient and adaptable marine and coastal ecosystems across their natural range; and oceans supporting viable populations of representative, rare, vulnerable and valued species.

Legislation	Relevant Measures
Natural Environment White Paper 2011	The paper was the first White Paper produced by the government in 20 years. The paper contains plans to reconnect nature, connect people and nature for better quality of life and capture and improve the value of nature.
A Green Future: Our 25 Year Plan to Improve the Environment 2018	The plan sets out 10 goals and a range of high-level policies aimed at helping "*the natural world regain and retain good health*". The key policies within the plan relevant for this chapter are: Embedding an 'environmental net gain' principle for development, including housing and infrastructure; Protecting and recovering nature (including improving biosecurity to protect and conserve nature).

9. **Table 11-3** sets out the Marine Policy Statement (MPS) and draft Welsh National Marine Plan (WNMP) policies which are particularly relevant to Marine Ornithology.

Table 11-3 National l Policy Requirements Relevant to Marine Ornithology

Policy Description	Reference	ES Reference
MPS		
Renewable energy developments can potentially have adverse impacts on marine fish and mammals, primarily through construction noise and may displace fishing activity and have direct or indirect impacts on other users of the sea, including mariners. Certain bird species may be displaced by offshore wind turbines, which also have the potential to form barriers to migration or present a collision risk for birds. Their foundation designs are likely to have an effect on hydrodynamics and consequent sediment movement. This includes potential scouring of sediments around the bases of turbines. These and other potential adverse impacts, together with potential mitigation measures, are considered in the National Policy Statement for Renewable Energy Infrastructure (EN-3).	Section 3.3.24	Potential impacts of displacement, collision risk and entanglement are discussed in **Sections 11.6.4.2**, **11.6.5.3** and **11.6.5.4.**
Marine energy deployments, that is wave and tidal deployments, may pose potential risks to the environment if inappropriately sited. However, the level of risk and ecological significance is largely unknown since, in particular, tidal stream and wave technologies are at a relatively early stage of development. Studies of tidal range technologies, including barrages, have indicated that these structures can have adverse impacts on migratory fish and bird species and on the hydrodynamics of the estuarine environments in which they are situated. To underpin the marine planning process further research is needed to develop a better understanding of the potential impacts that marine technologies might have on potentially sensitive environmental features. For example, adaptation and mitigation methods for such impacts may be supported by detailed monitoring programmes and co-ordinated research initiatives, including post deployment of devices.	Section 3.3.25	The potential significance of displacement of birds from the Project site is assessed in **Section 11.6.5.1**.
Draft WNMP		
Proposals should demonstrate how they: · avoid adverse impacts on individual Marine Protected Areas (MPAs) and	ENV_02: Marine Protected Areas	The conservation statuses of bird species

Policy Description	Reference	ES Reference
the coherence of the network as a whole; · have regard to the measures to manage MPAs; and · avoid adverse impacts on non-marine designated sites.		present within the MDZ are presented in **Table 11-9**. Information to Support an HRA is provided in **Document MOR/RHDHV/DOC/0067, Information to Support HRA**.
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative impacts are assessed in **Section 11.6.7** and in **Chapter 26**

10. The Project is seeking consent for a Transport and Works Act Order from the Welsh Government and a Marine Licence from Natural Resources Wales (NRW). Although this Project is not seeking a Development Consent Order (DCO), its size (240 MW) means it is representative of a Nationally Significant Infrastructure Project (NSIP), therefore guidance relevant to NSIPs is considered appropriate to use for this Project. Guidance that is relevant to assessing impacts on marine ornithology for NSIPs are set out within National Policy Statements (NPSs) which are the principal decision-making documents for NSIPs. Those relevant to marine ornithology include:

- Overarching NPS for Energy (EN-1);
- NPS for Renewable Energy Infrastructure (EN-3); and
- NPS for Electricity Networks Infrastructure (EN-5) (DECC, 2011c).

11. Although NPS EN-3 states "*this NPS does not cover other types of renewable energy generation that are not at present technically viable over 50 MW onshore or over 100 MW offshore such as schemes that generate electricity from tidal stream or wave power*", the relevant requirements of EN-3 have been referred to until a revision to this NPS or a separate NPS is provided for tidal range schemes greater than 100 MW.

12. The specific assessment requirements for marine ornithology, as detailed in NPS EN-1 and EN-3, are summarised in **Table 11-4**, together with an indication of the paragraph numbers of the chapter where each is addressed. Where any part of the NPS has not been followed within the assessment, an explanation as to why the requirement was not deemed relevant, or has been met in another manner, is provided.

Table 11-4 NPS EN-1 and EN-3 Assessment Requirements

EN-1 and EN-3 Assessment Requirements	NPS Reference	ES Reference
'Where the development is subject to EIA [Environmental Impact Assessment] the applicant should ensure that the ES [Environmental Statement] clearly sets out any effects on internationally, nationally and locally designated sites of ecological or geological conservation importance, on	**NPS EN-1 Section 5.3 Paragraph 5.3.3**	**Section 11.6**

EN-1 and EN-3 Assessment Requirements	NPS Reference	ES Reference
protected species and on habitats and other species identified as being of principal importance for the conservation of biodiversity. The applicant should provide environmental information proportionate to the infrastructure where EIA is not required to help the Infrastructure Planning Commission (IPC) consider thoroughly the potential effects of a proposed project.'		
'The applicant should show how the project has taken advantage of opportunities to conserve and enhance biodiversity and geological conservation interests.'	**NPS EN-1 Section 5.3 Paragraph 5.3.4**	**Section 11.6**
'When considering the application, the IPC will have regard to the Government's biodiversity strategy as (sic) set out in 'Working with the grain of nature', which aims to halt or reverse declines in priority habitats and species; accept the importance of biodiversity to quality of life. The IPC will consider this in relation to the context of climate change. As a general principle, and subject to the specific policies below, development should aim to avoid significant harm to biodiversity and geological conservation interests, including through mitigation and consideration of reasonable alternatives (as set out in section 4.4 above); where significant harm cannot be avoided, then appropriate compensation measures should be sought. In taking decisions, the IPC should ensure that appropriate weight is attached to designated sites of international, national and local importance; protected species; habitats and other species of principal importance for the conservation of biodiversity; and to biodiversity and geological interests within the wider environment.'	**NPS EN-1 Section 5.3 Paragraph 5.3.5-5.3.8**	**Table 11-12**, **Section 11.6**
'The IPC will have the same regard to potential Special Protection Areas (pSPAs) and Ramsar sites as those sites identified through international conventions and European Directives.'	**NPS EN-1 Section 5.3 Paragraph 5.3.9**	**Document MOR/RHDHV/DOC/0067, Information to Support HRA**
'Many SSSIs are also designated as sites of international importance and will be protected accordingly. Those that are not, or those features of SSSIs not covered by an international designation, should be given a high degree of protection.'	**NPS EN-1 Section 5.3 Paragraph 5.3.10**	**Table 11-12**
'Where a proposed development on land within or outside an SSSI is likely to have an adverse effect on an SSSI (either individually or in combination with other developments), development consent should not normally be granted. Where an adverse effect, after mitigation, on the site's notified special interest features is likely, an exception should only be made where the benefits (including need) of the development at this site, clearly outweigh both the impacts that it is likely to have on the features of the site that make it of special scientific interest and any broader impacts on the national network of SSSIs.'	**NPS EN-1 Section 5.3 Paragraph 5.3.11**	**Table 11-12**, **Section 11.6**
'The IPC will have regard to sites of regional and local biodiversity and geological interest, which include Regionally Important Geological Sites, Local Nature Reserves and Local Sites when considering applications	**NPS EN-1 Section 5.3 Paragraph 5.3.13**	**Table 11-12**, **Section 11.6**

EN-1 and EN-3 Assessment Requirements	NPS Reference	ES Reference
since they are recognised to have a fundamental role in meeting overall national biodiversity targets.'		
The applicant should include appropriate mitigation measures as an integral part of the proposed development and demonstrate that: ▪ During construction, they will seek to ensure that activities will be confined to the minimum areas required for the works; ▪ During construction and operation best practice will be followed to ensure that risk of disturbance or damage to species or habitats is minimised, including as a consequence of transport access arrangements; ▪ Habitats will, where practicable, be restored after construction works have finished; and ▪ Opportunities will be taken to enhance existing habitats and, where practicable, to create new habitats of value within the site landscaping proposals.	**NPS EN-1 Section 5.3 Paragraph 5.3.18**	**Section 11.6**
'The scope, effort and methods required for ornithological surveys should have been discussed with the relevant statutory advisor'.	**NPS EN-3 Section 2.6 Paragraph 2.6.102**	**Section 11.3**
'Relevant data from operational offshore wind farms should be referred to in the applicant's assessment'.	**NPS EN-3 Section 2.6 Paragraph 2.6.103**	**Section 11.4.2 and 11.4.3**
'It may be appropriate for assessment to include collision risk modelling for certain species of birds. Where necessary, the assessments carried out by applicants should assess collision risk using survey data collected from the site at the pre-application EIA stage. The IPC will want to be satisfied that the collision risk assessment has been conducted to a satisfactory standard having had regard to the advice from the relevant statutory advisor'.	**NPS EN-3 Section 2.6 Paragraph 2.6.104**	**Appendix 11.3 (Volume III)**
'Aviation and navigation lighting should be minimised to avoid attracting birds, taking into account impacts on safety'.	**NPS EN-3 Section 2.6 Paragraph 2.6.107**	**Section 11.6.4 and 11.6.5**
'Subject to other constraints, wind turbines should be laid out within a site, in a way that minimises collision risk, where the collision risk assessment shows there is a significant risk of collision'.	**NPS EN-3 Section 2.6 Paragraph 2.6.108**	**Section 11.6.5.3**
'Construction vessels associated with offshore wind farms should, where practicable and compatible with operational requirements and navigational safety, avoid rafting seabirds during sensitive periods'.	**NPS EN-3 Section 2.6 Paragraph 2.6.109**	**Section 11.6.4. and 11.6.5**
'The exact timing of peak migration events is inherently uncertain. Therefore, shutting down turbines within migration routes during estimated peak migration periods is unlikely to offer suitable mitigation'.	**NPS EN-3 Section 2.6 Paragraph 2.6.110**	**Section 11.6.5.3**

13. The Project onshore electrical infrastructure falls within the Isle of Anglesey County Council local authority boundaries. **Table 11-5** provides details of the local planning policy documents and the relevant policies in respect of marine ornithology.

Table 11-5 Joint Local Development Plan (Anglesey and Gwynedd) Relevant Policy and Guidance Requirements

Policy/Guidance	Policy/Guidance Purpose
Policy ISA 4: Safeguarding Existing Open Space	To protect open spaces as an invaluable amenity resource
Policy AND 3: Other Renewable Energy and Low Carbon Technologies	Proposals for renewable and low carbon energy technologies, other than wind or solar, which contribute a low carbon future will be permitted, provided that the proposal conforms to the following criteria… "All impacts on landscape character, heritage assets and natural resources have been adequately mitigated, ensuring that the special qualities of all locally, nationally and internationally important landscape, biodiversity and heritage designations, including, where appropriate, their settings are conserved or enhanced".
Strategic Policy PS 19: Conserving and where appropriate enhancing the Natural Environment	The Councils will manage development so as to conserve and where appropriate enhance the Plan area's distinctive natural environment, countryside and coastline, and proposals that have a significant adverse effect on them will be refused unless the need for and benefits of the development in that location clearly outweighs the value of the site or area and national policy protection for that site and area in question. When determining a planning application, consideration will need to be given to the following: 1. Safeguard the Plan area's habitats and species, geology, history, the coastline and landscapes; 2. Protect or where appropriate enhance sites of international, national, regional and local importance and, where appropriate, their settings in line with National Policy; 3. Have appropriate regard to the relative significance of international, national or local designations in considering the weight to be attached to acknowledged interests, ensuring that any international or national responsibilities and obligations are fully met in accordance with National Policy; 4. Protect or enhance biodiversity within the Plan area and enhance and/or restore networks of natural habitats in accordance with the Local Biodiversity Action Plans and Policy AMG 5; 5. Protect or enhance biodiversity through networks of green/ blue infrastructure; 6. Safeguard internationally, nationally and locally protected species; 7. Protect, retain or enhance the local character and distinctiveness of the individual Landscape Character Areas (in line with Policy AMG 2) and Seascape Character Areas (in line with Policy AMG 4); 8. Protect, retain or enhance trees, hedgerows or woodland of visual, ecological, historic cultural or amenity value
Policy AMG 4: Coastal Protection	In considering a proposal on the coast, including the Heritage Coast, there will be a need to ensure that the proposal conforms to the following criteria:-… It does not cause unacceptable harm to:.. "the area's biodiversity interests (including European Protected Areas such as marine Special Areas of Conservation and Special Protected Areas) due to their location, scale, form, appearance, materials, noise, or emissions or due to an unacceptable increase in traffic…"
Policy AMG 5: Local Biodiversity Conservation	Proposals must protect and, where appropriate, enhance biodiversity that has been identified as being important to the local area by:

Policy/Guidance	Policy/Guidance Purpose
	Avoiding significant harmful impacts through the sensitive location of development. . Considering opportunities to create, improve and manage wildlife habitats and natural landscape including wildlife corridors, stepping stones, trees, hedges, woodlands and watercourses. A proposal affecting sites of local biodiversity importance will be refused unless they can conform with all of the following criteria:- ▪ That there are no other satisfactory alternative sites available for the development. ▪ The need for the development outweighs the importance of the site for local nature conservation; ▪ That appropriate mitigation or compensation measures are included as part of the proposal. Where necessary, an Ecological Assessment which highlights the relevant local biodiversity issues should be included with the planning application.
Policy AMG 6: Protecting Sites of Regional or Local Significance	Proposals that are likely to cause direct or indirect significant harm to Local Nature Reserves (LNR), Wildlife Sites (WS) or regionally important geological / geomorphologic sites (RIGS) will be refused, unless it can be proven that there is an overriding social, environmental and/or economic need for the development, and that there is no other suitable site that would avoid having a detrimental impact on sites of local nature conservation value or local geological importance. When a development is granted, it will be necessary to ensure that there are appropriate mitigation measures in place. It will be possible to use planning conditions and/or obligations in order to safeguard the site’s biodiversity and geological importance.

11.3. CONSULTATION

14. An extensive consultation process has occurred prior to and during the preparation of this chapter. This is summarised in **Table 11-6**, with greater detail provided in **Table 11-7**.

Table 11-6 Summary of Consultation Responses

Consultee	Date	Document/Meeting	Agenda/Comments
Natural Resources Wales (NRW) and Sea Mammal Research Unit (SMRU)	16/06/2016	Project overview and PDE	Advice fed into production of 2017 scoping report
RSPB (Royal Society for the Protection of Birds)	17/06/2016	Project overview and PDE	Advice fed into production of 2017 scoping report
NRW	02/08/2016	Seabird and marine mammal survey scope	Advice letter fed into development of survey scopes for seabirds and marine mammals
NRW	24/05/2017	Project update and proposed new consenting route	Project update, summary of survey work undertaken to date, no substantive feedback

Consultee	Date	Document/Meeting	Agenda/Comments
RSPB	26/05/2017	Project update and proposed new consenting route	Project update, summary of survey work undertaken to date, no substantive feedback
Isle of Anglesey County Council (IoACC)	14/06/2017	Scoping Opinion	Advice fed into EIA process
Welsh Government (WG)/NRW	11/07/2018	Scoping Opinion	Advice fed into EIA process
NRW	29/09/2017	Update on progress with bird surveys, discussion regarding further survey effort	Feedback built into the EIA approach for **Chapter 11, Marine Ornithology**.
RSPB	13/12/2017	Update on progress with bird surveys	Feedback built into the EIA approach for **Chapter 11, Marine Ornithology**.
RSPB	24/01/2018	Project update	Project update, no substantive feedback

NRW	13/12/2018	TWG First Meeting	Assessment Approach
			▪ Project background (recap)
			▪ Review of project design envelope
			▪ Species, conservation sites and populations to be included
			▪ Appropriate spatial scale for assessment
			▪ Review species parameters and vulnerability by species/group:
			  ▪ Above water
			  ▪ Submerged
			  ▪ Foraging distances
			▪ Approach to CRM/ERM
			  ▪ Appropriate avoidance rates
			▪ Potential Biological Removal
			▪ Approach to assessment / potential impacts
			▪ Cumulative assessment
			▪ Summary

NRW	19/02/2019	TWG Second Meeting	Assessment Parameters ▪ Overview of Collision Risk Modelling (CRM) and Encounter Rate Modelling (ERM): ▪ Methods, limitations, interpretation, role in EIA ▪ Device parameters and overview of modelling scenarios ▪ Bird input parameters (densities and diving behaviour) and sources of information ▪ Avoidance rates

Consultee	Date	Document/Meeting	Agenda/Comments
			▪ Presentation and review of preliminary results ▪ Plans for future work ▪ Obtaining feedback on work already undertaken and planned
RSPB	17/04/2019	RSPB Project update	Key EIA elements presented: ▪ Key species distribution predicted based on baseline surveys and other existing data ▪ Disturbance at breeding sites ▪ Collision – models, parameters, avoidance rates, data sources – No outputs as yet ▪ Population Viability Analysis (PVA) – No outputs as yet ▪ Habitats Regulations Assessment screening – preliminary outcomes only ▪ Terrestrial Ornithology EIA Key points ▪ Chough distribution ▪ Disturbance at breeding sites ▪ HRA screening – preliminary outputs Key marine ornithology impacts covered in call: ▪ Airborne noise and visual disturbance ▪ Disturbance at breeding sites ▪ Collison risk
NRW	03/05/2019	TWG Third Meeting	Updated on: ▪ Device parameters and grouping ▪ ERM/CRM ▪ Apportioning ▪ Non-breeding season guillemot data ▪ Uncertainty around diving behaviour ▪ PVA for razorbill and guillemot ▪ EIA approach update ▪ Airborne noise and visual disturbance ▪ Monitoring approach ▪ HRA ▪ Terrestrial ornithology
RSPB	31/05/2019	RSPB Project update	Issues discussed included: ▪ Deployment strategy ▪ EIA overview ▪ Airborne noise and visual disturbance ▪ Collision risk ▪ PVA ▪ Monitoring post consent

Consultee	Date	Document/Meeting	Agenda/Comments
			▪ HRA ▪ Onshore ornithology ▪ Seascape, Landscape and Visual Impact Assessment (SLVIA)

Table 11-7 Detailed Consultation Responses

Consultee	Date/Document	Comment	Response
NRW	First TWG Meeting December 2018	NRW agrees in principle with the list of species to be included in the assessment, but we would need to see the raw data from the two years' worth of survey undertaken.	Whilst not part of this chapter, this has been issued to NRW for review and included in processed form within **Appendices 11.1 and 11.2** (**Volume III**).
NRW	First TWG Meeting December 2018	We advise that the applicant could also use Wildfowl and Wetlands Trust (WWT) & European Seabirds At Sea (ESAS) combined data set, Future of the Atlantic Marine Environment (FAME), Biologically Defined Minimum Population Scales (BDMPS) and there will be various other papers and data sources available that show the movement of birds from sites.	The full list of data sources used during the assessment is presented in **Section 11.4**.
NRW	First TWG Meeting December 2018	The applicant needs to consider not just HRA issues bit also EIA issues which will include SSSIs and which features are potentially affected	SSSIs are explicitly referred to in **Sections 11.2** and **11.4.4** and where appropriate, care has been taken to appropriately classify the value of such receptors according to this comment.
NRW	First TWG Meeting December 2018	The list of potential impacts seems comprehensive although the potential impact of lighting on seabirds is missing. We recommend that this potential impact is included for assessment.	This has been considered in impact assessments for construction, operation / repowering and decommissioning in **Section 11.6**.
NRW	First TWG Meeting December 2018	Here the applicant produces definitions for magnitude of effect. These may well not be applicable to sites, with magnitude of effect on an SPA being assessed by looking at the conservation objectives and SSSIs being looked at by levels of population for that SSSI. Also, the magnitude of change could well depend on the rarity of the population, in terms of its status in the UK, Europe or world.	The assignment of values of receptors in **Table 11-8** and **Table 11-10** has taken this comment into account.

Consultee	Date/Document	Comment	Response
NRW	First TWG Meeting December 2018	We believe that the mean- maximum distances provided in Thaxter *et al.* (2012) should be used as a coarse screening filter for sites in the breeding season and that data from papers and FAME/STAR should then be used to provide a more detailed look at where the birds come from. Furness (2015) should be used where applicable to try and allocate birds in non-breeding months.	This approach has been used where more recent information was not available. See **Table 11-11**
NRW	First TWG Meeting December 2018	NRW believes that both the Encounter Rate Model (ERM) and the Collison Risk Model (CRM) should be used, similar to the approach being taken for the marine mammal work.	Noted, both models have been utilised within the assessment. These impacts are assessed in **Section 11.6.6.3** and further detail on the methodology is outlined in **Appendix 11.3** (**Volume III**).
NRW	First TWG Meeting December 2018	NRW does not agree with the different groupings and would like to see more groups which may well have a similarity in the collision risk models. For instance, floating devices may have more contact with diving birds as closer to the surface. NRW feels that the groupings need further consideration.	Noted, the categorisation of devices has been updated and is shown in full in **Chapter 4, Project Description**.
NRW	Second TWG Meeting February 2019	The SNH guidance, Page 3; 2.1 Encounter Rate Model; "states that the resulting encounter rate is expressed in terms of number of animals per month or year which would encounter a turbine." Therefore, month should be used.	Both ERM and CRM calculate a number of collisions per second, which can be multiplied up to any time period that requires assessment. To maximise ecological relevance, collision rates are presented for breeding and non-breeding seasons rather than by month.
NRW	Second TWG Meeting February 2019	As stated in the SNH guidance document (2016); page 14, a range of avoidance rates should be applied to the results of both ERM and CRM to generate a range of estimates of potential collision rates. These are advised to be avoidance rates 0 %, 50 %, 90 %, 95 %, 98 % and 99 %.	Noted, the results of the ERM and CRM have been presented against this range of avoidance rates, with a further two added. (see **Section 11.6.6.3**)
NRW	Second TWG Meeting February 2019	Where there isn't adequate data it is ok to use the correction factors in Stone *et al*. (1995)	Noted, Stone et al. (1995) have been used to correct on-sea species densities where relevant, as outlined in **Appendix 11.2** (**Volume III**).

Consultee	Date/Document	Comment	Response
NRW	Second TWG Meeting February 2019	However, we would like to see information concerning the model selection and also, as stated above, the applicant needs to consider and show how availability bias and watch time has been used.	Noted, information on the methodology is presented in **Appendix 11.3** (**Volume III**).
NRW	Second TWG Meeting February 2019	Could the Guillemot and Razorbill be divided out before the distance analysis and then the correction factors for the area be used? This work should then be worked up into monthly/seasonal population estimates, for the entire development zone plus the buffer explaining how this was extrapolated from the densities and look at how the heterogeneity in densities may affect the estimate.	Area-specific correction factors have been used to generate densities for the entire development zone and 2 km buffer by relevant biological season for guillemot, razorbill and herring gull. These are presented in **Appendix 11.2** (V**olume III**), along with confidence intervals. Other species were not recorded sufficiently frequently during surveys to enable this to occur, so generic correction factors have been used instead.
NRW	Second TWG Meeting February 2019	As stated previously, the applicant has left out a number of significantly large colonies for various species including some SSSIs. They will not be able to allocate birds to colonies until they have done a thorough review of this looking at the up to date data on the Seabird Monitoring Programme (SMP).	This comment has been addressed; see apportioning in **Table 11-11**.
NRW	Second TWG Meeting February 2019	This vulnerability for Manx shearwater was worked out before Shoji's paper showed that Manx shearwaters do dive to greater depths than thought previously and therefore it should be considered to have a higher sensitivity than "Low".	Manx shearwaters have been classified as having medium sensitivity with respect to collision risk (**Section 11.6.6.3.2**).
NRW	Second TWG Meeting February 2019	In terms of the CRM and ERM is the applicant looking at the density of gannets from flight (as gannets most often dive from flight for food) or from birds on the water, or a mixture of both?	Flying densities have been used for ERM/CRM for gannet.
NRW	Third TWG Meeting May 2019	NRW advise that the applicant needs to look not just at Minesto but all other plans or projects that could have an additive effect on a site.	All appropriate plans and projects have been included in **Section 11.6.8**.
NRW	Third TWG Meeting May 2019	Avoidance rates will be presented using the range outlined in SNH (2016).	Noted, the results of the ERM and CRM have been presented against this range of avoidance

Consultee	Date/Document	Comment	Response
		Outcomes of PVA indicate that avoidance of 99% and higher will be important based upon PVA for guillemot and razorbill. For other species lower values are indicated.	rates (see **Section 11.6.6.3**). PVA is included in **Appendix 11.3** (**Volume III**).
NRW	Third TWG Meeting May 2019	NRW requested that all sites should be screened in initially and taken through to AA.	The HRA is presented in **Document MOR/RHDHV/DOC/0067** (**Information to Support HRA**).
NRW	Third TWG Meeting May 2019	NRW raised the potential for active sonar to be used and advise that the applicant needs to consider whether other monitoring could also be available to be used.	A deployment and monitoring strategy will be produced for consultation with the SNCBs.
NRW	Third TWG Meeting May 2019	RHDHV confirmed that an AA will be carried out for chough.	The HRA is presented in **Document MOR/RHDHV/DOC/0067** (**Information to Support HRA**).
Planning Inspectorate	Scoping Report 2018	In accordance with Rule 16 of the EIA Regulations, the ES should provide a description of the likely significant transboundary effects, where relevant.	This is included within **Section 11.7**.
Planning Inspectorate	Scoping Report 2018	It is recommended that the Applicant makes efforts to agree the relevant study areas with NRW and that they are appropriate to ensure any likely significant effects are identified in the ES.	These have been agreed with NRW throughout the TWG meetings.
Planning Inspectorate	Scoping Report 2018	There are number of errors in the Table 8-1 including incorrectly named designated sites and features. The Applicant should ensure that any such errors are omitted from information in the ES. There are a greater number of designated sites listed in Table 8-1 of the Scoping Report than shown on Figure 8-1. The ES should include figures identifying the location of all designated sites discussed in the text and also identify the distance of the designated sites from the Proposed Works	This has been incorporated into this chapter and the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
Planning Inspectorate	Scoping Report 2018	The potential impacts are duplicated in Table 8-2, although do not always correlate with the potential impacts identified in Table 8-1 (e.g. effects of lighting are noted in Table 8-1 but not Table 8-2). Where relevant the Applicant should ensure consistency between information presented in the ES.	The full list of potential impacts for marine ornithology are presented in **Section 11.6.2**.

Consultee	Date/Document	Comment	Response
Planning Inspectorate	Scoping Report 2018	The ES should provide details of any models used, the input parameters and any assumptions made in the models. Any guidance used to inform the assessment should be detailed within the ES.	A detailed assessment methodology has been presented.
Planning Inspectorate	Scoping Report 2018	Cumulative impacts should be assessed for all aspect chapters where significant effects are likely to occur.	Cumulative impacts for marine ornithology are presented in **Section 11.6.8**.
Planning Inspectorate	Scoping Report 2018	It is recommended that the other projects to be included within the cumulative assessment are discussed, and ideally agreed, with relevant consultees.	The list of projects included within the CIA are available within **Section 11.6.8**.
Planning Inspectorate	Scoping Report 2018	Although produced for Nationally Significant Infrastructure Projects, the Applicant is advised to utilise the approach set out in Planning Inspectorate Advice Note Seventeen: Cumulative effects assessment.	The methodology for CIA in terms of marine ornithology receptors is presented in **Section 11.6.8**.
NRW (for PINS)	Scoping Report 2018	It is important that there is distinction between the EIA and HRA processes; however, the information contained within the ES may be of relevance and may be used within the HRA. We therefore recommend that the ES should include a section containing 'information to inform the HRA'.	This comment has been noted. However, as HRA and EIA issues are distinctly different for the Project, no such section has been incorporated into the ES chapter or wider ES.
NRW (for PINS)	Scoping Report 2018	Without wishing to prejudice the HRA or consenting process, a package of measures that would avoid or mitigate the effects of the proposal and avoid adverse effects on the integrity of European protected sites would appear challenging to achieve in this instance. If this is the case it may be necessary to consider the proposal under Regulation 64 of the above regulations, where the possibility of alternatives to the proposal that would not give rise to adverse effects on the integrity of European protected sites are considered.	The HRA demonstrates that no adverse effect on the integrity of the relevant designated sites is predicted (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**)
NRW (for PINS)	Scoping Report 2018	In our previous EIA scoping responses to Anglesey County Council and NRW's Marine Licensing Team we stated that we agreed with the designated sites, species and receptors identified within section 7 of the scoping report (table 8.1 in current EIA scoping report) to be included within the EIA and HRA. We noted that the Anglesey Terns SPA was not included within the scoping report and	Noted, these errors have been corrected and Anglesey Tern SPA has been assessed in detail within the HRA process (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**). The qualifying species of this SPA are of low sensitivity to the

Consultee	Date/Document	Comment	Response
		should be considered as part of any subsequent ES. Table 8.1 has since been changed and now contains numerous errors. We strongly advise that these are rectified prior to the submission of any ES.	Project, though are considered within the EIA.
NRW (for PINS)	Scoping Report 2018	A number of the designated sites included in table 8.1 (and throughout the report) are incorrectly named and there are several examples of duplication, possibly stemming from the fact that some sites have both a Welsh and an English name. Where sites are duplicated, such as is the case for Llyn Dinam SAC, Glannau Ynys Gybi/Holy Island Coast SPA, Glannau Rhoscolyn/Rhoscolyn Coast SSSI and Porth Diana SSSI to name a few, differing (conflicting) levels of potential impacts are often reported.	These errors have been corrected.
NRW (for PINS)	Scoping Report 2018	The 'features' column text for the Anglesey Terns SPA in table 8.1 suggests a single island colony, however, please note that the site comprises 3 separate breeding colonies and extensive areas of surrounding sea. The numbers of breeding pairs provided for the site should be checked for accuracy.	This detail is included within the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW (for PINS)	Scoping Report 2018	The new power station at Wylfa is mentioned in relation to potential onshore cumulative impacts (see section 10.1.2). We advise that offshore aspects of the power station also need to be considered, including HNP's plans for sediment and rock disposal at Holyhead Deep (this is in addition to the existing use of the disposal ground from Holyhead Port), increased boat traffic / shipping movements and biosecurity. It should also be noted that the HNP Wylfa Newydd development will mostly sit adjacent to the existing power plant rather than use the same site footprint.	Noted, however, due to the suspension of the Wylfa Newydd project, this has not been considered within the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**). Should further updates become available, this will be revisited.
NRW (for PINS)	Scoping Report 2018	It's important to note that, in addition to inter-project effects outlined in Section 10, intra-development effects, where multiple development elements have the potential to impact the same receptor, need to be considered throughout the relevant ES chapters and wider EIA process.	Noted, such effects on marine ornithology have been considered in **Section 11.8**.
IACC 2017	Scoping Report 2018	The list of projects to be assessed in terms of cumulative and in-	Noted, the list of projects to be considered for

Consultee	Date/Document	Comment	Response
		combination impacts appears limited. The EIA should consider an agreed list of proposals at an agreed cut-off date before submission of the planning application.	ornithology for CIA are presented in **Section 11.6.8**, and an in-combination assessment has been completed as part of the HRA process (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
IACC 2017_Revised Scheme	Scoping Report 2018	The proposed development is intended to be located in a sensitive area from the perspective of landscape and biodiversity with a number of European and nationally delegated areas either covering or adjacent to the application site. The whole of the application site is contained within the North Anglesey Marine SAC and Anglesey Terns SPA with the landfall site contained within the Holy Island SSSI. As such, any development proposed in this area must have regard to the sensitive environment and must therefore provide sufficient mitigation where impacts are identified.	The impacts of the Project on these designated sites is presented within this chapter and the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW	Scoping Report 2018	Guidance provided to the applicant by NRW Technical Experts (TE) to assist with scoping the proposal and EIA does not appear to have been fully used to inform all aspects of the EIA scoping report. We also note that the scoping report has not drawn upon information collated within the Crown Estate’s plan level Habitats Regulation Appraisal for their 2013/14 wave and tidal leasing round. NRW TE has previously provided a guidance note to you on how we considered that this information could be used at an individual demonstration zone level.	Updated guidance provided within the TWG meetings has been used to inform this chapter of the ES. The HRA takes into consideration the plan level HRA compiled on behalf of the Crown Estate (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW	Scoping Report 2018	We draw your attention to the requirement of Article 6 of Schedule 3 of the MWR which requires you to consider the potential transboundary effects of the project.	Noted, these effects have been considered within **Section 11.7**.
NRW	Scoping Report 2018	In Table 8.2 the potential for underwater noise to directly disturb seabird and diving bird interest features should be assessed in the ES.	Noted, this is not expected to be a critical impact, but is covered within **Section 11.6**.

Consultee	Date/Document	Comment	Response
NRW	Scoping Report 2018	The cumulative assessment should include other proposed and existing Marine Licence applications such as disposal at Holyhead North disposal site. Information on marine licence applications can be found on the Welsh Government Marine Planning Portal or downloaded from Lle. The assessment should also include developments allocated within the statutory development plan, proposals in the ANOB management plan and in the draft Wales National Marine Plan (each of which is supported by an Environmental Report and Habitats Regulations Assessment). Regard should also be given to Natural Resources Wales' emerging Area Statements (Marine and North-West Wales Areas), when published.	Noted, a list of all projects and planned considered within the CIA for marine ornithology is included in **Section 11.6.8**.
NRW	Scoping Report 2018	The consideration of underwater noise cumulative effects should include activities in the wider area, such as navigation and fishing, as well as any other project developments.	Underwater noise from the Project alone was assessed to have negligible impact significance, and was therefore screened out of CIA.
NRW	Scoping Report 2018	It should be noted that the Habitats Regulations Assessment for the Draft Welsh National Marine Plan, which was published in December 2017, was unable to rule out Adverse Effect on Integrity for multiple SPA, SAC and Ramsar sites and features. These conclusions should be taken into account when screening relevant plans or projects under the Habitats Regulations that could have an in-combination effect on those sites and when considering cumulative and synergistic effects under the Environmental Impact Assessment and Strategic Environmental Assessment Regulations.	This has been taken into account during the preparation of the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
Planning Inspectorate	Scoping Report 2018	The ES should detail the foraging distances used for migratory species, along with references to justify the distances used.	A range of literature has been utilised for the purpose of identifying the likely origin of birds recorded during baseline surveys (**Table 11-11**)

Consultee	Date/Document	Comment	Response
Planning Inspectorate	Scoping Report 2018	Displacement from vicinity of turbine: Table 8-9 of the Scoping Report states that displacement is expected to be both minor and localised, however the report also acknowledges a "lack of understanding on whether operation / repowering of devices cause displacement". The ES should therefore provide further justification to support the conclusions reached. If necessary, further assessment should be undertaken to ensure the validity of the findings. The potential indirect effects from displacement should also be assessed in the ES e.g. energy expenditure from species avoiding the area.	Displacement due to tidal devices is considered in detail in relation to available evidence, and is expected to be minimal (**Section 11.6.6.1**)
Planning Inspectorate	Scoping Report 2018	Statements such as "these species are relatively tolerant of vessel activity" should be corroborated by relevant evidence.	Evidence is provided throughout **Section 11.6**.
Planning Inspectorate	Scoping Response 2018	The ES should consider and assess any potentially significant indirect effects on ornithological receptors, including those resulting from impacts to prey species.	This is covered for construction, operational / repowering and decommissioning Project phases within **Section 11.6**
NRW (for PINS)	Scoping Response 2018	We recommend that the applicant first reviews available baseline data to ascertain which species have been found within the areas of sea/coastal areas potentially affected. For the offshore areas this may include ESAS data (ESAS/WWT in the past).	A full list of the baseline information utilised to inform the assessment of the Project on marine ornithology is presented in **Section 11.5.**
NRW (for PINS)	Scoping Response 2018	We advise that the mean maximum foraging ranges detailed within Thaxter et al (2012) are utilised to determine which breeding colonies could be affected by the proposed development, with particular emphasis on colonies that are features of SPAs and SSSIs. There is no mention of Skomer and Skokholm SPA and the Glannau Aberdaron and Ynys Enlli / Aberdaron Coast and Bardsey Island SPA, for example, designated for Manx shearwater. We would welcome a map which shows the seabird features of designated sites within mean maximum foraging range of the proposed demonstration zone.	This reference has been used, along with others, in assessing the potential origin of marine ornithology receptors (**Table 11-11**).
NRW (for PINS)	Scoping Response 2018	The ES should consider the potential for displacement of food sources from the area in addition to displacement of birds themselves; to date the EIA	This is covered for construction, operational / repowering and decommissioning Project

Consultee	Date/Document	Comment	Response
		scoping report has not addressed this point.	phases within **Section 11.6**.
RSPB	Scoping Response 2018	We note the reference to Thaxter *et al* (2012) who initially set the standard of mean-maximum foraging ranges based on seabird tracking data. However, updated foraging distances are now available and greater than those used by Thaxter. These derive from the Future of the Atlantic Marine Environment (FAME) and Seabird Tracking and Research (STAR) projects. We recommend that reference be made to the FAME/STAR data	This reference has been used, along with others, in assessing the potential origin of marine ornithology receptors (**Table 11-11**).
RSPB	Scoping Response 2018	We understand the on-going offshore ornithological surveys follow an adapted ESAS methodology for tidal development sites. It would be helpful to get confirmation of the distance sampling correction method to deal with reduced visibility of diving birds further from the boat transects. In particular, if there is the intention to use program Distance (or similar) to correct the estimates of density of birds on the water. There is potential to supplement the above information with the use of GPS tags, applied to target species. This technology which has been trialled at a number of seabird colonies in the UK can incorporate remote download systems and thus remove the need to recapture birds.	Full details of the baseline data collection is presented in **Appendix 11.1** (**Volume III**). Distance sampling was carried out using program Distance 7.2. GPS tagging data was not used during baseline data collection. However, tracking data and associated publications have been used in the assessment where relevant.
RSPB	Scoping Response 2018	The potential impact of collision risk between diving birds and moving parts of devices is mentioned in the document. We consider that this operational risk needs further consideration through robust collision risk modelling. Guidance is available from SNH and we would recommend that further advice be sought from NRW on this matter.	ERM and CRM have been used within the assessment, as detailed in **Section 11.6.6.3** and **Appendix 11.3** (**Volume III**).

Consultee	Date/Document	Comment	Response
RSPB	Scoping Response 2018	The scope of the Cumulative Impact Assessment is project focused, although the temporal or 'time frame' boundary is not clearly defined. We recommend the scoping should include developments allocated within the statutory development plan, proposals in the ANOB management plan and in the draft Wales National Marine Plan (each of which is supported by an Environmental Report and Habitats Regulations Assessment). Regard should also be had to Natural Resources Wales' emerging Area Statements (Marine and North-West Wales Areas).	The full list of projects considered within the CIA for marine ornithology are presented in **Section 11.6.8.**
NRW	Scoping Response 2018	There is no mention in the scoping report of potential disturbance and displacement effects of underwater noise on seabird and diving bird species as a result of the project.	Noted. This is not expected to be a critical impact but is covered within **Section 11.6** for marine ornithology and **Chapter 12, Marine Mammals**.
IoACC	Scoping Response 2017	Anglesey Terns SPA was not included in the Scoping Report and should be considered as part of subsequent planning application, along with other identified sites	Anglesey Terns SPA has been considered within the HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**), and the qualifying features are considered within the EIA as appropriate.
IoACC	Scoping Response 2017	Consider impact on protected species and demonstrate will not impact on Favourable Conservation Status of European and Nationally protected species Propose and deliver appropriate mitigation /compensation schemes to ensure favourable conservation status.	The HRA demonstrates that no adverse effect on the integrity of the relevant designated sites is predicted (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**)
NRW	Scoping Response 2015	Proposed developments likely to significantly affect European Sites (Special Areas of Conservation (SACs), Special Protection Areas (SPAs), either alone or in combination with other plans or Projects, require special consideration by the Competent Authority (typically the licensing authority) under Regulation 61 of the Habitats Regulations. As a matter of Government policy, the same applies to Ramsar sites.	The HRA demonstrates that no adverse effect on the integrity of the relevant designated sites is predicted (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).

Consultee	Date/Document	Comment	Response
NRW	Scoping Response 2015	The HRA is a two stage process, the first stage being a 'Test of Likely Significant Effect' to establish whether the proposals are likely to result in significant effects on any European sites (and Ramsar sites). If this establishes that significant effects are likely, or there is uncertainty whether significant effects are likely to result, then an appropriate assessment of the effects of the activity in view of the conservation objectives of the site(s) is required. The HRA also needs to consider in-combination effects of the proposed Project with other projects.	For full details of the HRA Screening and Appropriate Assessment, where relevant, see the Project HRA (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW	Scoping Response 2015	It is difficult to determine from the information provided in the scoping report the potential impacts and the significance of potential impacts, for protected sites. The EIA should concentrate on impacts both direct and indirect on marine and coastal sites and those adjacent to the cable route and any land-based infrastructure.	The full list of potential impacts on marine ornithology are presented in **Section 11.6.2**.
NRW	Scoping Response 2015	The scoping report appears to have gone beyond the stated 50km area of search by including seabird SPAs as far as Pembrokeshire. We agree that these SPAs should be included as they are within the mean maximum foraging range of some of the classified features, especially gannet (640km) and Manx shearwater (400km).	The full list of the potential origin of marine ornithology receptors is presented in **Table 11-11**, and the European sites included in the HRA is presented in that document (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW	Scoping Response 2015	Within Table 7.1 Habitats Directive sites in Ireland and also in other areas around the Irish Sea are not mentioned in the table. In view of the international nature of the Habitats Directive, designated sites in other countries should also be considered.	The full list of the potential origin of marine ornithology receptors is presented in **Table 11-11**, which includes SPAs from the Republic of Ireland. The list of European sites included in the HRA is presented in that document (**Document MOR/RHDHV/DOC/0067, Information to Support HRA**).
NRW	Scoping Response 2015	The largest guillemot colony in North Wales, namely Carreg y Llam SSSI has been omitted from the list of protected sites. This SSSI with its notified feature of breeding guillemot should be added for consideration.	This site has not been included in the baseline environment, because the latest information on the at-sea distribution of guillemots and razorbills

Consultee	Date/Document	Comment	Response
			(Cleasby *et al*., 2018) indicates that 100 % of birds at the site of the Project originate from the South Stack and Penlas Seabird Monitoring Programme Master Site sub-colonies.
NRW	Scoping Response 2015	The EIA should include assessment of the potential for birds to collide with structures that are lit at night	Noted, this is not expected to be a critical impact, but is covered within **Section 11.6.5.1.3**.
NRW	Scoping Response 2015	We consider that the use of boat-based surveys would enable true densities of seabirds to be ascertained to enable accurate predictions of impact to satisfy the requirements of both EIA and HRA.	Boat-based surveys were carried out monthly for two years, as detailed in **Appendix 11.1** (**Volume III**).
NRW	Scoping Response 2015	In the first row of Potential Impacts Table 7.8, we consider that there is also potential for birds to impact structures in normal flight at night or (especially) in strong winds/ storms. This potential impact should be included in the EA.	This impact pathway has not been screened into the EIA as there is no evidence that suggests marine ornithology receptors would be susceptible to collisions in flight with the surface elements of tidal device.
NRW	Scoping Response 2015	Key areas of concern for ornithology which must be assessed in the EIA include: ▪ Collision risk ▪ Disturbance/Habitat Exclusion/Displacement ▪ Sedimentary Processes and Pollution ▪ Indirect impacts (i.e. to birds, fish and marine mammals due to habitat loss for prey, depletion, displacement or aggregation of prey)	A full list of the potential impacts considered for marine ornithology is presented in **Section 11.6**, and includes all these areas of concern.
NRW	Scoping Response 2015	RSPB research into potential effects of wave and tidal stream devices on birds recommends that, due to the paucity of systematic data, the longevity of birds, inter-annual and weather dependant variations, at least two years of pre-application data are collected, covering all seasons and including both breeding and non-breeding populations.	Boat-based surveys were carried out monthly for a two year period, as detailed in **Appendix 11.1** (**Volume III**).

Consultee	Date/Document	Comment	Response
NRW	Scoping Response 2015	We recommend early engagement with all of those organisations with an interest in ornithology to gain advice on survey methods.	Details of consultation undertaken is presented in this section of the chapter.
NRW	Scoping Response 2015	There is potential not only to mitigate for the adverse impacts of the development, but also to enhance the biodiversity of the development site and its vicinity. This should be addressed in the ES. Mitigation/enhancement measures if required could include: ▪ Time-related restrictions on construction, in relation to nesting periods. ▪ The use of sympathetic land management	Where required, mitigation is presented in **Section 11.6**.

11.4. METHODOLOGY

11.4.1. Study Area

15. The study area for the boat-based bird surveys (**Section 11.4.3**), was the Morlais Demonstration Zone (MDZ) plus a 2 km buffer, including the Export Cable Corridor (ECC) (**Appendix 11.1, Volume III**). This reflects the fact that most effects that occur during the construction, operation / repowering and decommissioning of the Project will be localised in nature, with the ZoI of the majority of effects predicted to occur within the MDZ and ECC.

16. For breeding seabirds, mean maximum foraging ranges (Thaxter et al., 2012) were used to identify the colonies that birds recorded within the MDZ and 2 km buffer during the boat-based bird surveys could have originated from. For birds recorded outside their respective breeding seasons (**Table 11-9**), when many species of seabird disperse and/or migrate from their breeding colonies, Furness (2015) was used to identify the populations from which individuals recorded during surveys at this time of year originated.

11.4.2. Data Sources – Desk Study

17. A desk study has drawn on both peer reviewed scientific literature and “grey literature” such as project submissions and reports. It includes information on seabird ecology and distribution, and the potential impacts of tidal stream development on marine ornithology. The key topics for which the literature has been examined include (but are not limited to):

- Bird population estimates (Banks et al., 2007; Frost et al., 2018; Furness, 2015; Musgrove et al., 2011; NRW, 2015a; O’Brien et al., 2010; Perrins et al., 2012; Stroud et al., 2016; Wernham et al., 2002);
- Bird ecology (Coulson, 2011; Cramp, 1985; Cramp and Simmons, 1983, 1977; Dean, 2012; Furness et al., 2018; Harris and Wanless, 2011; Robinson, 2019; Thaxter et al., 2010);

- Bird distribution, foraging and migration (Cleasby et al., 2018; Clewley et al., 2017; Cox et al., 2016; Dean et al., 2012, 2015; Frederiksen et al., 2012b; Guilford et al., 2008; Hobson and Welch, 1992; Oppel et al., 2018; Perrow et al., 2011; Schwemmer and Garthe, 2008; Shoji et al., 2015; Thaxter et al., 2012; Wakefield et al., 2013, 2017; Wernham et al., 2002; Wilson et al., 2014);
- Bird diving behaviour (including nocturnal activity) (Cox et al., 2016; Garthe et al., 2000; MBIEG, 2019; Regular et al., 2010, 2011; Robbins, 2017; Shoji et al., 2016, 2015; Thaxter et al., 2009); and
- Potential impacts of marine development on birds (APEM, 2017; Dierschke et al., 2016; Furness et al., 2012; Furness and Wade, 2012; Garthe and Hüppop, 2004; Gill et al., 2018; Harwood et al., 2017; Leopold et al., 2013; MMO, 2018; Vallejo et al., 2017; Vanermen et al., 2015).

18. Information on statutory sites and their interest features has been drawn from the web-based resource Multi-Agency Geographic Information for the Countryside (MAGIC).

11.4.3. Data Sources – Site-Specific Surveys and Reports

19. Two years of baseline seabird surveys of the MDZ and 2 km buffer were undertaken between November 2016 and October 2018. This comprised of 24 surveys which provided coverage of all ecological seasons.

20. Surveys were undertaken by means of boat-based visual surveys, using a transect method. Thirteen parallel transects were followed on all surveys. The survey methodology was based on published guidance (Camphuysen et al., 2004).

21. Full details of the survey programme and the data collected are available in **Appendix 11.1** (**Volume III**). Density estimates derived from these surveys that are used in the assessment are available in **Appendix 11.2** (**Volume III**).

11.4.4. Impact Assessment Methodology

22. The generic methodology utilised for impact assessment in this chapter is described in detail in **Chapter 5, EIA Methodology**. Where required, the methodology has been adapted to make it more specific to marine ornithology receptors and aligned with the key guidance document produced for the impact assessment of ecological receptors (CIEEM, 2018).

23. The impact assessment uses the “source-pathway-receptor” model. The model identifies likely environmental impacts resulting from the proposed construction, operation /repowering and decommissioning of the offshore infrastructure associated with the Project. This process provides a transparent impact assessment route between impact sources and potentially sensitive receptors. The parameters of this model are defined as follows:

    - Source – the origin of a potential impact (noting that one source may have several pathways and receptors) e.g. an activity such as cable installation and a resultant effect such as re-suspension of sediments;
    - Pathway – the means by which the effect of the activity could impact a receptor e.g. for the example above, re-suspended sediment could settle and smother the sea bed; and

- Receptor – the element of the receiving environment that is impacted e.g. for the above example, bird prey species living on or in the sea bed are unavailable to foraging birds.

24. The information presented in **Table 11-8** has been used to determine the importance of marine ornithology receptors recorded in the MDZ and 2 km buffer, and where relevant, the breeding colonies or other populations from which these receptors may originate.

Table 11-8 Definitions of Receptor Importance Levels for Marine Ornithology Receptors

Importance Level	Definition
High	A regularly occurring, nationally significant population / number of any internationally or nationally important species Internationally protected species (e.g. listed on Annex I of the Birds Directive) that are listed as a qualifying interest feature of an internationally protected site An internationally designated site (SPA and/or Ramsar site) or candidate site or an area (e.g. pSPA or dSPA)
Medium	Species which are regionally important or internationally rare Species listed on Section 7 List of Species of Principal Importance for Wales Species on Birds of Conservation Concern (BoCC) Red List (Eaton et al., 2015) A nationally designated site (SSSI)
Low	Species which are locally important or nationally rare Species on BoCC Amber List (Eaton et al., 2015) Species that are occasionally recorded within the study area in low numbers compared to other regions
Negligible	Species which are not considered to be particularly important or rare Species that are infrequently recorded within the study area in very low numbers compared to other areas or regions

25. There are no further deviations from the methodology described in **Chapter 5, EIA Methodology**.

11.5. EXISTING ENVIRONMENT

11.5.1. Species Recorded

26. In total, 34 species of bird were recorded within the MDZ and 2 km buffer during the boat-based surveys, of which 16 were seabirds recorded on the sea and in flight. These were Arctic tern *Sterna paradisaea*, Atlantic puffin *Fratercula arctica* (“puffin”), black-headed gull *Chroicocephalus ridibundus*, black-legged kittiwake *Rissa tridactyla* (“kittiwake”), common gull *Larus canus*, common tern *Sterna hirundo*, great black-backed gull *Larus marinus*, common guillemot *Uria aalge* (“guillemot”), herring gull *Larus argentatus*, lesser black-backed gull *Larus fuscus*, Manx shearwater *Puffinus puffinus*, northern fulmar *Fulmarus glacialis* (“fulmar”), northern gannet *Morus bassanus* (“gannet”), razorbill *Alca torda*, red-throated diver *Gavia stellata* and shag *Phalacrocorax aristotelis*. In addition, one seaduck species was recorded on the sea and in flight; eider *Somateria mollissima*.

27. There were a further five species of seabird recorded in flight only. These were cormorant *Phalacrocorax carbo*, Mediterranean gull *Larus melanocephalus*, great skua *Stercorarius skua*, sooty shearwater *Puffinus griseus* and Sandwich tern *Thalasseus sandvicensis*, along with a single species of seaduck; common scoter *Melanitta nigra*.

28. Great skua and sooty shearwater have been scoped out of further assessment. These species were observed on a single survey each across 24 boat-based surveys, and this, along with the fact that these species are not known to breed or winter in the area in which the Project is situated (Stroud et al., 2016), means that they will not be susceptible to impacts during the construction, operation / repowering or decommissioning of the Project.

29. There were a further 11 bird species recorded during the boat-based surveys that were recorded in flight only, irregularly, and are not species that would be routinely expected to utilise the subtidal habitat within the MDZ or 2 km buffer in the course of their normal behaviour. These are seven species of passerine, house martin *Delichon urbicum*, meadow pipit *Anthus pratensis*, pied wagtail *Motacilla alba*, redwing *Turdus iliacus*, starling *Sturnus vulgaris*, swallow *Hirundo rustica* and sand martin *Riparia riparia*, one species of swan, whooper swan *Cygnus cygnus*, one species of raptor, peregrine *Falcus peregrinus* and two species of wader, dunlin *Calidris alpina* and whimbrel *Numenius phaeopus*. All of these species are excluded from further assessment as they are not considered to be sensitive to impacts due to the construction, operation / repowering or decommissioning of the Project.

30. The remaining species (the marine ornithology receptors) will be assessed for impacts due to the construction, operation / repowering and decommissioning of the Project as they are considered to be at potential risk either due to their abundance or potential sensitivity to the predicted impacts.

11.5.2. Marine Ornithology Receptors Breeding and Non-Breeding Seasons

31. Impacts on the marine ornithology receptors have been assessed in relation to relevant biological seasons (Furness, 2015). These include overlapping months in some instances due to variation in the timing of migration for birds which breed at different latitudes (i.e. individuals from breeding sites in the north of the species' range may still be on spring migration when individuals farther south have already commenced breeding). For each species, the assessment of impacts in different seasons used the full "breeding" and "non-breeding" periods listed in **Table 11-9**.

Table 11-9 Definition of the Breeding, Migration and Winter Seasons for Marine Ornithology Receptors included in the EcIA, as per Furness (2015) unless otherwise stated

Species	Breeding	Migration-free breeding	Migration - autumn	Migration-free winter	Migration - spring	Non-breeding
Arctic tern	May-early Aug	June	Jul-early Sept	Oct-Mar	Apr-May	Sept-Apr
Black-headed gull (Cramp and Simmons, 1983)	-	Apr-Aug	-	-	-	Sept-Mar
Common gull (Cramp and Simmons, 1983)	-	Apr-Aug	-	-	-	Sept-Mar
Common scoter (Cramp and Simmons, 1977)	May-Aug	-	-	-	-	Sept-Apr
Common tern	May-Aug	Jun-mid Jul	Late Jul-early Sept	Oct-Mar	Apr-May	Sept-Apr

Species	Breeding	Migration-free breeding	Migration - autumn	Migration-free winter	Migration - spring	Non-breeding
Cormorant	-	Apr-Aug	-	-	-	Sept-Mar
Eider (Cramp and Simmons, 1977)	Apr-Jun	-	-	-	-	Jul-Mar
Fulmar	Jan-Aug	Apr-Aug	Sep-Oct	Nov	Dec-Mar	Sept-Dec
Gannet	Mar-Sept	Apr-Aug	Sept-Nov	-	Dec-Mar	Oct-Feb
Great black-backed gull	Late Mar-Aug	May-Jul	Aug-Nov	Dec	Jan-Apr	Sept-Mar
Guillemot	Mar-Jul	Mar-Jun	Jul-Oct	Nov	Dec-Feb	Aug-Feb
Herring gull	Mar-Aug	May-Jul	Aug-Nov	Dec	Jan-Apr	Sept-Feb
Kittiwake	Mar-Aug	May-Jul	Aug-Dec	-	Jan-Apr	Sept-Feb
Lesser black-backed gull	Apr-Aug	May-Jul	Aug-Oct	Nov-Feb	Mar-Apr	Sept-Mar
Manx shearwater	Apr-Aug	Jun-Jul	Aug-early Oct	Nov-Feb	Late Mar-May	Sept-Mar
Mediterranean gull (assumed as per black-headed gull)	-	Apr-Aug	-	-	-	Sept-Mar
Puffin	Apr-early Aug	May-Jun	Late Jul-Aug	Sept-Feb	Mar-Apr	Mid Aug-Mar
Razorbill	Apr-Jul	Apr-Jun	Aug-Oct	Nov-Dec	Jan-Mar	Aug-Mar
Red-throated diver	Mar-Aug	May-Aug	Sept-Nov	Dec-Jan	Feb-Apr	Sept-Feb
Sandwich tern	Apr-Aug	June	Jul-Sept	Oct-Feb	Mar-May	Sept-Mar
Shag	Feb-Aug	Mar-Jul	Aug-Oct	Nov	Dec-Feb	Sept-Jan

11.5.3. Marine Ornithology Receptors Conservation Status

32. The conservation status of the identified marine ornithology receptors is summarised in **Table 11-10**.

Table 11-10 Conservation Status of Marine Ornithology Receptors Recorded in the MDZ and 2 km Buffer to be Considered by EcIA

	Conservation status				
Species	**Annex 1 (EU Birds Directive)**	**Schedule 1 (Wildlife & Countryside Act)**	**BoCC Amber (Eaton et al. 2015)**	**BoCC Red (Eaton et al. 2015)**	**Section 7 (Environment (Wales) Act)**

11.5.4. Species Densities

33. Species densities and 90 % confidence intervals for breeding and non-breeding seasons (**Table 11-9**) are presented in **Appendix 11.2** (**Volume III**). These were calculated using Distance correction (Buckland et al., 2001) for those species where the numbers of observations made this possible; guillemot, razorbill and herring gull. For species where this was not possible, generic published corrections to account for missed birds were applied (Stone et al., 1995). Any observations made to group level (e.g. auk species for guillemot and razorbill) were proportionally allocated to a species.

11.5.5. Connectivity of Breeding and Wintering Sites to MDZ

34. Sites which may have connectivity to the MDZ and ECC include colonies supporting breeding seabirds and coastal and/or marine bird interests, which are typically overwintering aggregations.

35. For the breeding period (**Table 11-9**), the potential for connectivity to known breeding populations has been considered. Published mean maximum foraging distances (Thaxter et al., 2012) have been used in conjunction with data from the Seabird 2000 and Seabird Monitoring Programme (SMP) databases (JNCC, 2018, 2010) to identify colonies that are within the mean maximum foraging range of the MDZ/ECC. For some species for which hundreds (or more) of small breeding locations within the mean maximum foraging range are known (e.g. herring gull), the search for breeding locations was restricted to the Gwynedd area. Where relevant, other datasets have also been consulted to provide further insight into the distribution of foraging seabirds at sea. In particular, work concerning the at-sea distributions of four species (guillemot, razorbill, kittiwake and shag) (Cleasby et al., 2018; Wakefield et al., 2017) is considered the best available information for these species and is used to assess connectivity in preference to other methods where clear associations to particular colonies were detected in the datasets. Published methodology on apportioning (SNH, 2018) has also been used where appropriate to

estimate the proportions of species recorded in the MDZ likely to originate from particular breeding colonies.

36. **Table 11-11** provides an overview of this information for the marine ornithology receptors. The location of designated sites relative to the MDZ is shown on **Figure 11-1** (**Volume II**).

Table 11-11 Marine Ornithology Receptors and their Possible Origin

Species	Breeding (B) or Non-breeding (NB)	Site of Origin	Approximate % of MDZ population from site	Justification
Arctic tern	B	Anglesey Terns SPA	100	(JNCC, 2018, 2010; Thaxter et al., 2012)
Black-headed gull	B/NB	Non-designated local population	100	-

11.5.6. Anticipated Trends in Baseline Condition

37. The two key drivers of seabird population size and trends in western Europe are climate change (Burthe et al., 2014; Frederiksen et al., 2012a, 2004; JNCC, 2016; Sandvik et al., 2012, 2005), and fisheries activities (Carroll et al., 2017; Foster et al., 2017; Frederiksen et al., 2004;

Sydeman et al., 2017; Tasker et al., 2000). Pollutants including oil, persistent organic pollutants, plastics, alien mammal predators at colonies, disease, and loss of nesting habitat also affect seabird populations, but are generally much less important and often more local factors (JNCC, 2016; Votier et al., 2008, 2005).

38. Trends in breeding seabird populations and colonies are generally better known and understood than trends in numbers and distribution at sea. Breeding numbers are regularly monitored at many UK seabird colonies (JNCC, 2018), and in the British Isles there have been three comprehensive censuses of breeding seabirds (Mitchell et al., 2004), with a fourth census ongoing 2015-2019. Breeding numbers of many seabird species in the British Isles are declining, especially in the northern North Sea (Foster and Marrs, 2012; JNCC, 2016; MacDonald et al., 2015). In Wales, populations of many seabird species have seen stable or increasing trends, including guillemot, razorbill, puffin, Arctic tern and Sandwich tern (Bladwell et al., 2018). However, declines have been measured in Wales for other species, such as common tern, kittiwake, shag and gannet.

39. Climate change is likely to be the strongest influence on seabird populations in coming years, with anticipated deterioration in conditions for breeding and survival for most species of seabirds (Burthe et al., 2014; Capuzzo et al., 2017; MacDonald et al., 2015). Further declines in numbers of many UK seabird populations are therefore anticipated in the short, medium and long term under a scenario with continuing climate change due to increasing levels of greenhouse gases in the atmosphere.

40. In general, important prey fish stock for seabirds during the breeding season have been depleted by high levels of fishing effort (Lindegren et al., 2018). It is possible that differences in the levels of fishing activity, and/or the slightly different prey items favoured by some species in different locations around the UK has enabled some populations to continue to expand whilst others have declined (Anderson et al., 2014), though the mechanisms controlling population growth and decline are complex and likely influenced by a combination of many factors.

41. Fisheries management will have a strong influence on future seabird populations. The Common Fisheries Policy (CFP) Landings Obligation ("discard ban") will further reduce food supply for scavenging seabirds such as great black-backed gull, lesser black-backed gull, herring gull, fulmar, kittiwake and gannet (Bicknell et al., 2013; Foster et al., 2017; Votier et al., 2013). Other recent changes in fisheries management that aid recovery of predatory fish stock biomass are likely to further reduce food supply for seabirds that feed primarily on small fish such as sandeels, which are a key prey item of a range of predatory fish (Frederiksen et al., 2007; MacDonald et al., 2015).

42. The following paragraphs briefly consider the possible impacts of these factors on some of the marine ornithology receptors.

43. Fulmars, terns, common guillemot, razorbill and puffin appear to be highly vulnerable to climate change, and this, coupled with increasing pressure on the habitats favoured by such species, means that numbers are likely to decline over the coming decades (Burthe et al., 2014). Declines in shag numbers are likely to continue as they are adversely affected by climate change, and will also suffer due to low abundance of prey species and especially by stormy and wet weather

conditions in winter which are predicted to increase as a result of climate change (Burthe et al., 2014; Frederiksen et al., 2008).

44. Most red-throated divers and common scoters wintering in the western British Isles originate from breeding areas at high latitudes in Greenland (Furness, 2015), which may possibly decrease in future if warming conditions make other more northern areas more favourable as a wintering area for those species so that they do not need to migrate as far as UK waters.

45. Future decreases in kittiwake breeding numbers are likely to be particularly pronounced, as it has been demonstrated that kittiwakes are very sensitive to climate change (Carroll et al., 2015; Frederiksen et al., 2012a), and to fishery impacts on sandeel stocks near breeding colonies (Carroll et al., 2017; Frederiksen et al., 2004). The species will also lose the opportunity to feed on fishery discards as the discard ban comes into effect.

46. It is likely that further redistribution of breeding herring gulls and lesser black-backed gulls will occur into urban environments (Rock and Vaughan, 2013), although it is unclear how the balance between terrestrial and marine feeding by these gulls may alter over coming years.

47. Gannet numbers may continue to increase as they have in many parts of the UK over recent years, but evidence suggests that this increase is slowing (Murray et al., 2015), and it is therefore likely that numbers may peak in the near future. In Wales, declines are already apparent (Bladwell et al., 2018). While the fisheries discard ban will reduce discard availability to gannets in European waters, in recent years increasing proportions of adult gannets have wintered in west African waters rather than in UK waters, possibly because there are large amounts of fish discarded by west African trawl fisheries and decreasing amounts available in the North Sea (Garthe et al., 2012; Kubetzki et al., 2009). The apparent flexible behaviour and diet of gannets may reduce their vulnerability to changes in fishery practices or to climate change impacts on fish communities relative to other seabird species.

48. Some anthropogenic impacts on seabirds are amenable to effective mitigation (Brooke et al., 2017; Ratcliffe et al., 2009), but the scale of efforts to reduce these impacts on seabird populations has been small by comparison with the major influences of climate change and fisheries. The conclusion must therefore be that with the possible exception of gannet, numbers of almost all other seabird species across many areas of the UK will most likely be on a downward trend over the next few decades, due to population declines, redistributions, or a combination of both.

49. The EcIA of marine ornithology receptors is therefore carried out against a wider backdrop of recent declining baseline populations of a number of receptor species on a national and international level, with further declines expected in the years to come. Marine ornithology receptors that have experienced growing or stable populations in recent years are viewed by the assessment as possibly being more robust to predicted impacts. Where a receptor species is declining, the assessment considers whether a given impact is likely to exacerbate a decline in the relevant reference population and prevent a receptor species from recovery should environmental conditions become more favourable. For example, seabird populations around much of the UK are expected to experience food shortages due to depletion of fish stocks in the future, potentially affecting the robustness of those populations to environmental change.

50. Climate change has been identified as the strongest influence on future seabird population trends. In this context it is noted that a key component of global strategies to reduce climate change is the development of low-carbon renewable energy developments such as tidal stream energy.

11.5.7. Assignment of Value to Marine Ornithology Receptors

51. The information described above has been used to assign an importance level to each marine ornithology receptor species according to criteria outlined in **Table 11-8** This is presented in **Table 11-12**.

Table 11-12 Importance Levels Assigned to Marine Ornithology Receptors for Project EcIA

Species	Importance Level Assigned
Arctic tern	High
Common tern	
Gannet	
Guillemot	
Kittiwake	
Manx shearwater	
Puffin	
Razorbill	
Sandwich tern	
Black-headed gull	Medium
Common scoter	
Herring gull	
Lesser black-backed gull	
Red-throated diver	
Shag	
Common gull	Low
Cormorant	
Fulmar	
Great black-backed gull	
Mediterranean gull	
Eider	Negligible

11.6. IMPACT ASSESSMENT

11.6.1. Introduction

52. The following assessment provides details of all direct and indirect impacts identified during scoping and those which have been noted as the EIA has progressed. Impacts have been assessed within the stage of the Project at which they will occur (construction, operation / repowering and decommissioning).

53. At the beginning of each section relating to a particular impact pathway, pertinent information and assumptions relating to this impact which have been taken from **Chapter 4, Project Description**, are presented.

11.6.2. Embedded Mitigation

54. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible.

55. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process (see **Chapter 4, Project Description** for further details). A range of different information sources has been considered as part of embedding mitigation into the design of the project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

56. Embedded mitigation relevant to Marine Ornithology is as follows;

- The PDE for tidal devices defined using parameters available from established tidal device technologies, which has been assumed will be developed sufficiently for commercial use at time of deployment. These have been incorporated in the modelling outlined in **Section 11.6.6.3**.

11.6.3. Overview of Potential Impacts

57. Potential impacts to be included within the EcIA have been agreed through consultation on a Ornithological Assessment Approach document with NRW during Ornithology TWG meetings. They are as follows:

- During the construction, and installation phase:
    1. Direct effects due to airborne noise and visual disturbance and displacement to birds in and immediately adjacent to the MDZ due to installation of tidal device foundations and hubs (due to activities such as drilling, or installation of anchors or gravity base structures), construction activities (e.g. activities such as seabed preparation, inter array, export, and cable tail installation and protection), and vessel activity;
    2. Direct effects due to disturbance and displacement at breeding sites (e.g. by vessels moving to and from the site, along the routes of export cables and tails, and near the export cable landfall itself);
    3. Indirect effects due to changes in prey availability (due to underwater noise resulting in disturbance, temporary loss of seabed habitat due to increased suspended sediment concentrations and sediment re-deposition, or permanent loss due to installation of seabed mounted devices and other infrastructure); and
    4. Direct and indirect effects due to changes in water quality (due to increased suspended sediments, or accidental release of contaminants from vessels).
- During the operation and maintenance (O&M) and repowering phase:
    5. Direct effects due to airborne noise and visual disturbance and displacement to birds in and immediately adjacent to the MDZ due to maintenance and repowering

activities (e.g. activities such as cable reburial and additional cable protection), vessel activity and operational tidal devices (including the presence of artificial lighting during darkness);

6. Indirect effects due to changes in prey availability (due to underwater noise resulting in disturbance and displacement, temporary loss of seabed habitat due to increased suspended sediment concentrations and sediment re-deposition underwater noise, disturbance and displacement, loss of seabed habitat, introduction of hard substrate such as foundations, cable and scour protection, or changes to water quality and electromagnetic fields;
7. Direct and indirect effects due to changes in water quality (due to increased suspended sediments, or any accidental release of contaminants from tidal devices or vessels);
8. Direct effects due to collision risk with tidal devices; and
9. Direct effects due to entanglement with tidal devices or the moorings associated with them.

- During the decommissioning phase:

10. Impacts comparable to those listed for the construction and installation phase are anticipated.

58. It should be noted that due to the nature of the Project, construction and operation / repowering phases will overlap much of the time during the lifespan of the Project, meaning that potential impacts could be additive. This has been accounted for by the assessment.

11.6.4. Impacts Screened Out

59. A number of potential impacts were considered for inclusion in the impact assessment but were screened out on the basis that no impacts will occur on marine ornithology receptors. A summary justification is provided in the following paragraphs.

60. Direct impacts due to habitat loss following the installation of tidal devices will occur. However, the extent of direct habitat loss is typically likely to be very low in comparison to the foraging range of the marine ornithology receptors (Cleasby et al., 2018; Oppel et al., 2018; Thaxter et al., 2012). Any direct impact on marine ornithology receptors is considered to be imperceptible and this impact is therefore screened out.

61. Direct impacts due to underwater noise during construction and operation / repowering have been screened out of the assessment. Percussive piling will not be used any stage of the Project in the marine environment, and there is no suggestion from other marine projects that the levels of noise produced by other activities which may occur during the Project could produce sufficient underwater noise to result in impacts on marine ornithology receptors.

62. Barrier effects relating to offshore wind farms and birds in flight has been studied in detail (Dierschke et al., 2016; Masden et al., 2010, 2009). Because the vast majority of infrastructure associated with the Project will occur underwater, and any floating devices will only protrude a maximum of six metres from the surface of the sea (as opposed to 100 m+ in the case of offshore

wind farms), it is not predicted that the Project will cause barrier effects on marine ornithology receptors.

11.6.5. Potential Impacts During Construction and Installation

11.6.5.1. Airborne Noise and Visual Disturbance / Displacement

11.6.5.1.1. Introduction

63. The construction and installation phase of the Project has the potential to affect marine ornithology receptors through disturbance and displacement due to airborne noise and visual disturbance, leading to displacement of birds from subtidal construction sites.

64. Any impacts resulting from this impact pathway would be spatially restricted to subtidal areas within close proximity to the activities, and temporally restricted to the duration of construction activity.

65. Impacts are based on the following predicted average levels of vessel activity, although there will variations in the level of effort over the period of works beyond the average:

- 1 x vessel group in Abraham's Bosom area (ECC) installing cable tails; one-off event of 20 days per cable, up to nine cables, assuming no more than one cable installation per year;
- 1 x vessel group in ECC installing export cables; up to nine events (one per cable) of 20 days each (simultaneous with cable protection installation); assuming no more than one cable installation per year;
- 1 x vessel group in ECC installing export cable protection; up to nine events (one per cable) of 12 days each (simultaneous with export cable installation); assuming no more than one cable installation per year;
- 1 x vessel group in MDZ installing inter-array cables; approximately 111 days per year for ten years;
- 1 x vessel group in MDZ installing hubs; active anywhere in MDZ for up to 180 days per year for up to ten years; and
- 2 x vessel groups in MDZ installing devices; active anywhere in MDZ all year round.

66. Based on information provided in **Chapter 4, Project Description**, it is assumed that up to four vessels or groups of vessels operating in close proximity to one another, could be present within the MDZ at any one time. In the ECC, it is predicted that a maximum of three groups of vessels could be present at any time. As a worst case, the EcIA assumes activity to be continuous because seabed drilling at night during construction and installation is possible.

67. As activities are expected to occur in the MDZ for much of the 37 year lifespan of the Project, this impact is considered to consist of a large number of short term, temporary and reversible impacts over an overall time period which is defined as long term.

68. As activities are expected to occur in the ECC for a small number of days each year, for up to a maximum of ten years, this impact is considered to consist of a modest number of short term, temporary and reversible impacts over an overall time period which is defined as medium term.

11.6.5.1.2. Receptor Sensitivity

69. There is substantial interspecific variation in the sensitivity of marine ornithology receptors to airborne noise and visual disturbance stimuli. In order to focus the assessment, a detailed literature review was carried out regarding susceptibility to disturbance and displacement, which fed into a screening exercise to identify those species most likely to be at risk (**Table 11-13**).

Table 11-13 Screening Exercise Undertaken for Potential Disturbance and Displacement Impacts During Construction of the Project

Species	Sensitivity to Disturbance and Displacement[1]	Screening Result (In or Out)	Justification
Arctic tern	Low	Out	Low susceptibility to disturbance
Black-headed gull	Low	Out	Low susceptibility to disturbance
Common gull	Low	Out	Low susceptibility to disturbance
Common scoter	Very High	Out	Only recorded occasionally (5/24 surveys), always in flight, and usually in coastal locations
Common tern	Low	Out	Low susceptibility to disturbance
Cormorant	High	Out	Only recorded occasionally (2/24 surveys) in very low numbers, always in flight
Eider	Unknown	Out	Recorded on only one baseline survey
Fulmar	Low	Out	Low susceptibility to disturbance
Gannet	Low	Out	Low susceptibility to disturbance
Great black-backed gull	Low	Out	Low susceptibility to disturbance
Guillemot	Medium	In	Potentially susceptible to disturbance and abundant in MDZ; screened in
Herring gull	Low	Out	Low susceptibility to disturbance
Kittiwake	Low	Out	Low susceptibility to disturbance
Lesser black-backed gull	Low	Out	Low susceptibility to disturbance
Manx shearwater	Low	Out	Low susceptibility to disturbance
Mediterranean gull	Low	Out	Low susceptibility to disturbance
Puffin	Medium	In	Potentially susceptible to disturbance and abundant in MDZ; screened in
Razorbill	Medium	In	Potentially susceptible to disturbance and relatively abundant; screened in
Red-throated diver	Very High	In	Recorded infrequently (8/24 surveys) and in low numbers but screened in on a precautionary basis due to sensitivity to impact
Sandwich tern	Low	Out	Low susceptibility to disturbance
Shag	Medium	In	Recorded infrequently (8/24 surveys) and in low numbers but screened in on a

Species	Sensitivity to Disturbance and Displacement[1]	Screening Result (In or Out)	Justification
			precautionary basis due to sensitivity to impact
Notes [1]based on information contained in literature			

70. Based on information from the literature review, there is potential for disturbance and displacement of guillemot, puffin, razorbill, red-throated diver and shag. All other marine ornithology receptors have been assigned a "negligible" sensitivity level according to the definitions in **Chapter 5, EIA Methodology**.

71. Guillemot and razorbill both fall into the "medium" sensitivity category with respect to disturbance and displacement by boat and helicopter traffic (Bradbury et al., 2014; Furness et al., 2013, 2012; Garthe and Hüppop, 2004). Puffin is considered slightly less sensitive than guillemot and razorbill, and shag slightly more sensitive, whilst red-throated diver is considered to be very sensitive (Furness et al., 2013, 2012; Garthe and Hüppop, 2004).

72. On this basis, the following sensitivities to this impact pathway have been allocated according to the definitions in **Chapter 5, EIA Methodology**:

- **Medium** for red-throated diver and shag;
- **Low** for guillemot, puffin and razorbill; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.5.1.3. Magnitude of Impact

73. Various papers have presented scoring systems for disturbance factors applied to seabird species for offshore wind farms (Furness et al., 2013; Furness and Wade, 2012; Garthe and Hüppop, 2004) and other marine energy developments (Furness et al., 2012). The approach uses information in the scientific and 'grey' literature, as well as expert opinion to identify disturbance ratings for individual species (of which much evidence relate to disturbance from vessel activities), alongside scores for habitat flexibility and conservation importance. These factors were used to define an index value that highlights the sensitivity of a species to disturbance and displacement. In the case of several of these examples, extensive peer-review on the initial ratings was employed to ensure that consensus from the wider ornithological research community was reached.

74. Studies examining the effects of the construction and operation / repowering of a range of offshore wind farms (APEM, 2017; Dierschke et al., 2016; Gill et al., 2018; Leopold et al., 2013; Vallejo et al., 2017; Vanermen et al., 2015) have been consulted to assess potential disturbance and displacement impacts, along with a wider review of the impact of a range of marine activities (MMO, 2018).

75. Rather than resulting in direct harm to the bird and loss from the population, disturbance and displacement by airborne noise and visual disturbance will result in affected birds temporarily

redistributing at sea and moving to an area where they are undisturbed, with birds expected to return to the area once activities have ceased.

76. Lighting of construction sites, vessels and other structures at night may potentially be a source of attraction (phototaxis), for some species, or displacement in others. The areas affected would be very small and restricted to subtidal construction areas; for this reason, it is considered that in general, the marine ornithology receptors would be insensitive to this impact. Phototaxis can be a serious hazard for fledglings of some seabird species, predominantly shearwaters (Deppe et al., 2017; Raine et al., 2007; Rodríguez et al., 2017, 2014), but occurs over short distances (typically hundreds of metres) in response to bright white light close to breeding colonies, and once a year when fledglings are departing their breeding colonies. Construction sites associated with the Project would be far enough removed from any Manx shearwater breeding colonies (approximately 45 km) for as to render the likelihood of this impact occurring negligible.

77. The levels at which this impact could result in direct mortality to these species has been quantitatively assessed based on a method advocated for displacement by offshore wind farms (UK SNCBs, 2017), using the maximum recorded MDZ densities in relevant seasons presented in **Appendix 11.2** (**Volume III**). The use of maximum recorded densities ensures that this is a worst case, highly precautionary approach to the assessment of this impact.

78. On a highly precautionary basis, it is predicted that guillemot, puffin and razorbill on the sea may be disturbed or displaced from an area within 300 m of each group of construction vessels, shags on the sea from 500 m of each group of construction vessels, and red-throated divers on the sea from 2 km of each group of construction vessels. These distances are based upon the following sources: professional judgement; information on the numbers of birds recorded on the sea in the vicinity of the survey vessel during baseline surveys both here and at many projects elsewhere (i.e. within 300 m); and published literature on disturbance (Camphuysen et al., 2004; Furness et al., 2013, 2012).

79. The method of the UK SNCBs (2017) requires that estimates of % displacement from the disturbance zone and % of mortality within displaced birds are made. The assessment has been based on recent estimates used during the assessment of impacts for offshore wind farms (e.g. the East Anglia TWO offshore wind farm, (Scottish Power Renewables, 2019)), adjusted to account for the differing scale and likely impact magnitude of the activities occurring during the construction of the Project, which will utilise smaller vessels than the offshore wind projects, and will not utilise percussive piling. When selecting these values, the fact that there is existing vessel traffic using the MDZ (**Chapter 15, Shipping and Navigation**) and the wider area, which based on the results of the baseline surveys (**Appendices 11.1 and 11.2, Volume III**) and latest colony counts and population trends in the local area (JNCC, 2018), does not appear to result in high seabird mortality, has also been considered.

80. **Table 11-14** presents the average numbers of birds within the total displacement zone of four groups of construction vessels, based on maximum single density recorded in the MDZ and 2 km buffer zone for the relevant season (**Table 11-9**), along with the selected displacement and mortality values.

Table 11-14 Numbers of Species Screened into Disturbance and Displacement Assessment that will Occur Within Construction Vessel Disturbance Zone, Assuming Seven Groups of Vessels on Site Simultaneously, Based on Maximum Densities in MDZ and 2 km Buffer (MDZ only for guillemot and razorbill), and % Displacement and Mortality Values Used for Assessment

Species	Disturbance distance (km)	Birds in disturbance zone (breeding)	Birds in disturbance zone (non-breeding)	% of birds in disturbance zone displaced	% of mortality in displaced birds
Guillemot	0.3	100.10	13.16	30-70	0-5
Puffin	0.3	0.77	0	30-70	0-5
Razorbill	0.3	12.19	8.92	30-70	0-5
Red-throated diver	2	24.01		100	0-5
Shag	0.5	2.12	0	60-100	0-5

81. Total levels of seabird mortality anticipated as a result of airborne noise and visual disturbance during the construction of the Project in both the MDZ and ECC are presented in **Table 11-15**.

82. During the breeding season (**Table 11-9**), mortality due to displacement is predicted only for guillemot, a maximum of 4 birds at 70 % displacement and 5 % mortality. Outside the breeding season (**Table 11-9**), mortality is predicted only for red-throated diver (a maximum of 1 bird at 100 % displacement and 5 % mortality) due to this impact pathway.

Table 11-15 Anticipated Seabird Mortality Levels Predicted Due to Airborne Noise and Visual Disturbance in the MDZ and ECC During Construction of the Project (based on parameters presented in Table 11-14)

Species	Mortality in a single breeding season	Mortality in a single non-breeding season
Guillemot	0-4	0
Puffin	0	0
Razorbill	0	0
Red-throated diver	0	1
Shag	0	0

83. Due to the very low levels of mortality predicted as a result of airborne noise and visual disturbance during construction in the MDZ and ECC, an impact magnitude of **Low negative** is considered appropriate for guillemot, with a **Negligible** impact magnitude considered appropriate for all other species.

11.6.5.1.4. Impact Significance

84. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Minor adverse** for guillemot; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull puffin, razorbill, red-throated diver, Sandwich tern and shag.

11.6.5.2. Disturbance at Breeding Sites

11.6.5.2.1. Introduction

85. The construction phase of the Project has the potential to affect marine ornithology receptors at nearby breeding colonies due to airborne noise and visual disturbance caused by vessels laying inter array cables and export cables working within the MDZ, and vessels working in the ECC, where array export cables will be installed. Part of the ECC is within the Abraham's Bosom bay, which is where the Project export cable tails will be installed, and the cables will make landfall. There is also potential for disturbance to occur at breeding locations due to airborne noise and visual disturbance from terrestrial and intertidal based activities at the landward side of the cable landfall.

86. Any impacts from cable laying activities (both subtidal and at the landward (including intertidal) side of the landfall) would be will be spatially restricted to areas within close proximity to the activities, and temporally restricted to the duration of construction activity.

87. Impacts are based on the following predicted levels of vessel activity:

- 1 x vessel group in Abraham's Bosom area (ECC) installing cable tails; one-off event of 20 days per cable, up to nine cables, assuming no more than one cable installation per year;
- 1 x vessel group in ECC installing export cables; up to nine events (one per cable) of 20 days each (simultaneous with cable protection installation); assuming no more than one cable installation per year;
- 1 x vessel group in ECC installing export cable protection; up to nine events (one per cable) of 12 days each (simultaneous with export cable installation); assuming no more than one cable installation per year;
- 1 x vessel group in MDZ installing inter-array cables; approximately 111 days per year for ten years;
- 1 x vessel group in MDZ installing hubs; active anywhere in MDZ for up to 180 days per year for up to ten years; and
- 2 x vessel groups in MDZ installing devices; active anywhere in MDZ all year round.

88. Based on information provided in **Chapter 4, Project Description**, it is assumed that up to four vessels or groups of vessels operating in close proximity to one another, could be present within the MDZ at any one time. In the ECC, it is predicted that a maximum of three groups of vessels could be present at any time. As a worst case, the EcIA assumes activity to be continuous because seabed drilling at night during construction and installation is possible.

89. As activities are expected to occur in the MDZ for much of the 37 year lifespan of the Project, this impact is considered to consist of a large number of short term, temporary and reversible impacts over an overall time period which is defined as long term.

90. As activities are expected to occur in the ECC for a small number of days each year, for up to a maximum of ten years, this impact is considered to consist of a modest number of short term, temporary and reversible impacts over an overall time period which is defined as medium term.

91. For the purposes of this assessment it is assumed that terrestrial and intertidal works at the landward side of the landfall could occur during a period of 18 months. All landfall locations (**Chapter 4, Project Description**) are in excess of 500 m from the nearest seabird colony (Abraham's Bosom).

11.6.5.2.2. Receptor Sensitivity

92. There are a wide range of disturbance and/or standoff distances for seabird colonies in published literature, including a standoff distance of 180 m for mixed tern/skimmer colonies disturbed by pedestrians and boats (Rodgers Jr. and Smith, 1995), a maximum flight initiation distance of 78 m for yellow-legged gull colonies to pedestrian approach (Martinez-Abrain et al., 2008), and a 100 m standoff distance between tern colonies and motor boats (Burger, 1998). A mixed colony of fulmars, shags, herring gulls, kittiwakes, guillemots, razorbills and puffins in Scotland demonstrated virtually no reaction behaviourally or reproductively to flights by fixed-wing aircraft within 100 m of the colony (Dunnet, 1977). A range of marine codes suggest that safe standoff distances for seabird colonies around the UK range from several tens of metres up to 200 m.

93. A more detailed study found that individuals within mixed seabird colonies where guillemot was the most abundant species elicited a range of disturbance responses due to close passing vessels (Rojek et al., 2007). Nearly all vessel disturbances to guillemots and cormorants occurred at vessel distances of less than 100 m from the colony. Of all recorded disturbance events, 78 % occurred when boats approached within 50 m of the colony, and all flushing events occurred due to vessels within 75 m of the colony. Heads up responses occurred occasionally when boats approached to within 200 m. This reaction does not necessarily result in the loss of eggs or chicks but can lead to flushing if the disturbance source continues or worsens.

94. Flushing during incubation or chick-rearing can lead to egg or chick loss because of displacement from the breeding site and abandonment (either temporary or permanent), egg breakage or predation. The effects of flushing on birds that are not attending eggs or chicks include disruption of courtship, nest-site defence or prospecting activities.

95. Based on the existing literature it is concluded that the presence of construction vessels will only result in effects on seabirds at breeding colonies if vessels regularly approach them to distances of less than approximately 300 m, which is considered a highly precautionary position on the basis of the information described above. There are several seabird colonies that could potentially be sensitive to this impact (based on distance to the Project), which are classified differently depending on the source material used. According to the SMP, there are sub-colonies located at Gogarth, Abrahams Bosom, and South Stack (**Table 11-8**). The RSPB reports colonies within the South Stack reserve slightly differently, with guillemots and razorbills being recorded in 2018 at Penlas North, Mousetrap Buttress, Redwall Buttress, South of Bridge, North of Bridge, and South Stack Island. Whilst not detailed here, the RSPB counts reported herring gull (338 individuals), fulmar (27 individuals), lesser black-backed gull (73 individuals), cormorant (10 individuals), kittiwake (5 individuals), and puffin (5 individuals).

96. It is considered that all breeding seabird locations on the Holy Island Coast are medium value receptors.

97. The latest counts for the three seabird colonies identified above are provided in **Table 11-16**.

Table 11-16 Latest Colony Counts at Breeding Seabird Colonies Closest to MDZ from SMP Database and RSPB

Colony (and RSPB colonies that lie within it in brackets)	Approximate Central Grid Reference Based on SMP Data	Latest Count Date in SMP	Results of latest SMP Count (individuals on land)	Results of June 2018 RSPB Count (mean of minimum five counts; individuals on land)
Abraham's Bosom (Penlas)	SH 20907 81489	June 2016	Guillemot (315) Razorbill (83) Fulmar (2) Herring gull (2)	Razorbill (11)
South Stack and Penlas RSPB (South of Bridge, Mousetrap Buttress, Redwall Buttress, South Stack Island)	SH 20599 82004	May 2018	Guillemot (5,243) Razorbill (994) Herring gull (106) Fulmar (11) Lesser black-backed gull (9) Shag (8) Kittiwake (7) Puffin (7)	Guillemot (9,690) – of which 3,398 were on South Stack island Razorbill (1,297) – of which 133 were on South Stack island
Gogarth (North of Bridge)	SH 21513 83286	June 2016	Herring gull (26) Razorbill (18) Cormorant (13) Guillemot (7) Fulmar (5) Shag (5) Lesser black-backed gull (3)	Razorbill (28)

98. For simplicity, the JNCC SMP notation will be used for these colonies for the remainder of this assessment. However, because of the larger number of visits, it is possible that RSPB auk counts within the reserve may be more accurate than those contained within the SMP.

99. The approximate distance between the colonies and various working areas is provided in **Table 11-17**. The relative location of colonies to the nearest working areas is shown on **Figure 11-2** (**Volume II**).

Table 11-17 Approximate Distances between MDZ, ECC, and Key Breeding Seabird Colony Locations within the South Stack and Penlas SMP Master Site

Colony	Approximate Distance to MDZ (m) (nearest boundary)	Approximate Distance to Export Cable Corridor (m) (nearest boundary)	Approximate Distance to Cable Tail Work Area (m) (nearest boundary)	Approximate Distance to Landward Landfall Location (m) (nearest boundary)
Abraham's Bosom	950	0	0-500	500 (minimum)
South Stack and Penlas RSPB	770	20	>1000	>1000
Gogarth	700	270	>1000	>1000

100. Provided that construction vessels are aware of the location of seabird colonies, do not propose to operate within 300 m of colony locations for extended periods (i.e. periods of several days without working elsewhere), and follow best practice for operating in relatively close proximity to such features, which will be included in a Construction and Environment Management Plan (CEMP), it is concluded that the Abraham's Bosom, South Stack and Penlas RSPB and Gogarth seabird colonies will have a **Negligible** sensitivity to cable laying and associated vessels working within the MDZ and ECC during the construction phase of the Project according to the definitions in **Chapter 5, EIA Methodology**.

101. If there are vessels which are involved in the installation of export cables or the export cable tails within 300 m of the Gogarth, Abrahams Bosom and South Stack seabird colonies during the breeding season for extended periods of time, then the sensitivity of the breeding colonies increases to **Medium**, based on the definitions provided in **Chapter 5, EIA Methodology**. The core breeding seasons are considered to be March to July for Abraham's Bosom (whilst breeding fulmar are present, they are present in low numbers only and are highly tolerant of vessel activity (Furness et al., 2012; Garthe and Hüppop, 2004)), and February to August for South Stack and Gogarth based on the species present at the last count (JNCC, 2018). During the non-breeding season, the sensitivity is **Negligible**, as most of the individuals associated with the colony will not be present, and the consequences of birds being flushed when not incubating an egg or raising a chick are significantly lower than in the breeding season.

102. Due to the distance between the landward landfall location and the Gogarth, Abrahams Bosom and South Stack seabird colonies (at least 500 m), these colonies will have a **Negligible** sensitivity to works at this location.

11.6.5.2.3. Magnitude of Impact

103. Any impacts resulting from the activities in the export cable corridor would be short-term, temporary and reversible in nature, lasting only for the duration of construction activity. Despite this, a severe one-off disturbance event at a seabird colony has the potential to cause a serious population-level effect.

104. Provided that construction vessels are aware of the location of seabird colonies, do not operate within 300 m of these locations during the breeding season, and follow best practice for operating in relatively close proximity to such features, which will be included in a Construction and Environment Management Plan (CEMP), it is concluded that vessels working within the MDZ and ECC will not cause any impacts on seabird breeding colonies during the construction phase of the Project. This applies to all inter array cable works, and export cable works occurring within the MDZ. The impact magnitude is therefore **Negligible**. This also applies to the non-breeding season.

105. Any vessel operating within 300 m of a breeding seabird colony during the breeding season has the potential to cause a **Medium negative** impact magnitude.

106. Due to the distance between the landward landfall location and the and the Gogarth, Abrahams Bosom and South Stack seabird colonies, along with the nature of the activities that will occur, the magnitude of impact of works at this location is **Negligible**.

11.6.5.2.4. Impact Significance

107. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Medium adverse** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating within 300 m of the colonies during the breeding season; and
- **Negligible** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating in excess of 300 m from the colonies, within 300 m during the non-breeding season, and works at the landward landfall.

11.6.5.2.5. Mitigation and Residual Impact

108. Based on the species known to breed at each of the potentially affected colonies (**Table 11-16**), and excluding any species understood to possess a "low" sensitivity to disturbance and displacement when at sea (**Table 11-13**), it is considered that it is appropriate to prohibit all vessel activities within 300 m of each of these colonies during the breeding season (**Table 11-9**) unless an ecological professional present states it is acceptable to proceed, which may be the case depending on the species present, the breeding stage, or the nature of vessel activities. This breeding period is considered to be March to July for Abraham's Bosom and February to August for South Stack and Gogarth based on the presence of shag at the last count for the latter two colonies (JNCC, 2018).

109. If this measure is adopted, then the magnitude of impact can be reduced from "medium" to "low" during the breeding season as works will not be permitted where an ecological professional considers sensitivity to be too high to enable works (e.g. works within 300 m may not be able to occur when most individuals at a colony are in the incubation stage). The residual impact significance is therefore **Minor adverse**.

11.6.5.3. Other Impacts

11.6.5.3.1. Introduction

110. Indirect impacts on marine ornithology receptors may occur during the construction phase if there are impacts on prey species and/or the habitats of prey species. These include those resulting from the production of underwater noise and the generation of suspended sediments that may alter the behaviour, abundance or availability of prey species for seabirds. There is also the possibility of pollution incidents due to ejection of contaminants or accidents involving construction vessels, which could result in potential indirect (prey effects) and direct (direct contact) impacts on marine ornithology receptors. Both are covered in this section.

11.6.5.3.2. Receptor Sensitivity

111. Underwater noise may cause fish and mobile invertebrates to avoid construction areas and their immediate surroundings, and also affect their physiology and behaviour. Suspended sediments may cause fish and mobile invertebrates to avoid construction areas and their immediate surroundings and may smother and hide immobile benthic prey in a localised area. These mechanisms may result in less prey being available within the construction area and immediate surrounding area to foraging seabirds. Pollution events may cause localised injury or mortality to seabirds or their prey species in the immediate vicinity of the source of the pollution. All of these effects, if they occurred, would be extremely localised.

112. Generally speaking, seabirds are mobile animals. In the breeding season they adopt a central place foraging strategy from the nest, restricting their foraging areas to enable them to successfully provision their chicks. In the non-breeding season, birds may be sedentary, remaining in the area where they bred, dispersive, or fully migratory. The high mobility of seabirds means that they are able to utilise alternative areas of habitat should an area of habitat within their range become unavailable. Habitat flexibility is also an important criterion in determining the ability of a particular species to find alternative foraging habitat, and whilst a qualitative measure, it has been reviewed by several sources (Furness et al., 2012; Furness and Wade, 2012; Garthe and Hüppop, 2004).

113. **Table 11-18** presents habitat flexibility of the marine ornithology receptors (Furness et al., 2012), along with sensitivity to these impacts using the definitions in **Chapter 5, EIA Methodology**, based on expert judgement.

Table 11-18 Habitat Flexibility and Sensitivity of Marine Ornithology Receptors to Indirect (Prey and Pollution) and Direct Pollution Impacts

Species	Habitat Flexibility (Scored 1-5 by Furness et al., (2012), where 1 is the most flexible)	Predicted Sensitivity to Localised Prey or Pollution Events
Common scoter	4	**Low**
Eider	4	
Red-throated diver	4	
Arctic tern	3	
Common tern	3	
Cormorant	3	
Guillemot	3	
Puffin	3	
Razorbill	3	
Sandwich tern	3	
Shag	3	
Black-headed gull	2	**Negligible**
Common gull	2	
Great black-backed gull	2	
Kittiwake	2	
Mediterranean gull	2 (assumed same as black-headed gull)	
Fulmar	1	

Species	Habitat Flexibility (Scored 1-5 by Furness et al., (2012), where 1 is the most flexible)	Predicted Sensitivity to Localised Prey or Pollution Events
Gannet	1	
Herring gull	1	
Lesser black-backed gull	1	
Manx shearwater	1	

11.6.5.3.3. Magnitude of Impact

114. With regard to noise impacts, **Chapter 10, Fish and Shellfish Ecology** and **Chapter 14, Commercial Fisheries** discuss the potential impacts upon fish relevant to marine ornithology as prey species. For species such as herring, sprat and sandeel, which are prey items of several marine ornithology receptors, the impact magnitude of underwater noise effects (physical injury or behavioural changes) and habitat loss during construction is considered to be minor or negligible. With regard to the definitions of impact magnitude given in **Chapter 5, EIA Methodology**, it is concluded that the magnitude of impact on seabirds occurring in or around the Project during the construction phase is **Negligible**. This applies to direct effects on the marine ornithology receptors themselves (**Section 11.6.4**), and their prey.

115. With regard to changes to the seabed and to suspended sediment levels, **Chapter 7, Metocean Conditions and Coastal Processes** and **Chapter 9, Benthic and Intertidal Ecology** discuss the nature of any change and impacts on the seabed and benthic habitats which host or support seabird prey species. The maximum envisaged effect associated with sediment plumes arising from the construction phase occurs during the foundation installation activities, which will cause only very minor increases in suspended sediment concentration; less than 1 mg/l a short distance from the release point, over a distance of several hundred metres. The effects will be temporary and fully reversible, with a return to very low background concentrations occurring rapidly upon cessation of installation activities. Other than at the immediate release point, such a change would be immeasurable. It is concluded that the magnitude of impact on seabirds occurring in or around the Project during the construction phase is **Negligible**.

116. Any pollution incidents, which are considered to be unlikely to occur, will result in the contamination of a small area (likely no more than several hundreds of metres) of subtidal habitat with a small amount of pollution. Measures will be in place to rapidly collect or disperse any such contamination, meaning that its presence will be temporary and reversible. As a result, based on the definitions of impact magnitude given in **Chapter 5, EIA Methodology**, the magnitude of impact is considered to be **Negligible**.

11.6.5.3.4. Impact Significance

117. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, guillemot, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull, puffin, razorbill, red-throated diver, Sandwich tern and shag.

11.6.6. Potential Impacts During Operation / Repowering

11.6.6.1. Airborne Noise and Visual Disturbance / Displacement

11.6.6.1.1. Introduction

118. The operational / repowering phase of the Project has the potential to affect bird populations in the marine environment through disturbance due to airborne noise and visual disturbance, leading to displacement of birds from subtidal habitats occupied by arrays of tidal devices. This could be due to the presence of the devices themselves, or maintenance activities on the devices, inter array cables or export cables.

119. With respect to tidal devices, any impacts resulting from this impact pathway would be spatially restricted to subtidal areas within close proximity to the devices, and temporally restricted to the duration of operation / repowering (up to 37 years; long term). A maximum of 130 surface emergent devices may be deployed in total. The worst-case height above sea level for any tidal device will be 6 m.

120. It is expected that annual inspections of all cables will occur for the first three years after installation, reducing to every two years thereafter. Up to ten major cable repairs of five days each may be required throughout the Project life of 37 years. Devices will be visited up to 15 times annually. The assessment therefore assumes that during operation / repowering, approximately four groups of vessels may be present in the MDZ and ECC (the OfDA) at any one time. This is in addition to the vessel groups expected to be present fulfilling construction requirements (**Section 11.6.5.1**).

11.6.6.1.2. Receptor Sensitivity

121. There is limited information available on whether the presence of operational tidal devices causes disturbance and displacement effects on birds, although available literature suggests that either no, or very limited displacement impacts occur as a result of their presence (Lieber et al., 2019; Royal Haskoning, 2011).

122. Robbins (2017) provides an overview of five years of bird observations collected from the Fall of Warness tidal energy test site at the European Marine Energy Centre (EMEC). During that study, a number of species were frequently recorded which are also frequently present in the MDZ. It was noted that species recorded by Robbins (2017) occupied the ecological niches that would be expected based on their known ecology (e.g. guillemots and razorbills showing a preference for pelagic waters). This suggests that bird behaviour had likely remained as would be expected despite the deployment of the tidal devices. In addition, birds that have been classified as particularly susceptible to disturbance by vessel traffic on disturbance by man-made structures at sea (Furness et al., 2013, 2012; Garthe and Hüppop, 2004) such as red-throated diver and shag were also frequently recorded at the site. This suggests that disturbance and displacement effects due to the presence of tidal devices are lower than similar effects caused by vessels.

123. Furness et al. (2012) classified seabird species by their potential for disturbance by marine structures, where a score of one represented minimal risk, and five moderate risk. None of the marine ornithology receptors were scored above three.

124. Of the bird species recorded during the baseline surveys (**Appendix 11.1, Volume III**), cormorant and shag have been observed elsewhere using man-made structures as roosting platforms (Dierschke et al., 2016; Furness et al., 2012; Kahlert et al., 2004; Roycroft et al., 2004). The presence of structures effectively enables extension of the foraging range of these species, enabling them to utilise foraging areas which were previously beyond their maximum range. There is no evidence available regarding the use of surface piercing tidal devices for this purpose, but it is assumed that they will be used in a similar way. Other groups of species that may be attracted into operational arrays due to the presence of roosting platforms are gulls (Dierschke et al., 2016; Roycroft et al., 2007, 2004) and terns (Christensen et al., 2004).

125. Lighting of tidal devices and other structures at night may potentially be a source of attraction (phototaxis) or displacement. The areas affected would mainly be restricted to array areas with the exception of transiting vessels associated with the Project, which would be less common at night. Because the lighting would only affect an extremely localised area, it is considered that in general, the marine ornithology receptors would be insensitive to this impact. Phototaxis can be a serious hazard for fledglings of some seabird species, predominantly shearwaters (Deppe et al., 2017; Raine et al., 2007; Rodríguez et al., 2017, 2014), but occurs over short distances (typically hundreds of metres) in response to bright white light close to breeding colonies, and generally only once a year, when fledglings are departing their breeding colonies. Operational arrays of tidal devices within the MDZ would be far enough removed from any Manx shearwater breeding colonies (approximately 45 km) to render the likelihood of this impact occurring negligible.

126. Combining this information with the results of the screening exercise undertaken in **Table 11-13** results in the following sensitivity classifications with respect to the tidal devices themselves:

- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, guillemot, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull, puffin, razorbill, red-throated diver, Sandwich tern and shag.

127. With respect to vessel activity, it is assumed on a highly precautionary basis that exactly the same levels of impact and mortality are predicted due to operational phase activities as is the case for construction. This is detailed in **Section 11.6.5.1**. The sensitivity levels are as follows:

- **Medium** for red-throated diver and shag;
- **Low** for guillemot, puffin and razorbill; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.6.1.3. Magnitude of Impact

128. Whilst the assessment of receptor sensitivity for this impact pathway draws on literature focusing on the impacts of offshore wind farms, it is not considered that the disturbance and displacement impacts caused by an array of tidal energy converters will be comparable to that of an offshore wind farm due to the obvious differences in physical characteristics between the two above the surface of the sea. Given the very small or even complete absence of tidal devices from the

surface of the sea, a more accurate comparison in terms of displacement effects is probably something more akin to a gill net or a buoy. The well documented bycatch of seabirds (Bicknell et al., 2013; Croxall et al., 2012; Žydelis et al., 2013, 2009), indicates such submerged, or largely submerged structures do not readily disturb birds sufficiently to prevent their entanglement. This assessment also considers that any very minor displacement effects that may occur would likely only be temporary as birds are expected to habituate to the presence of tidal devices.

129. It is concluded from the review of responses of the presence of man-made structures by a range of species in **Section 11.6.6.1.2** that the following magnitudes of impact are appropriate:

- **Low beneficial** for cormorant and shag; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, eider, fulmar, gannet, guillemot, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull, puffin, razorbill, red-throated diver and Sandwich tern.

130. Regarding maintenance activities, any impacts will be spatially restricted to subtidal areas within close proximity to the activities, and temporally restricted to the duration of the activity. These impacts are therefore short-term, temporary and reversible. Rather than resulting in harm to the bird or loss from the population, disturbance and displacement by airborne noise and visual disturbance will result in affected birds temporarily redistributing at sea and moving to an area where they are undisturbed, with birds expected to return to the area once activities have ceased.

131. For the purposes of the assessment it is assumed that levels of activity associated with the operation of the Project are comparable to those anticipated during construction, and as the two project phases are expected to run simultaneously for much of the Project lifespan, the magnitude of impact is the same as detailed in **Section 11.6.5.1.3**. This is:

- **Low negative** for guillemot; and
- **Negligible** for all other species.

11.6.6.1.4. Impact Significance

132. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Minor adverse** for guillemot; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, puffin, Manx shearwater, Mediterranean gull, razorbill, red-throated diver, Sandwich tern and shag.

11.6.6.2. Disturbance at Breeding Sites

11.6.6.2.1. Introduction

133. The operational / repowering phase of the Project has the potential to affect marine ornithology receptors at nearby breeding colonies due to airborne noise and visual disturbance caused by maintenance vessels in the MDZ and ECC.

134. It is expected that annual inspections of all cables will occur for the first three years after installation, reducing to every two years thereafter. Up to ten major cable repairs of five days each may be required throughout the Project life of 37 years. Devices will be visited up to 15 times annually. The assessment therefore assumes that during operation / repowering, approximately four groups of vessels may be present in the MDZ and ECC (the OfDA) at any one time during the lifespan of the Project.

11.6.6.2.2. Receptor Sensitivity

135. Provided that construction vessels are aware of the location of seabird colonies, do not operate within 300 m of colony locations during the breeding season in the absence of prior ecological advice, and follow best practice for operating in relatively close proximity to such features, it is concluded that the Abraham's Bosom, South Stack and Penlas RSPB and Gogarth seabird colonies will have a **Negligible** sensitivity to cable laying and associated vessels working within the MDZ and ECC during the operational / repowering phase of the Project according to the definitions in **Chapter 5, EIA Methodology**.

136. If there are vessels which are involved in the maintenance of export cables or the export cable tails within 300 m of the Gogarth, Abrahams Bosom and South Stack seabird colonies, then the sensitivity of the breeding colonies increases to **Medium**, based on the definitions provided in **Chapter 5, EIA Methodology**. The core breeding seasons are considered to be March to July for Abraham's Bosom (whilst breeding fulmar are present, they are present in low numbers only and are highly tolerant of vessel activity (Furness et al., 2012; Garthe and Hüppop, 2004)), and February to August for South Stack and Gogarth based on the presence of shag at the last count (JNCC, 2018).

11.6.6.2.3. Magnitude of Impact

137. Any impacts resulting from the activities in the export cable corridor would be short-term, temporary and reversible, lasting only for the duration of maintenance activity. Despite this, a severe one-off disturbance event at a seabird colony has the potential to cause a serious population-level effect.

138. Provided that vessels are aware of the location of seabird colonies, do not operate within 300 m of these locations during the breeding season, and follow best practice for operating in relatively close proximity to such features, it is concluded that vessels working within the MDZ and ECC will not cause any impacts on seabird breeding colonies during the construction phase of the Project. The impact magnitude is therefore **Negligible**.

139. Any vessel operating within 300 m of a breeding seabird colony during the breeding season has the potential to cause a **Medium negative** impact magnitude.

11.6.6.2.4. Impact Significance

140. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Medium adverse** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating within 300 m from the colonies; and
- **Negligible** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating in excess of 300 m from the colonies.

11.6.6.2.5. Mitigation and Residual Impact

141. Based on the species known to breed at each of the potentially affected colonies (**Table 11-16**), and excluding any species understood to possess a "low" sensitivity to disturbance and displacement when at sea (**Table 11-13**), it is considered that it is appropriate to prohibit all vessel activities within 300 m of each of these colonies during the breeding season (**Table 11-9**) unless an ecological professional present states it is acceptable to proceed, which may be the case depending on the species present, the breeding stage, or the nature of vessel activities. This breeding period is considered to be March to July for Abraham's Bosom and February to August for South Stack and Gogarth based on the presence of shag at the last count for the latter two colonies (JNCC, 2018).

142. If this measure is adopted, then the magnitude of impact can be reduced from "medium" to "low" during the breeding season as works will not be permitted where an ecological professional considers sensitivity to be too high to enable works (e.g. works within 300 m may not be able to occur when most individuals at a colony are in the incubation stage). The residual impact significance is therefore **Minor adverse**.

11.6.6.3. Collision Risk with Tidal Devices

11.6.6.3.1. Introduction

143. The operational / repowering phase of the Project has the potential to affect marine ornithology receptor populations through collision between diving birds and the tidal energy convertors (TEC) within tidal devices. This is currently a theoretical risk (Furness et al., 2012; McCluskie et al., 2012; SNH, 2016), and no actual effect has yet been demonstrated.

144. For the operational / repowering phase of the Project, collision risk for all regularly diving seabird species recorded on the sea within the MDZ has been assessed using two methods, Encounter Rate Modelling (ERM) and Collision Risk Modelling (CRM), as per published guidance (SNH, 2016) and discussions with the Ornithology TWG during the preparation of this chapter. Full details of the methods, the input parameters, the tidal device deployment scenarios selected for modelling, and detailed outputs are provided in **Appendix 11.3** (**Volume III**). It should be noted that as per SNH (2016), it is acknowledged that the ERM and CRM methods will provide at best, an order of magnitude estimate of collision risk. For several reasons explored in detail in **Appendix 11.3** (**Volume III**), it is also expected that both ERM and CRM provide results that are likely to give a precautionary estimate of theoretical collision risk.

145. For each species, the possibility of a significant proportion of birds at risk of collision being from a single colony, which substantially increases the risk of population level effects on that particular colony (**Table 11-11**), was also considered if ERM/CRM outputs indicated that the species was particularly vulnerable to collision. Where this was identified as a possible issue, the outputs from ERM/CRM have then been used as an input for Population Viability Analysis (PVA) for these colonies. Details of PVA methodology, input parameters and outputs are given in **Appendix 11.3** (**Volume III**).

146. There is considerable uncertainty regarding avoidance rates for several reasons. Firstly, it is expected that animals of relatively small size such as diving seabirds might be swept past moving tidal device blades while entrained within the tidal stream (Wilson et al., 2007). Secondly, given that the rotation speed of tidal stream turbines is generally much lower than wind turbines (where collisions are assumed to result in 100 % collision mortality) (Fraenkel, 2006), and dive and swim speeds of seabirds are much lower than their flight speeds (Alerstam et al., 2007; Bruderer and Boldt, 2001; Robbins, 2017), and that the profiles of tidal device blades are generally ‘blunt’ in profile in contrast to those of wind turbines, it is considered highly unlikely that the strike force of a collision would result in a trauma sufficient to cause injury or death in all collision events (Wilson et al., 2007). This may be particularly applicable to collisions occurring near the centre of rotor, downward strikes occurring on dive descents, and upward strikes occurring on dive ascent. Finally, no information exists on the ability of seabirds to avoid collisions with tidal turbines at any range. It should be noted that the burst speed of some species of diving birds relative to the speed of tidal device turbine blades is thought to be much higher when compared to the equivalent relationships between flying birds and wind turbines (Fraenkel, 2006; Wilson et al., 2007). This suggests that such close-range avoidance behaviour will be more successful in diving seabirds than may be the case for flying birds at wind farms.

147. For balance, it should also be noted that some information suggests that narrow fields of view and/or inability to see great distances underwater may increase the potential vulnerability of diving birds to collision with objects underwater (Martin and Wanless, 2015; White et al., 2007). That being said, no extensive reports of underwater collisions between seabirds and underwater objects have been reported. Whilst seabird bycatch due to entanglement of seabirds in fishing nets is a widely reported issue (Žydelis et al., 2013, 2009), this is considered a separate phenomenon to the theoretical risk of underwater collision presented here.

148. It is recognised that the models used here, and the comparability of their outputs to potential real-world impacts, will be shaped enormously by the avoidance rate that is selected. As suggested by SNH (2016) and agreed with the Ornithology TWG, the avoidance rates 0 %, 50 %, 90 %, 95 %, 98 % and 99 % have been presented, along with higher rates of 99.5 % and 99.9 %. Based on the recommended default collision risk for onshore wind of 98 %, and detail provided above which indicates that higher avoidance rates are appropriate for tidal energy devices, the impact assessment focuses on avoidance rates of between 95 % and 99.9 %.

11.6.6.3.2. Receptor Sensitivity

149. Birds recorded on the water in the MDZ during boat-based surveys (**Appendix 11.1, Volume III**) during relevant seasons (**Table 11-9**), which are known to habitually dive to the depth where there is a risk of collision with TECs will be sensitive to potential collision impacts. These species have been identified by an extensive literature review into their diving capabilities and foraging

activities (**Appendix 11.3, Volume III)**. The species identified are guillemot (breeding and non-breeding), puffin (breeding), razorbill (breeding and non-breeding), red-throated diver (non-breeding), Manx shearwater (breeding), gannet (breeding) and shag (breeding). Whilst it is possible that cormorant (and possibly shag) numbers in the MDZ may increase during operation due to the roosting opportunities provided by floating infrastructure, collision risk cannot be calculated for this species due to the fact it was not recorded on the sea in the MDZ during baseline surveys. For the purposes of this assessment, sensitivity and magnitude have been set at the same level as shag, as the most similar species included in the assessment to cormorant.

150. In addition to species receptors, colonies have been assigned a sensitivity where it is expected that a high proportion of a given species that is sensitive to this impact pathway will be present within the MDZ.

151. Sensitivities to collision, according to the definitions provided in **Chapter 5, EIA Methodology** are as follows:

- **High** for the South Stack and Penlas SMP sub-colonies, as it is expected to be the origin of 100 % of MDZ populations of three diving birds (guillemot, razorbill and shag);
- **Medium** for gannet, guillemot, Manx shearwater, puffin, razorbill, red-throated diver and shag (as well as cormorant, which has not been modelled due to no birds being recorded on the water in the MDZ during boat-based surveys); and
- **Negligible** for all other marine ornithology receptors species listed in **Table 11-10**, as their diving habits identified in the literature mean that they will not routinely occur in the rotor swept zone of tidal devices.

11.6.6.3.3. Magnitude of Impact

152. Collision between a diving seabird and a TEC could occur anywhere within an operational tidal array during the operational / repowering phase, which could last for a total of up to 37 years (i.e. long term). As described above, the likelihood of collisions actually resulting in mortality is somewhat unknown, reflected in a range of avoidance rates being presented for the species of interest (SNH, 2016).

153. Whilst not presented for the purposes of keeping the chapter to a reasonable length, collision estimates using the upper and lower confidence intervals associated with each density are accounted for when assigning magnitudes of impact across the scenarios below.

11.6.6.3.3.1. 240 MW Full Deployment Scenario

154. Several tidal device parameter envelopes, identified by alphanumeric codes, have been considered, each representing a realistic worst case for that particular type of device (**Appendix 11.3, Volume III**). For a 240 MW full deployment of a variety of devices (**Appendix 11.3, Volume III**), the annual number of collisions estimated for each species by time period (breeding and non-breeding season is presented in **Table 11-19**.

Table 11-19 Number of Predicted Collisions in a Single Season (Mean of ERM and CRM) for Diving Species Recorded in MDZ by Appropriate Time Period, at a Range of Different Avoidance Rates, for a Deployment Scale of 240 MW

Species	Time Period (B/NB)	Avoidance Rate (%)							
		0	**50**	**90**	**95**	**98**	**99**	**99.5**	**99.9**
Gannet	B	14	7	2	1	1	1	1	0
Guillemot	B	21,034	10,517	2,103	1,052	421	210	105	21
	NB	5,739	2,869	574	287	115	57	29	6
Manx shearwater	B	186	93	19	9	4	2	1	0
Puffin	B	94	47	9	5	2	1	0	0
Razorbill	B	6,483	3,241	648	324	130	65	32	6
	NB	6,469	3,234	647	323	129	65	32	6
Red-throated diver	NB	612	306	61	31	12	6	3	1
Shag	B	16	8	2	1	0	0	0	0

155. To examine the significance of the values in **Table 11-19**, the predicted number of collisions in a season was compared to the probable reference population (**Table 11-11**). On the basis of information regarding the likely components of an avoidance rate (**Section 11.6.6.3.2** and **Appendix 11.3, Volume III**), the assessment focuses on avoidance rates between 95 % and 99.9 % (**Table 11-20**).

Table 11-20 Collision Rates at 95-99.9 % Avoidance Rates (Mean of ERM and CRM) Relative to Relevant Reference Populations, at a Deployment Scale of 240 MW for a Single Season

Species	Time Period (B/NB)	Reference Population (individual birds) (Table 11-11)	Probable Number of Collisions per Season	As % of Reference Population
Gannet	B	138,474	0 - 1	0 - 0.001
Guillemot	B	7,457	–21 - 1,052	0.28 – 14.11
	NB	1,139,220	–6 - 287	0 - 0.03
Manx shearwater	B	673,350	0 - 9	0 - 0.001
Puffin	B	1,746	0 - 5	0 - 0.29
Razorbill	B	1,467	6 - 324	0.41 - 22.09
	NB	341,422 (Nov-Dec) 606,914 (Aug-Oct and Jan-Mar)	6 - 323	0.002 - 0.09
Red-throated diver	NB	1,676	1 - 31	0.06 - 1.85
Shag	B	26	0 - 1	0 - 3.85

156. Depending on the proportion of guillemots in the MDZ from the South Stack and Penlas SMP sub-colonies versus the wider UK Western Waters BDMPS during the non-breeding season, the upper limit of non-breeding season collisions of 234 birds (at 95 % avoidance) could represent between 0 % to 3.10 % of the South Stack and Penlas SMP sub-colonies breeding adult population, depending on the dispersal rate of birds from this colony following the breeding season. The upper, worst case value of 3.10 % is only applicable if no guillemots disperse from the colony during the non-breeding season, and all collisions involve birds from this colony, which seems highly unlikely. This calculation is highly precautionary as it does not include the

non-breeding component of the SSSI population in the overall population size, and assumes all mortalities are breeding adults.

157. Due to the potentially high number of collisions predicted for guillemot and razorbill, in addition to the fact that 100 % of the MDZ population originates from the same colony, a PVA was carried out on the population of the South Stack and Penlas SMP sub-colonies for both species during the breeding season (encompassing the Gogarth, South Stack and Abraham's Bosom sub-colonies), using the same avoidance rates presented above. PVAs considered the combined predicted effects of mortality from collisions and displacement from operational arrays. Details of this process are provided in **Appendix 11.3** (**Volume III**).

158. CPGR and the CPS after 25 years of deployment are presented for guillemot and razorbill **Table 11-21** and **Table 11-22** respectively.

159. The use of avoidance rates of between 98 % and 99.9 % suggests that the guillemot population would continue to increase from present day levels if a 240 MW array consisting of the devices listed at **Chapter 4, Project Description** and **Appendix 11.3** (**Volume III**) was deployed and operated for 25 years. At the lowest avoidance rate (95 %), at 25 years under these conditions, the model predicts an overall guillemot population of <10 % of when compared with unimpacted conditions predicted after 25 years, and also when compared to the population at the latest colony count. At 98 % avoidance, the population after 25 years would be 40.5 % of what is predicted under unimpacted conditions, which would be slightly less birds than were present at the latest colony count. Avoidance rates of 99 % or higher result in a population of at least 69.2 % the size of the predicted baseline population, and up to 95.6 % in the case of a 99.9 % avoidance rate.

Table 11-21 CPGR and CPS (25 year) Metrics for PVA for South Stack and Penlas SMP Sub-Colonies for Guillemot During the Breeding Season, 240 MW Deployment

Avoidance Rate	Growth Rate	Population After 25 Years (total individual breeding adults)	Counterfactual of Growth Rate	Counterfactual of 25 Year Population	25 Year Population Relative to Current Population
Baseline	1.037	18,353	N/A	N/A	2.461
95 %	0.911	438	0.893	0.024	0.059
98 %	1.004	7,437	1.000	0.405	0.996
99 %	1.023	12,691	1.021	0.692	1.700
99.5 %	1.031	15,461	1.030	0.842	2.071
99.9 %	1.035	17,539	1.035	0.956	2.350

160. The guillemot population of the South Stack and Penlas SMP sub-colonies has been increasing since at least the early 1980's, but there is some evidence based on more recent counts that the population is unlikely to continue to grow indefinitely at the rate seen between the 1980's and the present day (JNCC, 2018). Whilst the reason for this is unclear, if colony growth is constrained in the medium term in its baseline state (i.e. in the absence of the Project), then it is possible that the differences between the different impact scenarios considered in the assessment and the predicted baseline may be smaller in reality than suggested by the PVA,

though as stated above, CPGR and CPS are still useful indicators despite this. In addition, this model is considered precautionary because the starting population of 7,457 was that according to the latest SMP count (5,565) (**Table 11-16**) multiplied by an appropriate k-value (1.34) (Harris et al., 2015). Had the more recent RSPB count been available when the model had been run, the starting population would have been 12,984 (i.e. 9,690 x 1.34) (**Table 11-16**). This population is approximately 75 % larger than the starting population used by the PVA. The larger starting population would result in a population which may possess greater resilience with respect to additional mortality.

161. At an avoidance rate of 95 %, it is predicted that deployment of a 240 MW array consisting of the devices listed at **Chapter 4, Project Description** would result in the extinction of the razorbill population within the South Stack and Penlas SMP master site after several years of operation, with a similar outcome in terms of population level predicted at 98 % avoidance. At an avoidance rate of 99 %, the population after 25 years of deployment would be 33.6 % of that predicted under unimpacted conditions, which is less birds than were recorded at the latest colony count. The use of avoidance rates of 99.5 % and 99.9 % results in increases in populations from the last colony count after 25 years of deployment, but 69.1 % and 92.9 % of what would be expected under unimpacted conditions.

Table 11-22 CPGR and CPS (25 year) Metrics for PVA for South Stack and Penlas SMP Sub-Colonies for Razorbill During the Breeding Season, 240 MW Deployment

Avoidance Rate	Growth Rate	Population After 25 Years (total individual breeding adults)	Counterfactual of Growth Rate	Counterfactual of 25 Year Population	25 Year Population Relative to Current Population
Baseline	1.037	3,430	N/A	N/A	2.338
95 %	0.233	0	0.226	0.000	0.000
98 %	0.889	77	0.859	0.022	0.052
99 %	0.990	1,152	0.957	0.336	0.785
99.5 %	1.019	2,371	0.985	0.691	1.616
99.9 %	1.032	3,186	0.997	0.929	2.172

162. Like guillemot, the razorbill population at the South Stack and Penlas SMP sub-colonies has been increasing since at least the early 1980's, but there is some evidence based on more recent counts that the population is unlikely to continue to grow at the rate seen between the 1980's and the present day indefinitely (JNCC, 2018). Whilst the reason for this is unclear, if colony growth is constrained in the medium term in its baseline state (i.e. in the absence of the Project), then it is possible that the differences between the different impact scenarios considered in the assessment and the predicted baseline may be smaller in reality than suggested by the PVA, though as stated above, CPGR and CPS are still useful indicators despite this. As with guillemot, the latest counts from the RSPB suggest a larger starting population (1,790) than the 1,467 derived from SMP data (**Table 11-16**). This population is approximately 34 % larger than the starting population used by the PVA. The larger starting population would result in a population which may possess greater resilience with respect to additional mortality.

163. The following magnitudes of impact due to collision at a 240 MW deployment scale are considered appropriate, based on expert opinion, considering the wider backdrop of an increasing auk population in Wales (**Section 11.5.6)**, and assuming that 95 % avoidance rates are used on a precautionary basis:

- **Very high negative** for guillemot (breeding), razorbill (breeding), and the South Stack and Penlas SMP sub-colonies;
- **Medium negative** for guillemot (non-breeding) and razorbill (non-breeding);
- **Low negative** for, puffin (breeding) and red-throated diver (non-breeding); and
- **Negligible** for gannet (breeding), Manx shearwater (breeding), shag (breeding) and cormorant (presumed), as well as all non-diving marine ornithology receptors.

164. Whilst the above magnitudes of impact are used by the assessment for precautionary reasons, a change to 99 % avoidance rate would result in the following magnitudes of impact being assigned:

- **High negative** for razorbill (breeding), and the South Stack and Penlas SMP sub-colonies;
- **Medium negative** for guillemot (breeding); and
- **Negligible** for gannet (breeding), guillemot (non-breeding), Manx shearwater (breeding), puffin (breeding), razorbill (non-breeding) and red-throated diver (non-breeding) shag (breeding) and cormorant (presumed), as well as all non-diving marine ornithology receptors (**Table 11-11**).

11.6.6.3.3.2. 40 MW Worst Case Scenario

165. A 40 MW worst case scenario has been considered in order to reflect the expected scale of a first commercial level phase of deployment within the Project. Several tidal device parameter envelopes, identified by alphanumeric codes, have been considered, each representing a realistic worst case for that particular type of device (**Appendix 11.3, Volume III**). The impact of different device envelopes varies considerably between species, depending largely on whether they are deep or shallow diving birds; the allocation of species to a particular definition is described in **Appendix 11.3** (**Volume III**). For a 40 MW single device initial phase of deployment for the Project (which is a level of deployment considered appropriate to assess for all devices except for 2F and 9F, and therefore these devices are excluded), the annual number of collisions for each species by time period (breeding and non-breeding seasons (**Table 11-9**), for the device envelope that resulted in the most collisions for that species, is presented in **Table 11-23**. It should be noted that this represents a worst case and other devices resulted in less collisions, details of which are presented in **Appendix 11.3** (**Volume III**).

Table 11-23 Number of Predicted Collisions in a Single Season (Mean of ERM and CRM) for Diving Species Recorded in MDZ by Appropriate Time Period, at a Range of Different Avoidance Rates, for a Worst-Case Device Envelope Scenario at a Deployment Scale of 40 MW

Species	Time Period (B/NB)	Device	Avoidance Rate (%)							
			0	50	90	95	98	99	99.5	99.9
Gannet	B	1F/3F	2	1	0	0	0	0	0	0
Guillemot	B	4F	4,952	2,476	495	248	99	50	25	5

Species	Time Period (B/NB)	Device	Avoidance Rate (%)							
			0	50	90	95	98	99	99.5	99.9
	NB		1,063	531	106	53	21	11	5	1
Manx shearwater	B	1F	35	17	3	2	1	0	0	0
Puffin	B	3F	22	11	2	1	0	0	0	0
Razorbill	B	3F	1,517	758	152	76	30	15	8	2
	NB		1,513	757	151	76	30	15	8	2
Red-throated diver	NB	3F	151	76	15	8	3	2	1	0
Shag	B	4F/6S	4	2	0	0	0	0	0	0

166. To examine the significance of the values in **Table 11-23** in the context of relevant populations of each species, the predicted number of collisions in a season was compared to the probable reference population (the BDMPS or population of colonies in **Table 11-11**). On the basis of information regarding the likely components of an avoidance rate and the precautionary values input into the models (**Section 11.6.6.3.2** and **Appendix 11.3, Volume III**), the assessment focuses on avoidance rates between 95 % and 99.9 % (**Table 11-24**).

Table 11-24 Collision Rates at 95 to 99.9 % Avoidance Rates (Mean of ERM and CRM) Relative to Relevant Reference Populations, for a Worst-Case Device Envelope Scenario at a Deployment Scale of 40 MW, in a Single Season

Species	Time Period (B/NB)	Reference Population (individual birds) (Table 11-11)	Probable Number of Collisions per Season	As % of Reference Population
Gannet	B	138,474	0	0
Guillemot	B	7,457	5 - 248	0.07 - 3.33
	NB	1,139,220	1 - 53	0.0001 - 0.005
Manx shearwater	B	673,350	0 - 2	0 - 0.0003
Puffin	B	1,746	0 - 1	0 - 0.06
Razorbill	B	1,467	2 - 76	0.14 - 5.18
	NB	341,422 (Nov-Dec) 606,914 (Aug-Oct and Jan-Mar)	2 - 76	0 - 0.02 (max)
Red-throated diver	NB	1,676	0 - 8	0 - 0.48
Shag	B	26	0	0

167. It is recognised that the behaviour of non-breeding guillemot is dispersive rather than migratory (Furness, 2015). This means that because the MDZ is situated in close proximity to breeding colonies for these species within the South Stack and Penlas SMP sub-colonies, the proportion of non-breeding birds present in and around the MDZ that are from these colonies may be higher than suggested in Furness (2015). Depending on the proportion of guillemots in the MDZ from the South Stack and Penlas SMP sub-colonies versus the wider UK Western Waters BDMPS during the non-breeding season, the upper limit of non-breeding season collisions of 53 birds (at 95 % avoidance) could represent between 0 % to 0.8 % of the South Stack and Penlas SMP sub-colonies breeding adult population, depending on the dispersal rate of birds from this colony following the breeding season. The upper, worst case value of 0.8 % is only applicable if no guillemots disperse from the colony during the non-breeding season and all collisions are birds

from this colony, which is implausible. This calculation is highly precautionary as it does not include the non-breeding component of the population in the overall population size.

168. Due to the potentially high number of collisions predicted for guillemot and razorbill, in addition to the understanding that 100 % of the MDZ population originates from the same SMP master colony, a PVA was carried out on the population of the South Stack and Penlas SMP sub-colonies for both species during the breeding season (encompassing the Gogarth, South Stack and Abraham's Bosom sub-colonies), using the same avoidance rates presented above. PVAs considered the combined predicted effects of mortality from collisions and displacement from operational arrays and due to construction and operational / repowering vessel traffic. Details of this process are provided in **Appendix 11.3** (**Volume III**).

169. Counterfactual of Population Growth Rates (CPGR) and the Counterfactual of Population Size (CPS) after 25 years of deployment are presented for guillemot and razorbill in **Table 11-25** and **Table 11-26** respectively. Whilst this is shorter than the operational lifespan of 37 years, no array will be deployed continuously for this length of time. CPGR is the ratio of the predicted population annual growth rate with and without the Project impacts, and CPS is the ratio of the predicted end-point population size with and without the Project impacts at 25 years of operation. These metrics have been demonstrated to have low sensitivity to the mis-specification of input parameters (e.g. demographic rates) and to the underlying assumptions of the population models from which the PVAs are derived (Cook and Robinson, 2016; Jitlal et al., 2017).

170. The use of avoidance rates of between 95 % and 99.9 % suggests that the guillemot population of the South Stack and Penlas SMP sub-colonies would continue to grow (population growth rate >1) compared to the latest colony count if a 40 MW array consisting of devices which cause the largest impact on this species was deployed and operated for 25 years. At the lowest avoidance rate (95 %), after 25 years under these conditions, the PVA predicts an overall guillemot population of 63.7 % when compared with the predicted unimpacted conditions after 25 years. Avoidance rates of 98 % or higher result in a population of at least 85.1 % the size of the predicted unimpacted population, or above.

Table 11-25 CPGR and CPS (25 year) Metrics for PVA for South Stack and Penlas SMP Sub-Colonies for Guillemot During the Breeding Season, 40 MW Worst-Case Deployment

Avoidance Rate	Growth Rate	Population After 25 Years (total individual breeding adults)	Counterfactual of Growth Rate	Counterfactual of 25 Year Population	25 Year Population Relative to Current Population
Baseline	1.037	18,353	N/A	N/A	2.461
95 %	1.018	11,686	0.982	0.637	1.566
98 %	1.030	15,615	0.994	0.851	2.092
99 %	1.033	16,485	0.997	0.918	2.209
99.5 %	1.035	17,445	0.998	0.951	2.337
99.9 %	1.036	17,909	0.999	0.976	2.399

171. The guillemot population of the South Stack and Penlas SMP sub-colonies has been increasing since at least the early 1980's, but there is some evidence based on more recent counts that

the population is unlikely to continue to grow indefinitely at the rate seen between the 1980's and the present day (JNCC, 2018). Whilst the reason for this is unclear, if colony growth is constrained in the medium term in its baseline state (i.e. in the absence of the Project), then it is possible that the differences between the different impact scenarios considered in the assessment and the predicted baseline may be smaller in reality than suggested by the PVA, though as stated above, CPGR and CPS are still useful indicators despite this. In addition, this model is considered precautionary because the starting population of 7,457 was that according to the latest SMP count (5,565) (**Table 11-16**) multiplied by an appropriate k-value (1.34) (Harris et al., 2015). Had the more recent RSPB count been available when the model had been run, the starting population would have been 12,984 (i.e. 9,690 x 1.34) (**Table 11-16**). This population is approximately 75 % larger than the starting population used by the PVA. The larger starting population would result in a population which may possess greater resilience with respect to additional mortality.

172. Regarding the PVA for razorbill, the use of avoidance rates of between 98 % and 99.9 % suggests that the population would continue to grow compared to the latest colony count if a 40 MW array consisting of devices which cause the largest impact on this species was deployed and operated for 25 years. At the lowest assessed avoidance rate (95 %), after 25 years under these conditions, the PVA predicts an overall razorbill population of 24.1 % when compared with the predicted unimpacted conditions after 25 years, or 56.4 % of the population at the latest colony count. Avoidance rates of 99 % or higher result in a population of at least 86.1 % the size of the predicted baseline population, or above, whilst at an avoidance rate of 98 %, the population is expected to be 71.3 % of the baseline prediction after 25 years of Project operation.

Table 11-26 CPGR and CPS (25 year) Metrics for South Stack and Penlas SMP Sub-Colonies for Razorbill During the Breeding Season, 40 MW Worst-Case Deployment

Avoidance Rate	Growth Rate	Population After 25 Years (total individual breeding adults)	Counterfactual of Growth Rate	Counterfactual of 25 Year Population	25 Year Population Relative to Current Population
Baseline	1.035	3,430	N/A	N/A	2.338
95 %	0.977	827	0.945	0.241	0.564
98 %	1.021	2,446	0.987	0.713	1.667
99 %	1.028	2,953	0.994	0.861	2.013
99.5 %	1.031	3,140	0.996	0.915	2.140
99.9 %	1.033	3,266	0.998	0.952	2.226

173. Like guillemot, the razorbill population at the South Stack and Penlas SMP sub-colonies has been increasing since at least the early 1980's, but there is some evidence based on more recent counts that the population is unlikely to continue to grow indefinitely at the rate seen between the 1980's and the present day (JNCC, 2018). Whilst the reason for this is unclear, if colony growth is constrained in the medium term in its baseline state (i.e. in the absence of the Project), then it is possible that the differences between the different impact scenarios considered in the assessment and the predicted baseline may be smaller in reality than suggested by the PVA, though as stated above, CPGR and CPS are still useful indicators despite this. As with guillemot, the latest counts from the RSPB suggest a larger starting

population (1,790) than the 1,467 derived from SMP data (**Table 11-16**). This population is approximately 34 % larger than the starting population used by the PVA. The larger starting population would result in a population which may possess greater resilience with respect to additional mortality.

174. The following precautionary magnitudes of impact due to collision at a 40 MW deployment scale are considered appropriate, based on expert opinion, considering the wider backdrop of an increasing auk population in Wales (**Section 11.5.6)**, and assuming that 95 % avoidance rates are used on a precautionary basis:

- **High negative** for razorbill (breeding), and the South Stack and Penlas SMP sub-colonies;
- **Medium negative** for guillemot (breeding);
- **Low negative** for guillemot (non-breeding), razorbill (non-breeding) and red-throated diver non-breeding, year round); and
- **Negligible** for gannet (breeding), Manx shearwater (breeding), puffin (breeding) and shag (breeding), as well as cormorant (presumed), and all non-diving marine ornithology receptors (**Table 11-11**).

175. Whilst the above magnitudes of impact are used by the assessment for precautionary reasons, a change to 99 % avoidance rate would result in the following magnitudes of impact being assigned:

- **Low negative** for guillemot (breeding), razorbill (breeding), and the South Stack and Penlas SMP sub-colonies; and
- **Negligible** for gannet (breeding), guillemot (non-breeding), Manx shearwater (breeding), puffin (breeding), razorbill (non-breeding) and red-throated diver (non-breeding) and shag (breeding), as well as cormorant (presumed), and all non-diving marine ornithology receptors (**Table 11-11**).

11.6.6.3.4. Impact Significance

11.6.6.3.4.1. 240 MW Full Deployment Scenario

176. The impact significance for marine ornithology receptors for this impact, assuming a 95 % avoidance rate, which has been selected due to uncertainty in whether a higher avoidance rate is applicable, is as follows:

- **Major adverse** for guillemot (breeding), razorbill (breeding) and the South Stack and Penlas SMP sub-colonies;
- **Moderate adverse** for guillemot (non-breeding) and razorbill (non-breeding);
- **Minor adverse** for gannet (breeding), guillemot (non-breeding), Manx shearwater (breeding), puffin (breeding), razorbill (non-breeding), red-throated diver (non-breeding) and shag (breeding); and
- **Negligible** for all non-diving marine ornithology receptors.

11.6.6.3.4.2. 40 MW Worst Case Scenario

177. The impact significance for marine ornithology receptors for this impact, assuming a 95 % avoidance rate, which has been selected due to uncertainty in whether a higher avoidance rate is applicable, is as follows:

- **Major adverse** for razorbill (breeding) and the South Stack and Penlas SMP sub-colonies;
- **Moderate adverse** for guillemot (breeding);
- **Minor adverse** for gannet (breeding), guillemot (non-breeding), Manx shearwater (breeding), puffin (breeding), razorbill (non-breeding), red-throated diver (non-breeding) and shag (breeding); and
- **Negligible** for all non-diving marine ornithology receptors.

11.6.6.3.5. Mitigation and Residual Impact

11.6.6.3.5.1. 240 MW Full Deployment Scenario

178. To enable the consent of a maximum deployment of 240 MW of tidal devices as described in **Chapter 4, Project Description,** surveillance of key receptors supported by empirical information is required to give confidence that no significant impacts are occurring. An important aim will be refinement of CRM / ERM models to allow demonstration that predicted collisions are at a level that would not result in an ecologically significant adverse effect on razorbill and guillemot (e.g. demonstrating avoidance rates of at least 99.5 % for breeding guillemot, and 99.9 % for breeding razorbill).

179. A phased approach to deployment will allow collection of surveillance and empirical data required to give confidence that no significant adverse effects are apparent and refine estimates of avoidance rates and other parameters of the ERM and CRM models. As the key adverse impacts which constrain deployment would be on guillemot and razorbill breeding at the South Stack and Penlas SMP sub-colonies, these colonies would be the focus of attention. A monitoring strategy, developed as part of an Environmental Mitigation and Monitoring Plan (EMMP) would include three principal aims; monitoring bird use of the MDZ area and in particular in the vicinity of TECs (e.g. coastal vantage point watches, boat or aerial surveys), monitoring seabird colonies with connectivity to the Project (recording numbers, breeding success and survival rates), and recording the behaviour of birds in the immediate vicinity of TECs (e.g. through underwater sonar/video devices attached to TECs) and/or (if possible due to practical issues such as the ability to safely access colonies for bird capture and tag deployment) deployment of tags recording locations and diving behaviour of guillemots and razorbills from the South Stack and Penlas SMP sub-colonies. The EMMP when developed, would also include mitigation and monitoring plans for marine mammal receptors, with further details discussed in **Chapter 12, Marine Mammals.**

180. The general goals of the monitoring strategy would be to provide finer scale information on distribution, densities, diving depths and bird behaviour in the vicinity of TECs, throughout the day and night, refine the accuracy of / reduce uncertainty in input parameters and avoidance rates for ERM/CRM.

181. This monitoring work would be undertaken in conjunction with SNCBs under appropriate licensing arrangements.

182. Further information on the proposed monitoring is described in **Document MOR/RHDHV/DOC/0072, Outline Environment Mitigation and Monitoring Plan**.

183. The EMMP will aim to demonstrate refinement of CRM / ERM models and use other methods and approached such as design of array location and layout to reduce risk, such that the predicted collisions are at a level that would not result in an ecologically significant adverse effect on razorbill and guillemot (e.g. setting of avoidance to at least 99.5 % for breeding guillemot, and 99.9 % for breeding razorbill), the magnitude of impact could be revised to "low adverse" for both species, as well as the South Stack and Penlas SMP sub-colonies. This would result in a residual impact significance of **Minor adverse** for all three receptors.

11.6.6.3.5.2. 40 MW Worst Case Scenario

184. To enable the consent of an initial 40 MW commercial deployment of tidal devices, it may be necessary to collect data and maintain surveillance of receptor groups in order to increase confidence in the assessments undertaken. For example, the collection of further empirical information may allow refinement of CRM / ERM models such that the predicted collisions can be demonstrated to be at a level that would not result in an ecologically significant adverse effect on razorbill and guillemot (e.g. demonstrating avoidance rates of at least 98 % or greater for guillemot, and 99 % or greater for razorbill).

185. The intention of the Project is to install a first commercial phase of development at around 40 MW, as detailed in **Chapter 25, Socio-economics, Tourism and Recreation**. To build out to that scale and beyond to 240 MW will require several years, and within that timeframe the establishment of monitoring and mitigation measures through an Environmental Mitigation and Management Plan (EMMP) is proposed. The EMMP would also support mitigation and management requirements identified within **Chapter 12, Marine Mammals**. Before the first deployment and between subsequent deployments, detailed information on the behaviour of guillemot and razorbill breeding at the South Stack and Penlas SMP sub-colonies will be collected using three principal methods; coastal vantage point watches, colony counts, and a dual deployment of bird-borne time-depth-temperature recorders and GPS recorders on as large a sample size of the South Stack and Penlas SMP sub-colonies population as is permitted (and is possible due to practical issues such as the ability to safely access colonies for bird capture and tag deployment). Other methods such as boat-based surveys will be considered.

186. The general goals of the tagging would be to provide finer scale distribution information and densities to feed into refined ERM/CRM, and the production of depth distributions for diving guillemot and razorbill, which would also feed into refined ERM/CRM. Finally, information enabling more accurate modelling of nocturnal diving behaviour, and the risk that birds undertaking these behaviours are subject to with regard to collision with tidal devices.

187. This monitoring work would be undertaken in conjunction with SNCBs under appropriate licensing arrangements. Other methods (for example the use of sonar data for diving birds) will be considered for inclusion in the monitoring programme where their deployment could provide useful information.

188. Further information on the proposed monitoring is described in **Document MOR/RHDHV/DOC/0072, Outline Environment Mitigation and Monitoring Plan**.

189. Should the proposed monitoring work be successful in justifying the setting of avoidance rates to the required levels, the magnitude of impact could be revised to "low negative" for both species, as well as the South Stack and Penlas SMP sub-colonies. This would result in a residual impact significance of **Minor adverse** for all three receptors.

11.6.6.4. Entanglement with Tidal devices

11.6.6.4.1. Introduction

190. The operational / repowering phase of the Project has the potential to affect bird populations in the marine environment through birds becoming entangled in tidal devices, resulting in mortality through drowning or possible injury. This could occur at considerable depth, or nearer the surface in the case of moorings of floating or surface emergent tidal devices.

191. Any impacts resulting from this impact pathway would be spatially restricted to subtidal areas adjacent to devices, and temporally restricted to the duration of operation (up to 35 years; long term). A maximum of 130 surface emergent devices may be deployed in total.

11.6.6.4.2. Receptor Sensitivity

192. The sensitivity of each of the marine ornithology receptors to entanglement has been assessed using the classification of species in Furness et al. (2012) according to their apparent drowning risk. A score of one was defined as extremely low risk, whilst a score of five was defined as moderate risk. These classifications have been used to screen out species not considered susceptible to this impact pathway (**Table 11-27**).

Table 11-27 Screening Exercise Undertaken for Potential Entanglement Impacts During the Operation / Repowering of the Project

Species	Drowning Risk[1]	Screening Result (In or Out)	Justification
Arctic tern	1	Out	Low susceptibility to drowning
Black-headed gull	1	Out	Low susceptibility to drowning
Common gull	1	Out	Low susceptibility to drowning
Common scoter	4	Out	Only recorded occasionally (5/24 surveys), always in flight, and usually in coastal locations
Common tern	1	Out	Low susceptibility to drowning
Cormorant	4	In	Only recorded occasionally (2/24 surveys) in very low numbers, always in flight, but screened in as attraction into MDZ possible due to provision of roosting platforms by tidal devices
Eider	4	Out	Recorded on only one baseline survey
Fulmar	1	Out	Low susceptibility to drowning
Gannet	2	Out	Low susceptibility to drowning
Great black-backed gull	1	Out	Low susceptibility to drowning
Guillemot	4	In	Potentially susceptible to drowning and abundant in MDZ; screened in

Species	Drowning Risk[1]	Screening Result (In or Out)	Justification
Herring gull	1	Out	Low susceptibility to drowning
Kittiwake	1	Out	Low susceptibility to drowning
Lesser black-backed gull	1	Out	Low susceptibility to drowning
Manx shearwater	1	Out	Low susceptibility to drowning
Mediterranean gull	1	Out	Low susceptibility to drowning
Puffin	3	In	Potentially susceptible to drowning and abundant in MDZ; screened in
Razorbill	4	In	Potentially susceptible to drowning and relatively abundant in MDZ; screened in
Red-throated diver	4	In	Recorded infrequently (8/24 surveys) and in low numbers but screened in on a precautionary basis due to sensitivity to impact
Sandwich tern	1	Out	Low susceptibility to drowning
Shag	4	In	Recorded infrequently (8/24 surveys) and in low numbers, but screened in as attraction into MDZ possible due to provision of roosting platforms by tidal devices
Notes [1]Furness et al., (2012)			

193. Whilst the risk of drowning is less than moderate for all marine ornithology receptors according to Furness et al., (2012), there is potential for entanglement impacts on cormorant, guillemot, puffin, razorbill, red-throated diver and shag. The conclusions of the screening assessment are supported by a review of literature relating to bycatch of seabirds (Žydelis et al., 2013, 2009).

194. The following sensitivities to this impact pathway have been allocated according to the definitions in **Chapter 5, EIA Methodology**:

- **Medium** for cormorant, guillemot, puffin, razorbill, red-throated diver and shag; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.6.4.3. Magnitude of Impact

195. Any impacts resulting from this impact pathway will be spatially restricted to the areas occupied by the tidal devices themselves, and temporally restricted to the duration of their operation (i.e. long term). The consequence of entanglement is likely to be a fatality of the bird involved and a consequent permanent reduction in the relevant population.

196. Whilst seabird bycatch in gill nets is known to be a major issue for seabird populations (Žydelis et al., 2013, 2009), the design of a tidal energy converter means that they pose a much lower risk to seabirds with respect to entanglement and drowning. There are no loose cables or lines associated with the devices, and anchor chains and cables are substantial and not light enough to loop or coil. The structures themselves are designed to be hydrodynamic, and not offer surfaces for entanglement.

197. On the basis of the available information, the magnitude of impact is therefore considered to be:

- **Low negative** for cormorant, guillemot, puffin, razorbill, red-throated diver and shag; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.6.4.4. Impact Significance

198. The impact significance for marine ornithology receptors for this impact is as follows:

- **Minor adverse** for cormorant, guillemot, puffin, razorbill, red-throated diver and shag; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.6.5. Other Impacts

11.6.6.5.1. Introduction

199. Indirect impacts on marine ornithology receptors may occur during the operational / repowering phase if there are impacts on prey species and the habitats of prey species. These include those resulting from the production of underwater noise and the generation of suspended sediments that may alter the behaviour or availability of prey species for seabirds. There is also the possibility of pollution incidents due to ejection of contaminants or accidents involving tidal devices, and/or vessels. As well as resulting in potential indirect effects on seabirds, direct impacts due to direct contact with contaminants is possible and is also covered in this section.

11.6.6.5.2. Receptor Sensitivity

200. Underwater noise may cause fish and mobile invertebrates to avoid the construction area and its immediate surroundings, and also affect their physiology and behaviour. Suspended sediments may cause fish and mobile invertebrates to avoid the construction area and its immediate surroundings and may smother and hide immobile benthic prey in a localised area. These mechanisms may result in less prey being available within the MDZ and immediate surrounding area to foraging seabirds. Pollution events may cause localised injury or mortality to seabirds or their prey species in the immediate vicinity of the source of the pollution.

201. Generally speaking, seabirds are mobile animals. In the breeding season they adopt a central place foraging strategy, restricting their foraging areas to enable them to successfully provision their chicks. In the non-breeding season, birds may be sedentary, remaining in the area where they bred, dispersive, or fully migratory. The mobility of seabirds means that they are able to utilise alternative areas of habitat should an area of habitat within their range become unavailable. Habitat flexibility is also an important criterion in determining the ability of a particular species to find alternative foraging habitat, and whilst a qualitative measure, it has been reviewed by several sources (Furness et al., 2012; Furness and Wade, 2012; Garthe and Hüppop, 2004).

202. The sensitivities of ornithological receptors for these impacts during construction, presented in **Table 11-18** remain relevant for the operational / repowering phase of the Project. This means that Arctic tern, common tern, common scoter, cormorant, eider, guillemot, puffin, razorbill, red-throated diver, Sandwich tern and shag are considered to have “low” sensitivity, and black-headed gull, common gull, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater and Mediterranean gull a **Negligible** sensitivity.

11.6.6.5.3. Magnitude of Impact

203. With regard to noise impacts, **Chapter 10, Fish and Shellfish Ecology** and **Chapter 14, Commercial Fisheries** discuss the potential impacts upon fish relevant to marine ornithology as prey species. For species such as herring, sprat and sandeel, which are prey items of several seabirds that are being assessed in this EcIA, the impact magnitude of underwater noise effects (physical injury or behavioural changes) and habitat loss during operation / repowering is considered to be minor or negligible. With regard to the definitions of impact magnitude given in **Chapter 5, EIA Methodology**, it is concluded that the magnitude of impact on seabirds occurring in or around the Project during the operational phase is **Negligible**. This applies to direct effects on seabirds themselves, and their prey.

204. With regard to changes to the seabed and to suspended sediment levels, **Chapter 7, Metocean Conditions and Coastal Processes** and **Chapter 9, Benthic and Intertidal Ecology** discuss the nature of any change and impacts on the seabed and benthic habitats, which host seabird prey species. The maximum envisaged effect associated with sediment plumes arising from the construction phase will cause only very minor increases in suspended sediment concentration; typically less than 1 mg/l a short distance from the release point, over a distance of several hundred metres. During the operational / repowering phase the same value has been assumed, which is considered to be a highly precautionary approach. The effects will be temporary and fully reversible, with a return to very low background concentrations occurring rapidly upon cessation of installation activities. Other than at the immediate release point, such a change would be immeasurable. It is concluded that the magnitude of impact on seabirds occurring in or around the Project during the operational / repowering phase is **Negligible**.

205. Any pollution incidents, which are considered to be unlikely to occur, will result in the contamination of a small area (likely no more than several hundreds of metres) of subtidal habitat with a small amount of pollution. Measures will be in place to rapidly collect or disperse any such contamination, meaning that its presence will be temporary and reversible. Tidal devices contain very small amounts of potential pollutant in the form of lubricant. Based on the definitions of impact magnitude given in **Chapter 5, EIA Methodology**, the magnitude of impact is considered to be negligible.

11.6.6.5.4. Impact Significance

206. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Negligible** for Arctic tern, black-headed gull, common gull, common tern, common scoter, cormorant, eider, fulmar, gannet, great black-backed gull, guillemot, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull, puffin, razorbill, red-throated diver, Sandwich tern and shag.

11.6.7. Potential Impacts During Decommissioning

11.6.7.1. Introduction

207. Any effects generated during the decommissioning phase of the Project are expected to be similar to those generated during the construction phase (Section 11.6.5). This is because decommissioning is assumed involve a reverse of the construction phase through the removal of some structures and materials installed. The duration of the decommissioning phase is assumed to be similar to the construction.

208. It is anticipated that any future activities would be programmed in close consultation with the relevant statutory marine and nature conservation bodies, to allow any future guidance and best practice to be incorporated to minimise any potential impacts.

209. The following sections briefly summarise the predicted impact significance of the activities proposed during decommissioning and are identical to those expected during construction. Further background and detail is provided in **Section 11.6.5**.

11.6.7.2. Airborne Noise and Visual Disturbance

210. The impact significance for marine ornithology receptors for airborne noise and visual disturbance during decommissioning is as follows:

- **Minor adverse** for guillemot, puffin, razorbill, red-throated diver and shag; and
- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull and Sandwich tern.

11.6.7.3. Disturbance at Breeding Sites

211. The impact significance for marine ornithology receptors for disturbance at breeding sites during decommissioning is as follows:

- **Medium adverse** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating within 300 m from the colonies; and
- **Negligible** for the Abraham's Bosom, South Stack and Gogarth seabird colonies for vessels operating in excess of 300 m from the colonies.

212. Based on the species known to breed at each of the potentially affected colonies (**Table 11-16**), and excluding any species understood to possess a "low" sensitivity to disturbance and displacement when at sea (**Table 11-13**), it is considered that it is appropriate to prohibit all vessel activities within 300 m of each of these colonies during the breeding season. This is considered to be March to July for Abraham's Bosom and February to August for South Stack and Gogarth based on the species present at the last count (JNCC, 2018).

213. If this measure is adopted, then the receptor sensitivity can be reduced from "medium" to "low" as most of the individuals will not be present outside the breeding season. The magnitude of

impact can also be reduced from "medium" to "low" based on the definitions provided in **Chapter 5, EIA Methodology**. The residual impact significance is **Minor adverse**.

11.6.7.4. Other Impacts

214. On this basis, the impact significance for marine ornithology receptors for this impact is as follows:

- **Negligible** for Arctic tern, black-headed gull, common gull, common scoter, common tern, cormorant, eider, fulmar, gannet, great black-backed gull, guillemot, herring gull, kittiwake, lesser black-backed gull, Manx shearwater, Mediterranean gull, puffin, razorbill, red-throated diver, Sandwich tern and shag.

11.6.8. Cumulative Impacts

11.6.8.1. Screening for Cumulative Impacts

215. The potential effects from the Project that were screened in for assessment for the Project alone were further screened for the potential for cumulative effects with other projects. This process is detailed in **Table 11-28**.

Table 11-28 Cumulative Impact Assessment Screening

Impact	Potential for Cumulative Impact	Confidence of Prediction[1]	Justification
Airborne noise and visual disturbance	Yes	High	The likelihood that there would be a cumulative impact is low because the impact as a result of the Project occurs on a small spatial scale and it is dependent on a spatial co-incidence of disturbance / displacement from other plans or projects. However, one such project has been identified, therefore a more detailed assessment will be carried out for construction and operational / repowering impacts.
Disturbance at breeding sites	No	High	The likelihood that there would be a cumulative impact is low because it would be dependent on a spatial co-incidence of disturbance / displacement from other plans or projects during either construction or operation / repowering of the Project, of which none have been identified.
Collision risk with tidal devices	Yes	High	There is a sufficient likelihood of a cumulative impact to justify a quantitative cumulative impact assessment during the operational / repowering period of the Project. Cumulative impact due to collision risk from offshore wind farms has been screened out, as the collision risk to species as a result of the project that are also susceptible to collision with wind turbines (i.e. gannet) is very low (<3 birds per year under all deployment scenarios). All other species assessed as being at risk of collision during the

Impact	Potential for Cumulative Impact	Confidence of Prediction[1]	Justification
			operation / repowering of the Project are known not to be susceptible to collision with wind turbines.
Entanglement with tidal devices	No	High	The likelihood that there would be a cumulative impact is low because the impact as a result of the project is small in scale and magnitude, especially when compared to the wider issue of seabird bycatch.
Other impacts	No	High	The likelihood that there would be a cumulative impact is low because the impact as a result of the Project occurs on a small spatial scale and it is dependent on a temporal and spatial co-incidence of similar impacts from other plans or projects, of which none have been identified or are considered likely.
Notes [1]Indicates the degree of confidence; medium / low reflects lower confidence in older assessments which used variable methods.			

216. Two potential effects, airborne noise and visual disturbance, and collision risk (excluding offshore wind farms), were screened in for cumulative assessment.

11.6.8.2. Projects Considered for Cumulative Impacts

217. The classes of projects that could potentially be considered for the cumulative assessment of marine ornithology receptors include offshore wind farms, other marine renewable energy projects, marine aggregate extraction, oil and gas exploration and extraction, port and harbour projects, subsea cables and pipelines and commercial shipping. The identification of projects to include in the cumulative assessment of offshore ornithological receptors has been based on approved plans, constructed projects, approved but as yet unconstructed projects, projects for which an application has been made, is currently under consideration and may be consented. In addition, other “foreseeable” projects are included: those for which an application has not been made but have been the subject of consultation by the developer, or those are listed in plans that have clear delivery mechanisms. For such projects, the absence of robust or relevant data could preclude a quantitative cumulative assessment being carried out.

218. For airborne noise and visual disturbance, only projects occurring locally that involve activities in subtidal habitat are considered to have the potential to cause cumulative impacts in conjunction with the Project (**Table 11-29**). Any projects which have been ongoing since the collection of baseline data (e.g. Holyhead Harbour Maintenance Dredging) are not considered on the basis that they form part of the baseline.

219. Only other marine energy projects (i.e. those with contributions to underwater collision risk) are considered to have potential to contribute to cumulative collision risk (**Table 11-30**). Cumulative impact due to collision risk from offshore wind farms has been screened out, as the collision risk to species as a result of the Project that are also susceptible to collision with wind turbines (i.e. gannet) is very low (approximately zero to three birds per year based on a 240 MW deployment), and the reference population very large (**Section 11.6.6.3**). All other species assessed as being at risk of collision during the operation / repowering of the Project are known to not be

particularly susceptible to collision with wind turbines during flight (Dierschke et al., 2016), due mainly to the low flight heights they favour at sea (Furness et al., 2013; Garthe and Hüppop, 2004).

Table 11-29 Summary of Projects Considered in CIA for Airborne Noise and Visual Disturbance Impact Pathway

Project	Status	Distance from Nearest Part of Project (km)	Data Status	Justification for Inclusion
Holyhead Deep Phase I	In April 2017, a Marine Licence was granted for the first 0.5 MW installation	2	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline
Holyhead Deep Phase II	Scoping Report submitted in 2017; EIA presumed to be in preparation	2	No information available	Possible project that does not yet form part of the baseline
Holyhead Port Expansion	Scoping Report submitted 28/04/17; EIA in preparation	2	Draft, unpublished assessment available	Possible project that does not yet form part of the baseline

Table 11-30 Summary of Projects Considered in CIA for Underwater Collision Risk Impact Pathway

Project	Status	Distance from Nearest Part of Project (km)	Data Status	Justification for Inclusion
Holyhead Deep Phase I	In April 2017, a Marine Licence was granted for the first 0.5 MW installation	2	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline
Holyhead Deep Phase II	Scoping Report submitted in 2017; EIA presumed to be in preparation	2	No information available	Possible project that does not yet form part of the baseline
Bardsey Sound	An Agreement for Lease was awarded pre-May 2018. The project would include up to 20 100 kW turbines	50	None available	Possible project that does not yet form part of the baseline
Argyll Tidal Demonstration	Marine licence secured in 2015, status of works unknown	225	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline
Fair Head Marine Renewable Tidal Array	Environmental Statement presented. Target to be operational by 2021	228	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline
Sound of Islay Demonstration Site	Consented – construction programme not known	268	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline

Project	Status	Distance from Nearest Part of Project (km)	Data Status	Justification for Inclusion
West Islay Tidal Energy Farm	Consented – construction programme not known but scheduled for completion by 2022	268	Complete for marine ornithology receptors	Consented project that does not yet form part of the baseline

11.6.8.3. Cumulative Impact of Airborne Noise and Visual Disturbance

220. The assessment for the Project alone has identified a Minor adverse impact significance for guillemot due to airborne noise and visual disturbance during the construction and operation / repowering of the Project. Although between zero and approximately six guillemots could be lost due to this impact each year, this is not considered to represent a significant proportion of the local, regional or national population of this species.

221. The Environmental Statement for the “Holyhead Deep Phase I” project suggested that disturbance of guillemot to some extent is certain to occur during the construction and installation of the Project, but due to the relatively low numbers of birds present (<1 % of the regional breeding population), the impact was judged to be of negligible significance. The same conclusion was reached for the operational / repowering phase of the Project.

222. For the “Holyhead Deep Phase II” project, no information was available.

223. For the “Holyhead Port Expansion” project, no information was available.

224. As a result of these findings, the magnitude of this cumulative impact on guillemot (judged to be of **High** value and **Low** sensitivity) is considered to be **Negligible**, resulting in a **Negligible** cumulative impact significance.

11.6.8.4. Cumulative Impact of Collision Risk

11.6.8.4.1. Gannet

225. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for gannet (breeding) due to underwater collision.

226. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for gannet (breeding) due to underwater collision.

227. For the “Holyhead Deep Phase I”, “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects, the impact significance for gannet as a result of collision was defined as negligible.

228. For the “Holyhead Deep Phase II” project, no information was available.

229. For the “Bardsey Sound” project, no information was available.

230. As a result of these findings, the magnitude of this cumulative impact on gannet (judged to be of **High** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.2. Guillemot

231. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for guillemot (breeding and non-breeding) due to underwater collision subject to mitigation in the form of a deployment and monitoring strategy.

232. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for guillemot (breeding and non-breeding) due to underwater collision subject to mitigation in the form of a deployment and monitoring strategy.

233. For the “Holyhead Deep Phase I” project, it was considered that collisions of this species were likely to occur, and the impact significance was defined as negligible and not significant.

234. For the “Holyhead Deep Phase II” project, no information was available.

235. For the “Bardsey Sound” project, no information was available.

236. As the “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects are located well in excess of the known foraging range for this species (Cleasby et al., 2018; Oppel et al., 2018; Thaxter et al., 2012) at the South Stack and Penlas SMP subcolonies, cumulative impacts for these projects are not considered relevant to breeding guillemot. Whilst the impacts may be relevant to the non-breeding UK Western Waters BDMPS population, this is unlikely due to the size of that population and the scale of these developments.

237. As a result of these findings, the magnitude of this cumulative impact on guillemot (judged to be of **High** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.3. Manx Shearwater

238. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for Manx shearwater (breeding) due to underwater collision.

239. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for Manx shearwater (breeding) due to underwater collision.

240. For the “Holyhead Deep Phase I”, “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects, the impact significance for Manx shearwater as a result of collision was defined as negligible.

241. For the “Holyhead Deep Phase II” project, no information was available.

242. For the “Bardsey Sound” project, no information was available.

243. As a result of these findings, the magnitude of this cumulative impact on Manx shearwater (judged to be of **High** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.4. Puffin

244. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for puffin (breeding) due to underwater collision.

245. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for puffin (breeding) due to underwater collision.

246. For the “Holyhead Deep Phase I” project, the impact significance for puffin of collision was defined as negligible.

247. For the “Holyhead Deep Phase II” project, no information was available.

248. For the “Bardsey Sound” project, no information was available.

249. As the “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects are located well in excess of the known foraging range for this species, cumulative impacts for these projects are not considered relevant.

250. As a result of these findings, the magnitude of this cumulative impact on puffin (judged to be of **High** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.5. Razorbill

251. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for razorbill (breeding and non-breeding) due to underwater collision following mitigation.

252. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for razorbill (breeding and non-breeding) due to underwater collision following mitigation.

253. For the “Holyhead Deep Phase I” project, it was considered that collisions of this species were likely to occur, and the impact significance was defined as negligible and not significant.

254. For the “Holyhead Deep Phase II” project, no information was available.

255. For the “Bardsey Sound” project, no information was available.

256. As the “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects are located well in excess of the known foraging range for this species (Cleasby et al., 2018; Oppel et al., 2018; Thaxter et al., 2012), cumulative impacts for these projects are not considered relevant to breeding razorbill. However, the impacts may be relevant to the non-breeding UK Western Waters

BDMPS population. For all projects, the impact significance for razorbill of collision was defined as negligible .As the “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects are located well in excess of the known foraging range for this species (Cleasby et al., 2018; Oppel et al., 2018; Thaxter et al., 2012), cumulative impacts for these projects are not considered relevant to breeding razorbill. However, the impacts may be relevant to the non-breeding UK Western Waters BDMPS population. For all projects, the impact significance for razorbill of collision was defined as negligible.

257. As a result of these findings, the magnitude of this cumulative impact on razorbill (judged to be of **High** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.6. Red-Throated Diver

258. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for red-throated diver (non-breeding) due to underwater collision.

259. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for red-throated diver (non-breeding) due to underwater collision.

260. For the “Holyhead Deep Phase I”, “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects, the impact significance for red-throated diver as a result of collision is assumed to be negligible as it was generally not considered as being at risk of collision and therefore not assessed in detail.

261. For the “Holyhead Deep Phase II” and “Bardsey Sound” projects, no information was available.

262. As a result of these findings, the magnitude of this cumulative impact on red-throated diver (judged to be of **Medium** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.6.8.4.7. Shag

263. At the 40 MW initial deployment (worst case) scenario, the assessment for the Project alone has identified a Minor adverse impact significance for shag (breeding and non-breeding) due to underwater collision. Zero collisions per year were predicted assuming an avoidance rate of 95 % or greater.

264. At the 240 MW full deployment scenario, the assessment for the Project alone has identified a Minor adverse impact significance for shag (breeding and non-breeding) due to underwater collision. Between zero and one collisions per year were predicted assuming an avoidance rate of 95 % or greater.

265. For the “Holyhead Deep Phase I” project, this species was not assessed for collision risk. It is therefore assumed that the impact significance is negligible.

266. For the “Holyhead Deep Phase II” project, no information was available.

267. As the “Bardsey Sound”, “Argyll Tidal Demonstration”, “Fair Head Marine Renewable Tidal Array”, “Sound of Islay Demonstration Site” and “West Islay Tidal Energy Farm” projects are located well in excess of the known foraging range for this species (Cleasby et al., 2018; Oppel et al., 2018; Thaxter et al., 2012), and there is no spatial overlap of the relevant BDMPS (Furness, 2015), cumulative impacts for these projects are not considered relevant for this species.

268. As a result of these findings, the magnitude of this cumulative impact on shag (judged to be of **Medium** value and **Medium** sensitivity) is considered to be **Negligible**, resulting in a **Minor adverse** impact significance.

11.7. TRANSBOUNDARY IMPACTS

269. With regard to the potential for transboundary cumulative impacts, there is clearly potential for underwater collisions beyond UK territorial waters. However, any proposed marine energy development in Ireland is relatively small, and/or located on the west and north coasts. Since the spatial scale and hence seabird populations sizes for a transboundary assessment would be much larger, it is apparent that the scale of development expected would make no material difference to the assessment. For this reason, a quantitative assessment has not been carried out.

11.8. INTER-RELATIONSHIPS

270. The construction, operation / repowering and decommissioning phases of the Project would cause a range of effects on marine ornithology receptors. The magnitude of these effects has been assessed individually using expert knowledge and judgement, drawing from a wide scientific knowledge base that includes project-specific surveys and previously acquired knowledge of the bird ecology of the relevant geographical area (from published scientific papers and books, and ‘grey’ literature).

271. Impacts to marine ornithology receptors may be inter-related with other receptor groups. This is considered to be the case for impacts through effects on habitats and prey species only. For direct disturbance/displacement and collision risk there is considered to be no potential for interaction with other receptor groups.

272. Inter-relationships are summarised in **Table 11-31**, which indicates where assessments carried out in other chapters have been used to inform the offshore ornithology assessment.

Table 11-31 Inter-Topic Relationships

Impact	Related Chapter(s)	Relevant Section(s) in Chapter	Justification
Impacts on prey species and their habitats during construction	Chapter 7, Metocean and Coastal Processes Chapter 10, Fish and Shellfish Ecology	Section 11.6.5.3	Potential impacts on benthic ecology and fish and shellfish during construction could affect the prey
Impacts on prey species and their habitats during operation / repowering		Section 11.6.6.5	

Impact	Related Chapter(s)	Relevant Section(s) in Chapter	Justification
Impacts on prey species and their habitats during decommissioning	Chapter 14, Commercial Fisheries	Section 11.6.7.4	resource for marine ornithology receptors

11.9. INTERACTIONS

273. The impacts identified and assessed in this chapter have the potential to interact with each other, which could give rise to synergistic impacts. The worst case impacts assessed within the chapter take these interactions into account and therefore the impact assessments are considered conservative and robust. For clarity, the areas of interaction between impacts that have been classified as greater than negligible impact significance are presented in **Table 11-32** for construction and **Table 11-33** for operation / repowering. The potential for interactions of impacts anticipated during decommissioning are as per the construction impacts in **Table 11-32**.

Table 11-32 Potential for Interactions Between Impacts During Construction

	Airborne Noise and Visual Disturbance	Disturbance at Breeding Sites
Airborne Noise and Visual Disturbance	-	Unlikely, due to the use of appropriate vessel standoff zones around breeding colonies during the breeding season
Disturbance at Breeding Sites	Unlikely, due to the use of appropriate vessel standoff zones around breeding colonies during the breeding season	-

Table 11-33 Potential for Interactions Between Impacts During Operation / Repowering

	Airborne Noise and Visual Disturbance	Disturbance at Breeding Sites	Collision Risk with Tidal Devices	Entanglement with Tidal Devices
Airborne Noise and Visual Disturbance	-	Unlikely, due to the use of appropriate vessel standoff zones around breeding colonies during the breeding season	Possible interaction reflected by inclusion of mortality due to both pathways in PVA; possible attraction effects on shag and cormorant causing elevated collision risk than currently reported	No potential for significant synergistic effect
Disturbance at Breeding Sites	Unlikely, due to the use of appropriate vessel standoff zones around breeding colonies during the breeding season	-	No potential for significant synergistic effect	No potential for significant synergistic effect

	Airborne Noise and Visual Disturbance	Disturbance at Breeding Sites	Collision Risk with Tidal Devices	Entanglement with Tidal Devices
Collision Risk with Tidal Devices	Possible interaction reflected by inclusion of mortality due to both pathways in PVA; possible attraction effects on shag and cormorant causing elevated collision risk than currently reported	No potential for significant synergistic effect	-	Possible, but risk of collision much higher than risk of entanglement, so synergistic effect not considered significant
Entanglement with Tidal Devices	No potential for significant synergistic effect	No potential for significant synergistic effect	Possible, but risk of collision much higher than risk of entanglement, so synergistic effect not considered significant	-

11.10. SUMMARY

274. This chapter provides an assessment of the potential impacts on marine ornithology receptors that may arise from marine-based activities during construction, operation / repowering and decommissioning of the Project. It describes the relevant components of the proposed Project; the consultation that has been held with stakeholders; the scope and methodology of the assessment; the avoidance and mitigation measures that have been embedded through project design; the baseline data on birds and important sites and habitats for birds acquired through desk study and survey (**Appendices 11.1 and 11.2, Volume III**) and assesses the potential impacts on marine ornithology receptors.

275. Detailed consultation with regard to the overall approach to the impact assessment on marine ornithology receptors has informed this assessment through the Ornithology TWG, which involved NRW.

276. A survey area covering the MDZ and a 2 km buffer was surveyed using a boat-based methodology over 24 months. The results of these surveys have been used to estimate the abundance and assemblage of birds using or passing across the area.

277. The impacts that could potentially arise for marine ornithology receptors during the construction, operation / repowering and decommissioning of the Project were discussed within Ornithology TWG meetings. As a result of those discussions, the potential impacts that required detailed assessment were identified as follows:

- During construction and installation:
    - Airborne noise and visual disturbance;
    - Disturbance at breeding sites; and

    - Other impacts, which consist of indirect impacts due to effects on prey and/or their habitats, as well as direct and indirect impacts through pollution events.
- During operation:
    - Airborne noise and visual disturbance;
    - Disturbance at breeding sites;
    - Collision with tidal devices;
    - Entanglement with tidal devices; and
    - Other impacts, which consist of indirect impacts due to effects on prey and/or their habitats, as well as direct and indirect impacts through pollution events.
- During decommissioning:
    - Airborne noise and visual disturbance;
    - Disturbance at breeding sites; and
    - Other impacts, which consist of indirect impacts due to effects on prey and/or their habitats, as well as direct and indirect impacts through pollution events.

278. During the construction and maintenance and decommissioning phases of the proposed Project, no impacts have been assessed to be greater than of minor adverse significance for any marine ornithology receptors.

279. During operation / repowering, underwater collision effects assessed for two scenarios have the potential to result in effects assessed to be greater than minor adverse significance, assuming a precautionary avoidance rate of 95 %. At a 40 MW worst case scenario, major adverse effects are predicted for razorbill (breeding) and the South Stack and Penlas SMP sub-colonies, and moderate adverse effects are predicted for guillemot (breeding). At an indicative 240 MW scenario, major adverse effects are predicted on guillemot (breeding), razorbill (breeding) and the South Stack and Penlas SMP sub-colonies, and moderate adverse for guillemot (non-breeding) and razorbill (non-breeding). The use of higher avoidance rates than 95 % results in a reduction in impact significance to a minor adverse level for all of the receptors listed above. However, to justify this position, a phased deployment approach, along with a detailed, multiyear monitoring program to collect further information to support the use of a higher avoidance rate would be required.

280. No other impacts predicted for any marine ornithology receptors during the operation / repowering phase of the Project have been assessed to be greater than minor adverse impact significance.

281. Two potential effects of the Project were screened in for cumulative impact assessment; airborne noise and visual disturbance (construction and operation / repowering) and collision risk. Other potential effects were screened out due to their temporary, small scale/magnitude and/or localised nature, and given the distances to other activities in the region it was concluded that there is no pathway for cumulative interaction.

282. A screening process was also carried out for potential plans and projects that might affect marine ornithology receptors cumulatively with the Project. These projects include offshore wind farms,

other marine renewable energy projects, marine aggregate extraction, oil and gas exploration and extraction, port and harbour projects, subsea cables and pipelines and commercial shipping. The risk to all marine ornithology receptors from cumulative displacement and collisions is assessed as no greater than minor adverse significance.

283. The potential for collisions and displacement from marine energy developments outside UK territorial waters (transboundary) to contribute to cumulative impacts was considered. Due to the scale of marine energy development currently proposed (both of the Project, and other projects), and the distances between them, transboundary impacts are not considered to be significant.

284. The identified impacts for the Project alone are summarised in **Table 11-34**, and no additional impact significance was found due to cumulative impacts for construction/operational airborne noise and visual disturbance, or collision.

Table 11-34 Summary of Impacts Identified for Marine Ornithology Receptors

Impact	Receptor	Value/ Sensitivity	Magnitude	Significance	Additional Mitigation Measures	Residual Impact
Construction & Installation						
Airborne Noise and Visual Disturbance	Guillemot	High/Med	Low	Minor adverse	None	Minor adverse
	All other species	Various	Negligible	Negligible		Negligible
Disturbance at Breeding Sites	Abraham's Bosom	High/Negligible for activity >300 m from colony, medium if within <300 m. WS	West Scotland

GLOSSARY OF TERMINOLOGY

Body width (m)	Body width of animal. Body width is usually around ¼ of the body length.
Dive profile	The variation of depth with elapsed time during a dive
Length (m)	Total length of animal (m) from tip to tail.

12. MARINE MAMMALS

12.1. INTRODUCTION

1. This chapter of the Environmental Statement (ES) describes the existing environment with regard to marine mammals which includes cetaceans (whales, dolphins and porpoises) and pinnipeds (seals) and assesses the potential impacts of the proposed Morlais Demonstration Zone (MDZ) and Export Cable Corridor (ECC) (hereafter referred to as 'the Project') during the construction, operation and maintenance (O&M), and decommissioning phases. Where appropriate, mitigation measures and residual impacts are presented.

2. This chapter of the ES was prepared by Royal HaskoningDHV and incorporates survey data collected by Natural Power and SEACAMS and density estimates analysed by SEACAMS.

3. This chapter also considers information from, and refers to, the following chapters within the ES:

- **Chapter 2**, Policy and Legislation;
- **Chapter 4**, Project Description;
- **Chapter 5**, Environmental Impact Assessment (EIA) Methodology;
- **Chapter 8**, Marine Water and Sediment Quality;
- **Chapter 9**, Benthic and Intertidal Ecology;
- **Chapter 10**, Fish and Shellfish Ecology; and
- **Chapter 15**, Shipping and Navigation.

4. This chapter is supported by the following Appendices:

- **Appendix 11.1**: Natural Power (2018) Morlais Demonstration Zone Bird and Marine Mammal Surveys 24-Month Technical Report;
- **Appendix 12.1**: SEACAMS (2019) Investigating methods to estimate harbour porpoise *(Phocoena phocoena*) density off West Anglesey;
- **Appendix 12.2**: Additional collision risk assessments;
- **Appendix 12.3**: Assessment of the potential for population level effects on marine mammals; and
- **Appendix 12.4**: Subacoustech (2019) Underwater noise technical note.

5. This chapter is also supported by the following documents:

- Marine Mammals - Statement of Common Ground – Menter Môn and Natural Resources Wales (**Document MOR/RHDHV/DOC/0070**);
- Information to Support Habitat Regulations Assessment (HRA) (**Document MOR/RHDHV/DOC/0067**); and
- Outline Environmental Management and Monitoring Plan (EMMP) (**Document MOR/RHDHV/DOC/0072**).

12.2. LEGISLATION, POLICY AND GUIDANCE

12.2.1. Legislation

12.2.1.1. The Habitats Directive

6. The European Union Directive on the Conservation of Natural Habitats and of Wild Fauna and Flora (92/43/EEC) (hereafter called the Habitats Directive) gives regulation to the conservation and management of natural habitats, wild fauna (except birds) and flora in Europe. Its primary aim is to maintain or restore natural habitats and wild species at a favourable conservation status.

7. Annex II of the Habitats Directive lists species for which member states are expected to establish a “consistent network of special areas of conservation”. This list includes harbour porpoise *Phocoena phocoena*, bottlenose dolphin *Tursiops truncatus* along with the grey seal *Halichoerus grypus* and harbour seal *Phoca vitulina* all of which are relevant to the Project.

8. Although not legally binding, the European Commission’s Guidance document on the strict protection of animal species of Community interest under the Habitats Directive (European Commission (EC) 2007) states that:

   “*In order to assess a disturbance, consideration must be given to its effect on the conservation status of the species at population level and biogeographic level in a Member State. For instance, any disturbing activity that affects the survival chances, the breeding success or the reproductive ability of a protected species or leads to a reduction in the occupied area should be regarded as a “disturbance” in terms of Article 12”.*

9. The Habitats Directive protects all species of cetaceans under Annex IV as European Protected Species (EPS), being classed as endangered, vulnerable or rare, and grey and harbour seals are protected under Annex V which requires their exploitation or removal from the wild to be subject to management measures. Harbour porpoise, bottlenose dolphin and both seal species are additionally listed under Annex II, which requires member states to designate sites, identified as being key areas for their life and reproduction, as Special Areas of Conservation (SACs).

10. Article 12 of the Habitats Directive requires member states to establish stricter protection for species within their natural range; prohibiting all forms of deliberate capture or killing, deliberate disturbance (particularly during breeding and rearing periods, hibernations and migration) and the deterioration or destruction of breeding and resting sites.

12.2.1.2. The Habitats Regulations

11. The Conservation of Habitats and Species Regulations 2017 and the Conservation of Offshore Marine Habitats and Species Regulations 2017 (collectively referred to as ‘the Habitats Regulations 2017’) transpose the Habitats Directive into national law. The Habitats Regulations place an obligation on ‘competent authorities’ to carry out an Appropriate Assessment (AA) of any proposal likely to have a significant effect on a Natura 2000 site, to seek advice from Statutory Nature Conservation Bodies (SNCBs) and to reject an application that would have an adverse effect on the integrity of a Natura 2000 site except under very tightly constrained conditions.

12. All cetacean species are listed under Schedule 2 and defined as EPS and all seals are listed under Schedule 4 (animals which may not be captured or killed in certain ways).

- Under the Habitats Regulations 2017 a person is guilty of an offence if that person:
- Deliberately captures, injures or kills a wild animal belonging to a species with EPS status;
- Deliberately disturbs such animal; or
- Damages or destroys any resting or breeding place of such animal.

13. However, there is a provision to apply for an EPS licence where any of the above is expected to occur, provided there is no satisfactory alternative, and there will be no long-term detrimental effects. This is especially relevant to marine mammals and the likelihood of disturbance due to marine activities.

14. As in the Habitats Directive, there is a requirement to create SACs for species listed under Annex II (i.e. harbour porpoise, bottlenose dolphin, grey and harbour seals) and to advise on what marine operations may adversely affect the integrity of the site.

15. There are a number of provisions within the regulations that protect marine species from harmful activities. EPS, as listed under Annex IV of the Habitats Directive, are protected from:

- The deliberate capture, injury, killing;
- Any disturbance that is likely to result in a significant impact to the ability of any species group to survive, breed, rear or nurture their young, to disrupt a species' hibernation or migrations, or to affect significantly the local distributions or abundance of the species; and
- Damage or destroy any breeding or resting site.

12.2.1.3. Summary of relevant legislation

16. **Table 12-1** provides an overview of national and international legislation in relation to marine mammals.

Table 12-1 National and international legislation in relation to marine mammals

Legislation	Level of Protection	Species	Overview
Agreement on the Conservation of Small Cetaceans of the Baltic and North Seas (ASCOBANS)	International	Odontocetes	Formulated in 1992, this agreement has been signed by 10 European countries bordering the Baltic and North Seas (including the English Channel) and includes the United Kingdom (UK). Under the Agreement, provision is made for the protection of specific areas, monitoring, research, information exchange, pollution control and increasing public awareness of small cetaceans.
The Berne Convention 1979	International	All cetaceans, grey seal and harbour seal	The Convention conveys special protection to those species that are

Legislation	Level of Protection	Species	Overview
			vulnerable or endangered. Appendix II (strictly protected fauna): 19 species of cetacean. Appendix III (protected fauna): all remaining cetaceans, grey and harbour seal. Although an international convention, it is implemented within the UK through the Wildlife and Countryside Act 1981.
The Bonn Convention 1979	International	All cetaceans	Protects migratory wild animals across all, or part of their natural range, through international co-operation, and relates particularly to those species in danger of extinction. One of the measures identified is the adoption of legally binding agreements, including ASCOBANS.
Oslo and Paris Convention for the Protection of the Marine Environment 1992 (OSPAR)	International	Bowhead whale *Balaena mysticetus*, northern right whale *Eubalaena glacialis*, blue whale *Balaenoptera musculus*, and harbour porpoise	OSPAR has established a list of threatened and/or declining species in the North East Atlantic. These species have been targeted as part of further work on the conservation and protection of marine biodiversity under Annex V of the OSPAR Convention. The list seeks to complement, but not duplicate, the work under the European Commission (EC) Habitats and Birds directives and measures under the Berne Convention and the Bonn Convention.
International Convention for the Regulation of Whaling 1956	International	All cetacean species	This Convention established the International Whaling Commission (IWC) who regulates the direct exploitation and conservation of large whales (in particular sperm whale and large baleen whales) as a resource and the impact of human activities on cetaceans. The regulation considered scientific matters related to small cetaceans, in particular the enforcing a moratorium on commercial whaling which came into force in 1986.
Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) 1975	International	All cetacean species	Prohibits the international trade in species listed in Appendix 1 (including sperm whales, northern right whales, and baleen whales) and allows for the controlled trade of all other cetacean species.
Convention on Biological Diversity (CBD) 1993	International	All marine mammal species	Requires signatories to identify processes and activities that are likely to have impacts on the conservation of and sustainable use of biological diversity, inducing the introduction of appropriate procedures requiring an EIA and mitigation procedures.

Legislation	Level of Protection	Species	Overview
The Conservation of Habitats and Species Regulations 2017 and The Conservation of Offshore Marine Habitats and Species Regulations 2017	National	All cetaceans, grey and harbour seal	'The Habitats Regulations 2017'. Provisions of The Habitats Regulations are described further above. It should be noted that the Habitats Regulations apply onshore, within the territorial seas and to marine areas within UK jurisdiction, beyond 12 nautical miles (nm).
The Wildlife and Countryside Act 1981 (as amended)	National	All cetaceans	All cetaceans listed on Schedule 5 are fully protected within UK territorial waters. The Act protects them from killing or injury, sale, destruction of a particular habitat (which they use for protection or shelter) and disturbance. Short-beaked common dolphin *Delphinus delphis*, bottlenose dolphin and harbour porpoise are listed on Schedule 6 of the Act. Under the Act these species are prohibited from being used as a decoy to attract other animals. The Act also prohibits the use of vehicles in immediate pursuit to take, kill or drive them, it prevents nets, traps or electrical devices from being set in such a way that would injure them and prevents the use of nets or sounds to trap or snare them.
The Countryside and Rights of Way Act (CRoW) 2000	National	All cetaceans	Under the CRoW Act 2000, it is an offence to intentionally or recklessly disturb any wild animal included under Schedule 5 of the Wildlife and Countryside Act.
Conservation of Seals Act 1970	England and Wales	Grey and harbour seal	Provides closed seasons, during which it is an offence to take or kill any seal, except under licence or in certain circumstances (grey seal: 1 September to 31 December; harbour seal: 1 June to 31 August).

12.2.2. Policy and Plans

17. An overview of the relevant policy and plans for the Project is provided in **Chapter 2, Policy and Legislation**, this includes:

- National Policy Statements;
- Marine Policy Statement;
- Welsh National Marine Plan;
- Planning Policy Wales; and
- Anglesey and Gwynedd Joint Local Development Plan.

18. **Table 11-2** in **Chapter 11 Marine Ornithology** outlines the National (UK and Wales) planning policy, plans and measures that are also relevant to marine mammals.

19. The assessment of potential impacts upon marine mammals has been made with specific reference to the relevant National Policy Statements (NPS)[1]. These are the principal decision-making documents for Nationally Significant Infrastructure Projects (NSIP).

20. The Overarching NPS for Energy (EN-1) sets out the UK Government's policy for delivery of major energy infrastructure, with generic considerations which are further considered in the technology-specific NPSs such as the NPS for Renewable Energy Infrastructure (EN-3). Although, NPS EN-3 states "*this NPS does not cover other types of renewable energy generation that are not at present technically viable over 50 MW onshore or over 100 MW offshore such as schemes that generate electricity from tidal stream or wave power*.", therefore relevant requirements have been referred to until a revision to this NPS or a separate NPS is provided for tidal range schemes greater than 100 MW.

21. The specific assessment requirements for marine mammals, as detailed in NPS EN-1 and EN-3, are summarised in **Table 12-2**, together with an indication of the paragraph numbers of the chapter where each is addressed.

Table 12-2 NPS EN-1 and EN-3 Assessment Requirements

NPS Requirement	NPS Reference	ES Reference
'Where the development is subject to EIA [Environmental Impact Assessment] the applicant should ensure that the ES [Environmental Statement] clearly sets out any effects on internationally, nationally and locally designated sites of ecological or geological conservation importance, on protected species and on habitats and other species identified as being of principal importance for the conservation of biodiversity. The applicant should provide environmental information proportionate to the infrastructure where EIA is not required to help the Infrastructure Planning Commission (IPC) [now the Planning Inspectorate and the Secretary of State (SoS)] consider thoroughly the potential effects of a proposed project.'	**NPS EN-1 Section 5.3 Paragraph 5.3.3**	**Section 12.6**
'The applicant should show how the project has taken advantage of opportunities to conserve and enhance biodiversity and geological conservation interests.'	**NPS EN-1 Section 5.3 Paragraph 5.3.4**	**Section 12.6.2 and EMMP** (**Document MOR/RHDHV/DOC/0072**)
'When considering the application, the IPC will have regard to the Government's biodiversity strategy as (sic) set out in 'Working with the grain of nature', which aims to halt or reverse declines in priority habitats and species; accept the importance of biodiversity to quality of life. The IPC will consider this in relation to the context of climate change. As a general principle, and subject to the specific policies below, development should aim to avoid significant harm to	**NPS EN-1 Section 5.3 Paragraph 5.3.5-5.3.8**	**Section 12.6.2 and EMMP** (**Document MOR/RHDHV/DOC/0072**)

[1] https://www.gov.uk/government/publications/national-policy-statements-for-energy-infrastructure

NPS Requirement	NPS Reference	ES Reference
biodiversity and geological conservation interests, including through mitigation and consideration of reasonable alternatives (as set out in section 4.4 above); where significant harm cannot be avoided, then appropriate compensation measures should be sought. In taking decisions, the IPC should ensure that appropriate weight is attached to designated sites of international, national and local importance; protected species; habitats and other species of principal importance for the conservation of biodiversity; and to biodiversity and geological interests within the wider environment.'		
'The most important sites for biodiversity are those identified through international conventions and European Directives. The Habitats Regulations provide statutory protection for these sites but do not provide statutory protection for potential Special Protection Areas (pSPAs) before they have been classified as a Special Protection Area. For the purposes of considering development proposals affecting them, as a matter of policy the Government wishes pSPAs to be considered in the same way as if they had already been classified.'	**NPS EN-1 Section 5.3 Paragraph 5.3.9**	**Information to Support HRA (Document MOR/RHDHV/DOC/0067)**
The applicant should include appropriate mitigation measures as an integral part of the proposed development and demonstrate that: • during construction, they will seek to ensure that activities will be confined to the minimum areas required for the works; • during construction and operation best practice will be followed to ensure that risk of disturbance or damage to species or habitats is minimised, including as a consequence of transport access arrangements; • habitats will, where practicable, be restored after construction works have finished; and • opportunities will be taken to enhance existing habitats and, where practicable, to create new habitats of value within the site landscaping proposals.'	**NPS EN-1 Section 5.3 Paragraph 5.3.18**	**Section 12.6.2 and EMMP** (**Document MOR/RHDHV/DOC/0072**)
Where necessary, assessment of the effects on marine mammals should include details of: • likely feeding areas; • known birthing areas/haul out sites; • nursery grounds; • known migration or commuting routes; • duration of the potentially disturbing activity including cumulative/in-combination effects with other plans or projects; • baseline noise levels; • predicted noise levels in relation to mortality, permanent threshold shift (PTS) and temporary threshold shift (TTS); and • operational noise.	**NPS EN-3 Paragraph 2.6.92**	**Section 12.5 and Section 12.6**

NPS Requirement	NPS Reference	ES Reference
The IPC [now SoS] should be satisfied that the preferred methods of construction, in particular the construction method needed for the proposed foundations and the preferred foundation type, where known at the time of application, are designed so as to reasonably minimise significant disturbance effects on marine mammals. Unless suitable noise mitigation measures can be imposed by requirements to any development consent the IPC [now SoS] may refuse the application.	**NPS EN-3 Paragraph 2.6.94**	**Chapter 4; Section 12.6, including Section 12.6.2**
The conservation status of marine European Protected Species and seals are of relevance to the IPC [now SoS].	**NPS EN-3 Paragraph 2.6.95**	**Section 12.5 and Information to Support HRA (Document MOR/RHDHV/DOC/0067)**
Monitoring of the surrounding area before and during the piling procedure can be undertaken.	**NPS EN-3 Paragraph 2.6.97**	**Section 12.4.2 and EMMP** (**Document MOR/RHDHV/DOC/0072**)
During construction, 24-hour working practices may be employed so that the overall construction programme and the potential for impacts to marine mammal communities is reduced in time.	**NPS EN-3 Paragraph 2.6.98**	**Section 12.6, including Section 12.6.1**

22. **Table 12-3** sets out other national and regional policies which are particularly relevant to the Project.

Table 12-3 National and Regional Policy Requirements Relevant to Marine Mammals

Policy Description	Reference	ES Reference
MPS		
Noise resulting from a proposed activity or development in the marine area or in coastal and estuarine waters can have adverse effects on biodiversity although knowledge of the extent of impacts is limited and there are few systematic monitoring programmes to verify adverse effects. Man-made sound emitted within the marine environment can potentially affect marine organisms in various ways. It has the potential to mask biologically relevant signals; it can lead to a variety of behavioural reactions, affect hearing organs and injure or even kill marine life. Manmade sound sources of primary concern with regard to disturbance of marine life are explosions, shipping, seismic surveys, offshore construction and offshore industrial activities, for example dredging, drilling and piling, sonar of various types and acoustic deterrent devices.	Section 2.6.3.1	Underwater noise modelling has been undertaken to inform the impact assessment for construction and operation of the Project. Impact assessment is presented in **Sections 12.6.3.1** to **12.6.3.4**, and **12.6.4.1** to **12.6.4.3**.
Renewable energy developments can potentially have adverse impacts on marine fish and mammals, primarily through construction noise and may displace fishing activity and have direct or indirect impacts on other users of the sea, including mariners. Certain bird species may be displaced by offshore wind turbines, which also have the potential to form barriers to migration or present a collision risk for birds. Their foundation designs are likely to have an effect on hydrodynamics and consequent sediment movement. This includes potential scouring of	Section 3.3.24	See above

Policy Description	Reference	ES Reference
sediments around the bases of turbines. These and other potential adverse impacts, together with potential mitigation measures, are considered in the National Policy Statement for Renewable Energy Infrastructure (EN-3).		
Marine energy deployments, that is wave and tidal deployments, may pose potential risks to the environment if inappropriately sited. However, the level of risk and ecological significance is largely unknown since, in particular, tidal stream and wave technologies are at a relatively early stage of development. Studies of tidal range technologies, including barrages, have indicated that these structures can have adverse impacts on migratory fish and bird species and on the hydrodynamics of the estuarine environments in which they are situated. To underpin the marine planning process further research is needed to develop a better understanding of the potential impacts that marine technologies might have on potentially sensitive environmental features. For example, adaptation and mitigation methods for such impacts may be supported by detailed monitoring programmes and co-ordinated research initiatives, including post deployment of devices.	Section 3.3.25	Collision risk with tidal devices during operation of the Project is discussed in **Section 12.6.4.5.**
Draft WNMP		
Proposals should demonstrate how they: · avoid adverse impacts on individual Marine Protected Areas (MPAs) and the coherence of the network as a whole; · have regard to the measures to manage MPAs; and · avoid adverse impacts on non-marine designated sites.	ENV_02: Marine Protected Areas	The conservation importance of marine mammal species in the vicinity of the MDZ is presented in **Section 12.5**. Information to support an HRA is presented in Document MOR/RHDHV/DOC/0067.
Proposals should demonstrate that they have considered man-made noise impacts on the marine environment and, in order of preference: a) avoid adverse impacts; and/or b) minimise impacts where they cannot be avoided; and/or c) mitigate impacts where they cannot be minimised. If significant adverse impacts cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding	ENV_05: Underwater noise	Underwater noise modelling has been undertaken to inform the impact assessment for construction and operation of the Project. Impact assessment is presented in **Sections 12.6.3.1** to **12.6.3.4**, and **12.6.4.1** to **12.6.4.3**.
Proposals should demonstrate that they have assessed potential cumulative effects and, in order of preference: a) avoid adverse effects; and/or b) minimise effects where they cannot be avoided; and/or c) mitigate effects where they cannot be minimised. If significant adverse effects cannot be adequately addressed, proposals should present a clear and convincing justification for proceeding. Proposals that contribute to positive cumulative effects are encouraged.	GOV_01: Cumulative effects	Cumulative impacts are assessed in **Section 12.6.6** and in **Chapter 26**
Anglesey and Gwynedd Joint Local Development Plan (JLDP)		
All impacts on landscape character, heritage assets and natural resources have been adequately mitigated,	Policy ADN 3: Other Renewable Energy	The impact assessment is included within **Section**

Policy Description	Reference	ES Reference
ensuring that the special qualities of all locally, nationally and internationally important landscape, biodiversity and heritage designations, including, where appropriate, their settings are conserved or enhanced	and Low Carbon Technologies	**12.6** and includes mitigation measures to reduce impact significance.

12.2.3. Guidance

23. The principal guidance documents used to inform the assessment of potential impacts on marine mammals, include, but are not limited to:

- The Protection of Marine EPS from Injury and Disturbance: Draft Guidance for the Marine Area in England and Wales and the UK Offshore Marine Area (Joint Nature Conservation Committee (JNCC) *et al*., 2010).
- Guidelines for Ecological Impact Assessment in the UK and Ireland: Terrestrial, Freshwater and Coastal (Chartered Institute of Ecology and Environmental Management (CIEEM), 2016).
- Environmental Impact Assessment for offshore renewable energy projects – guide (British Standards Institution (BSI), 2015).
- Approaches to Marine Mammal Monitoring at Marine Renewable Energy Developments Final Report (Sea Mammal Research Unit Ltd (SMRU Ltd) on behalf of The Crown Estate, 2010).
- Guidelines for Data Acquisition to Support Marine Environmental Assessments of Offshore Renewable Energy Projects (Centre for the Environment and Fisheries and Aquaculture Science (Cefas), 2012).
- Assessing collision risk between underwater turbines and marine wildlife. Scottish Natural Heritage (SNH) (2016) guidance note.
- Guidance to inform marine mammal site characterisation requirements at wave and tidal stream energy sites in Wales (Sparling *et al*., 2015).
- Defining Project Envelopes for Marine Energy Projects: Review and Tidal Energy Test Facility and Marine Mammals Case Study (Sparling and Smith, 2019, unpublished).

12.2.3.1. EPS Guidance

24. JNCC *et al*. (2010) provides draft guidance concerning the Regulations on the deliberate disturbance of marine EPS, provides an interpretation of the regulations in greater detail, including for pile driving operations (JNCC, 2010a), seismic surveys (JNCC, 2017a) and the use of explosives (JNCC, 2010b).

25. The draft guidance provides advice on activities at sea that could potentially cause deliberate injury or disturbance to marine mammals and summarises information and sensitivities of the species to which these regulations apply. The guidance refers to the European Commission's Guidance document (EC, 2007) stating that, there must be some ecological impact in order for significant disturbance to occur.

26. The draft guidance provides the following interpretations of deliberate injury and disturbance offences under both the Habitats Regulations and Offshore Regulations (now the Habitats Regulations 2017), as detailed in the paragraphs below:

"Deliberate actions are to be understood as actions by a person who knows, in light of the relevant legislation that applies to the species involved, and the general information delivered to the public, that his action will most likely lead to an offence against a species, but intends this offence or, if not, consciously accepts the foreseeable results of his action;

Certain activities that produce loud sounds in areas where EPS could be present have the potential to result in an injury offence, unless appropriate mitigation measures are implemented to prevent the exposure of animals to sound levels capable of causing injury."

27. For the purposes of marine users, the draft guidance states that a disturbance which can cause offence should be interpreted as:

"Disturbance which is significant in that it is likely to be detrimental to the animals of an EPS or significantly affect their local abundance or distribution."

28. The draft guidelines further states that a disturbance offence is more likely where an activity causes persistent noise in an area for long periods of time, and a disturbance offence is more likely to occur when there is a risk of:

- Animals incurring sustained or chronic disruption of behaviour scoring five or more in the Southall *et al*. (2007) behavioural response severity scale; or
- Animals being displaced from the area, with redistribution significantly different from natural variation.

29. The JNCC *et al*. (2010) draft guidance highlights that sporadic "trivial disturbance" should not be considered as a disturbance offence under Article 12.

30. In order to assess whether a disturbance could be considered non-trivial in relation to the objectives of the Directive, JNCC *et al*. (2010) suggest that consideration should be given to the definition of the Favourable Conservation Status (FCS; see **Section 12.2.3.2**) of a species given in Article 1(i) of the Habitats Directive. There are three parameters that determine when the conservation status of a species can be taken as favourable:

- Population dynamics data on the species concerned indicate that it is maintaining itself on a long-term basis as a viable element of its natural habitats.
- The natural range of the species is neither being reduced nor is likely to be reduced for the foreseeable future.
- There is, and will probably continue to be, a sufficiently large habitat to maintain its populations on a long-term basis.

31. Therefore, any action that could increase the risk of a long-term decline of the population, increase the risk of a reduction of the range of the species, and/or increase the risk of a reduction of the size of the habitat of the species can be regarded as a disturbance under the Regulations.

For a disturbance to be considered non-trivial, the disturbance to marine EPS would need to be likely to at least increase the risk of a certain negative impact on the species at FCS.

32. JNCC *et al*. (2010) do not provide guidance as to what would constitute a 'significant group' or proportion of the population, but provide some discussion on how to assess whether the numbers potentially affected could be of concern for a population's FCS.

33. JNCC *et al*. (2010) state that:

"In any population with a positive rate of growth, or a population remaining stable at what is assumed to be the environmental carrying capacity, a certain number of animals can potentially be removed as a consequence of anthropogenic activities (e.g. through killing, injury or permanent loss of reproductive ability), in addition to natural mortality, without causing the population to decrease in numbers, or preventing recovery, if the population is depleted. Beyond a certain threshold however, there could be a detrimental effect on the population".

34. Further discussion on the use of thresholds for significance and the permanent or temporary nature of any disturbance is considered by defining the magnitude of potential effect in this assessment (**Section 12.4.4**). Consideration of any potential essential habitat or geographical structuring of EPS is provided in the Existing Environment section (**Section 12.5**) of this chapter.

35. In order to assess the number of individuals from a species that could be removed from the regional population through injury or disturbance without compromising the FCS, the EIA considers:

- The numbers affected in relation to the best and most recent estimate of population size; and
- The threshold for potential impact on the FCS, which will depend on:
  - The species' / populations' life-history;
  - The species' FCS assessment in UK waters; and
  - Other pressures encountered by the population (cumulative effects).

36. One of the key parameters for consideration within this assessment is the population size. The EPS Guidance advises that the best available abundance estimates could be used as a baseline population size, taking account of any evidence of regional population structuring (JNCC *et al*., 2010).

37. An EPS licence is required if the risk of injury or disturbance to cetacean species is assessed as likely under the Habitats Regulations 2017.

38. If a licence is required, an application must be submitted, the assessment of which comprises three tests, namely:

- Whether the activity falls within one of the purposes specified in Regulation 55 of the Habitats Regulations. Only the purpose of "preserving public health or public safety or other imperative reasons of overriding public interest, including those of a social or economic nature and beneficial consequences of primary importance for the environment" is of relevance to marine mammals in this context;

- That there are no satisfactory alternatives to the activity proposed (that would not incur the risk of offence); and
- That the licensing of the activity will not result in a negative impact on the species'/ population's FCS.

39. Under the definitions of 'deliberate disturbance' in the Habitats Regulations, chronic exposure and / or displacement of animals could be regarded as a disturbance offence.

40. If required, the EPS licence application will be submitted post-consent. At this time, the project design envelope will have been further refined, as well as full details of the mitigation and monitoring measures that will be in place.

12.2.3.2. Favourable Conservation Status (FCS)

41. Member states report back to the European Union (EU) every six years on the Conservation Status of marine EPS. Based on the most recent 2007-2012 reporting by the Joint Nature and Conservation Committee (JNCC, 2013), seven species of the 11 cetacean species were assessed as having a 'favourable' Conservation Status (**Table 12-4**).

42. Four of 11 cetacean species were assessed as having an 'unknown' Conservation Status (JNCC, 2013). This is a result of a lack of recent population estimates that encompassed their natural range in UK and adjacent waters and / or having no evidence to determine long-term trends in population abundance.

43. Another 17 species were considered to be uncommon, rare or very rare in occurrence, so it was not possible to ascertain their Conservation Status (JNCC, 2013).

Table 12-4 FCS assessment of cetacean species in Annex IV of the Habitats Directive occurring in UK and adjacent waters (JNCC, 2013)

Species	FCS assessment
Atlantic white-sided dolphin *Lagenorhynchus acutus*	Favourable
Bottlenose dolphin *Tursiops truncatus*	Favourable
Common dolphin *Delphinus delphis*	Favourable
Fin whale *Balaenoptera physalus*	Favourable
Harbour porpoise *Phocoena phocoena*	Favourable
Killer whale *Orcinus orca*	Unknown
Long-finned pilot whale *Globicephala melas*	Unknown
Minke whale *Balaenoptera acutorostrata*	Favourable
Risso's dolphin *Grampus griseus*	Unknown
Sperm whale *Physeter macrocephalus*	Unknown
White-beaked dolphin *Lagenorhynchus albirostris*	Favourable

12.3. CONSULTATION

44. Details on the consultation for the Project are provided in **Chapter 6, Consultation**. Scoping and consultation have been on-going throughout the EIA and have supported the scope of the baseline characterisation work and ensuring that the requirements of the regulators and their

advisors are met. **Table 12-5** summarises relevant marine mammal consultation responses received prior to and during preparation of the ES and which were considered in this Chapter. A full list of consultation responses and how they have been taken into account in finalising the Project is presented in **Chapter 6, Consultation**.

45. A “statement of common ground” (SoCG) and technical working group (TWG) approach has been used for the management of key issues, with technical experts from Natural Resources Wales (NRW) and Royal HaskoningDHV on behalf of Menter Môn. **Table 12-5** includes the key points from the SoCG and marine mammal TWG meetings.

Table 12-5 Summary of marine mammal consultation responses

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping comments	Study area: The Scoping Report has utilised an initial search area of up to 50 km. The Applicant is recommended to agree the study area with NRW, noting NRW’s comments (see Appendix 1 of this Scoping Opinion) of the need to utilise the relevant marine mammal management units.	The relevant marine mammal management units have been used for each species as outlined in **Section 12.4.1**.
Planning Inspectorate	2018 Scoping comments	Underwater noise: The ES should set out the noise levels at which effects on marine mammals and basking sharks occur and explain how these levels have been derived.	The underwater noise assessment, including the thresholds and criteria are presented in **Section 12.6.3.1.1**.
Planning Inspectorate	2018 Scoping comments	Disturbance: Disturbance from the presence of construction and operational vessels should be assessed, where significant effects are likely.	The potential disturbance from the presence of vessels during construction has been assessed in **Section12.6.3.3** and for operational vessels in **Section 12.6.4.3**.
Planning Inspectorate	2018 Scoping comments	Displacement: The potential for displacement from underwater noise has been acknowledged in the Scoping Report; however, the resultant indirect effects have not been considered e.g. energy expenditure in avoiding the area. This should be assessed within the ES.	The potential for displacement from underwater noise has been assessed in **Section 12.6.3** and **12.6.4**.
Planning Inspectorate	2018 Scoping comments	EIA Baseline Characterisation: The Scoping Report has not proposed any site specific surveys to inform the baseline and it is unclear whether the marine mammal surveys which have been undertaken alongside the offshore ornithological surveys cover the application site. The Applicant should consider the applicability of existing data to the Proposed Works and application site. It is recommended that the sufficiency of any existing data, and the need for any site specific surveys, is discussed with NRW.	The baseline characterisation takes into account the site specific marine mammal surveys undertaken by Natural Power and SEACAMS, as outlined in **Section 12.4.2**.

Consultee	Date/Document	Comment	Response
Planning Inspectorate	2018 Scoping comments	Collision Risk: The Scoping Report states that collision risk would be determined through a literature review of similar studies and the results taken from SeaGen and the MeyGen projects. Therefore, it is assumed that site specific collision risk modelling will not be undertaken. However, the Scoping Report fails to provide the information necessary to obviate the need for collision risk modelling taking into account the chosen device(s) and the location of the Proposed Works. The ES should ensure that impacts which may result in likely significant effects to these species are assessed, including those from collision risk. The Applicant should make effort to discuss and agree the approach to the assessment with NRW. If reliance is placed on existing information to demonstrate an absence of likely significant effect, the ES should explain why the studies referenced are applicable to the Proposed Works.	In **Section 12.6.4.4.1**, site specific collision risk modelling has been undertaken for a range of different devices based on the SNH (2016) ERM and CRM models.
Planning Inspectorate	2018 Scoping comments	Underwater baseline noise: The Applicant's attention is drawn to the existence of the Defra Marine Noise Registry which could inform the baseline noise environment.	The marine noise registry data was checked, however no ambient underwater noise levels were available for the MDZ area. Therefore, information from other studies has been included, as outlined in **Section 12.6.3.1.1**.
Planning Inspectorate	2018 Scoping comments	EMF: The Scoping Report has identified the potential for EMF to affect benthic ecology and migratory fish; however, no reference has been made to potential impacts from EMF on marine mammals. Any likely significant effects to marine mammals from EMF should be assessed within the ES.	The potential effects of EMF have been assessed in **Section 12.6.4.9**.
Planning Inspectorate	2018 Scoping comments	Changes to prey resource: Potential impacts from a decrease in water quality has been identified as a potential impact for fish and shellfish. The resultant indirect impacts for marine mammals, basking sharks and reptiles should be assessed.	The potential changes to prey resources during construction have been assessed in **Section 12.6.3.8** and during operation in **Section 12.6.4.12**.
NRW	2018 Scoping comments	In section 8.1.1.2 it states that "due to the wide ranging nature of offshore ecological receptors such as … marine mammal receptors, an initial search of up to 50 km has been used for these receptors". We advise that with regard to marine mammals, rather than the 50 km search area proposed, the relevant marine mammal management units provide the appropriate spatial extent for screening in marine mammal protected sites (including	The relevant marine mammal management units have been used for each species as outlined in **Section 12.4.1**.

Consultee	Date/Document	Comment	Response
		SSSIs where appropriate) (see IAMMWG, 2015).	
NRW	2018 Scoping comments	For Annex II marine mammal species, the Welsh SACs within the relevant management units are as follows: Harbour porpoise Management Unit: Celtic & Irish Sea Welsh SACs with harbour porpoise as a feature within the Management Unit: North Anglesey Marine West Wales Marine Bristol Channel Approaches Bottlenose dolphin Management Unit: Irish Sea Welsh SACs with bottlenose dolphin as a feature within the Management Unit: Pen Llyn a'r Sarnau Cardigan Bay Grey Seal Management Unit: South and West England and Wales Welsh SACs with grey seal as a feature within the Management Unit: Pen Llyn a'r Sarnau Cardigan Bay Pembrokeshire Marine	As outlined in **Section 12.5.8**, these sites have been assessed in the information for the HRA (**Document MOR/RHDHV/DOC/0067**).
NRW	2018 Scoping comments	Please note that that the series of Harbour Porpoise SACs in the UK are now officially adopted by Europe and must be formally considered in HRA. Sites outside of Welsh waters (e.g. in Irish, English, Northern Irish, Scottish waters) should also be screened in based on their presence in the relevant management unit.	All designated sites within the relevant MUs, including harbour porpoise SACs, have been considered in the HRA screening (**Document MOR/RHDHV/DOC/0067**).
NRW	2018 Scoping comments	The nearshore and inshore waters of the Anglesey coast are important for cetaceans and seals. We advise that the scope of the ES assessment must consider the impacts of all stages of the development (construction, operation and decommissioning) on the following marine mammal species: harbour porpoise, common dolphin, Risso's dolphin, grey seal, minke whale and bottlenose dolphin.	As outlined in **Section 12.5** and agreed with NRW at the second marine mammal TWG meeting in February 2019, the ES assessment considers the impacts of all stages of the development (construction, operation and decommissioning) on the following marine mammal species: harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale and grey seal.
NRW	2018 Scoping comments	Some species might present a high risk and require a more quantitative approach to assessment than others, for example bottlenose dolphin, grey seal, harbour	Where possible, all assessments in the ES have been based on a quantitative approach.

Consultee	Date/Document	Comment	Response
		porpoise, which are all SAC species from nearby sites.	This has been put into the context of the SAC sites in the information for the HRA (**Document MOR/RHDHV/DOC/0067**).
NRW	2018 Scoping comments	Please note that bottlenose dolphin in the demonstration zone area are likely to be from Cardigan Bay SAC and Pen Llyn ar Sarnau SACs in the Irish Sea Management Unit (not just Cardigan Bay SAC).	This has been taken into account in the assessments for the ES (see **Section 12.5.2**) and in the information for the HRA (**Document MOR/RHDHV/DOC/0067**).
NRW	2018 Scoping comments	There are regionally important grey seal pupping sites on Anglesey, including on Holy Island (see Westcott and Stringell 2003). An NRW commissioned census of grey seal pupping abundance and distribution has recently been completed and indicates at least a doubling of pup production in North Wales (Banga *et al*. 2018 in prep – this paper might be available in time for consideration within the ES).	Grey seal pupping sites on Anglesey have been taken into account (as outlined in **Section 12.5.6**), based on Clarke *et al*. (2018). Grey Seal Pup Production and Distribution in North Wales.
NRW	2018 Scoping comments	The use of the demonstration zone and surrounding area by marine mammals will need to be assessed both spatially and temporally. The spatial extent of activities and operations and marine mammal protected sites should be guided by the relevant marine mammal management units (IAMMWG, 2015).	**Section 12.5**, outlines the distribution and occurrence for each species, including the relevant MUs. Where relevant, the potential impacts in **Section12.6** have been assessed both spatially and temporally.
NRW	2018 Scoping comments	Table 8.5 currently presents very broad appraisal of the potential impacts to be assessed; we consider that a more detailed list of possible impact pathways needs to be considered and presented in the ES. Where a particular impact is ruled out as being not significant, it is important that the decision is based on clear evidence. The impact pathways identified in the ES should also be considered in the cumulative impact assessment and HRA, where appropriate. We recommend that the ORJIP Ocean Energy Forward Look provides a useful start for prioritising impact pathways and evidence needs (see http://www.orjip.org.uk/documents).	**Section 12.6.1** provides details on the potential impacts and possible pathways assessed in the ES and **Section 12.4.4** outlines the EIA methodology. The impact pathways have also considered, where appropriate, in the cumulative impact assessment (**Section 12.6.6**) and in the information for the HRA (**Document MOR/RHDHV/DOC/0067**). Determining the potential impacts and pathways took into account numerous information sources, including ORJIP (2017) Ocean Energy Forward Look.

Consultee	Date/Document	Comment	Response
NRW	2018 Scoping comments	At this stage, the key issues would appear to relate to displacement, disturbance and collision during operation and noise impacts during construction, operation and decommissioning. There, however, be will be other impacts to consider, including indirect effects on prey species and cumulative effects.	**Section 12.6.1** provides an overview of the potential impacts that have been assessed for marine mammals, including potential changes in prey availability (**Section 12.6.3.8** and **12.6.4.12**) and cumulative impacts (**Section 12.6.6**).
NRW	2018 Scoping comments	We advise that it is likely that the key issue of collision risk during operation will need to be considered in quantitative detail. The potential for population level effects on marine mammals will need to be considered where significant impact pathways have been identified. For the assessment of marine mammal collision risk, we advise that the use of modelling frameworks such as the Population Consequences of Disturbance (PCoD) or toll quotas such as Potential Biological Removal should be considered.	In **Section 12.6.4.4.1**, site specific collision risk modelling has been undertaken for a range of different devices based on the SNH (2016) ERM and CRM models. The potential for population level effects on marine mammals have been assessed, where significant impact pathways have been identified, in **Appendix 12.3**.
NRW	2018 Scoping comments	We advise that the Sparling et al 2015 publication “Guidance to inform marine mammal site characterisation requirements at wave and tidal stream energy sites in Wales” should be followed to assist in determining the level of baseline characterisation required to inform the ES.	Sparling *et al*. (2015) and other guidance and information sources have been taken into consideration in **Sections 12.5** and **12.6**.
NRW	2018 Scoping comments	Note that although a literature review and results of collision risk analysis from similar studies (e.g. SeaGen and the MeyGen projects) will be informative, we advise that there will likely be a need to adapt present models to fit the chosen device(s) and unique location characteristics (open tidal site).	In **Section 12.6.4.4.1**, site specific collision risk modelling has been undertaken for a range of different devices based on the SNH (2016) ERM and CRM models.
NRW	2018 Scoping comments	The proposed baseline underwater noise monitoring survey should be undertaken in line with the latest relevant guidelines.	Noise data were collected by SEACAMS for the MDZ and have been used in the characterisation of the site.
NRW	2018 Scoping comments	No information is provided in the scoping report on the proposed approach to assessing potential underwater noise effects. This should follow the latest guiding principles for the assessment of the impacts of underwater noise. This includes applying an appropriate acoustic model, published exposure criteria or acoustic thresholds and relevant noise sources and model input data. The limitations and constraints of any approach should be set out.	The underwater noise assessment, including the thresholds and criteria are presented in **Section 12.6.3.1.1**. The underwater noise assessments also include, where possible, a general review of the latest available scientific

Consultee	Date/Document	Comment	Response
		The noise assessment should also include a general review of the latest available scientific evidence of the observed responses of marine mammals to different types of underwater sound for context.	evidence of the observed responses of marine mammals to different types of underwater sound for context.

Consultee	Date/Document	Comment	Response
NRW	NRW Response 22.05.19 (CAS-84017-M9P0)	We have a particular concern about the collision risk figures presented for cetaceans (all of which are European Protected Species) and seals. Note that harbour porpoise, bottlenose dolphin and grey seal are qualifying features of several Special Areas of Conservation in Welsh waters. It is important to note that the evidence for the potential impacts of marine mammal collision with tidal devices with the potential to cause injury or fatalities is severely limited. We note that mitigation for collision risk is proposed by the use of monitoring systems (such as active sonar; passive acoustics; cameras) and deterrents such as Acoustic Deterrent Devices as part of an adaptive management plan. However, based on the information that we have seen so far and the evidence currently available to us regarding these methods, we cannot be fully confident that the proposed mitigation will be effective. As such we may not be able to conclude that significant adverse effects on the integrity of European protected sites could be ruled out without reasonable scientific doubt or that the project would not be detrimental to the favourable conservation status of European Protected Species. We may need to consider further measures as a fail-safe if the above mitigation fails, such as a shutdown of operations when a certain number of collisions occur, as part of the consent conditions. We note the ‘one dolphin scenarios’ presented on slide 38 of the Morlais Marine Mammal TWG 3rd Meeting presentation document and recommend that further consideration is given to an initial test phase of deployment of the scale given in the lower table, subject to us being satisfied with the predicted collision risk figures for the other cetacean and seal species with this approach. We acknowledge that this would generate up to 17.65MW, which is much less than the intended first phase of 40MW. A smaller test phase with reduced collision risk for cetacean and seal species could potentially offer a solution to allow progress if sufficient monitoring was put in place via an adaptive management plan to inform whether relevant Marine Licence conditions could be discharged before further devices were deployed. In addition, we wish to reiterate the advice from our EIA Scoping Opinion (paragraph 0.6 of Scoping opinion SC1804, issued on 11/07/18) that, without wishing to prejudice the HRA or consenting processes, should it not be possible to identify a package of measures that would avoid or mitigate the effects of the proposal and avoid adverse effects on the	Taking into account NRW’s comments, the collision risk assessments in the ES (**Section 12.6.4.4.1**) and information for the HRA (**Document MOR/RHDHV/DOC/0067**) are based on the less than one bottlenose dolphin collision risk scenarios. The assessments are based on indicative scenarios for the combination of different types of devices where the collision risk is predicted to be less than one bottlenose dolphin (based on the scenarios with the current maximum MW). Each stage of deployment would only progress based on these scenarios and that the regular reviewing of the monitoring and mitigation indicated that there was no increased collision risk. The approach will be to deploy to a level where the risk is less than one bottlenose dolphin. This deployment will then be monitored with mitigation, such as the use of ADDs if animals come too close to the tidal devices and arrays. The next phase of deployment would only proceed when a review of the monitoring and requirements for mitigation (e.g. how often ADDs were activated), indicates that there is no increased collisions risk. This would be done through the adaptive management and mitigation plan (EMMP) and in consultation with NRW. Therefore, the assessments, including the in-combination

Consultee	Date/Document	Comment	Response
		integrity of European protected sites it may be necessary to consider the proposal under Regulation 64 of the Conservation of Habitats and Species Regulations (“IROPI”).	assessment, is based on the scenarios for less than one bottlenose dolphin, as this would be the worst-case scenario. It is important to note that the output of the devices (MW) used in the assessments have been based on the current minimum rating, as a worst-case scenario and prior to deployment it is expected that the rating (MW) for the devices deployed could be higher for devices of the same or similar parameters. Further assessments will be conducted prior to deployment as part of the adaptive management and mitigation plan (EMMP). For information, indicative assessments for additional collision risk scenarios are presented in **Appendix 12.2** (**Volume III**).

12.4. METHODOLOGY

12.4.1. Study Area

46. Marine mammals are highly mobile and transitory in nature; therefore, it is necessary to examine species occurrence not only within the proposed MDZ, but also over the wider region. For each species of marine mammal, the following study areas have been defined based on the relevant Management Units (MUs), current knowledge and understanding of the biology of each species; taking into account the feedback received during consultation.

- Harbour porpoise Celtic and Irish Seas (CIS) MU;
- Bottlenose dolphin Irish Sea (IS) MU;
- Minke whale Celtic and Greater North Seas (CGNS) MU;
- Risso’s dolphin Celtic and Greater North Seas (CGNS) MU;
- Common dolphin Celtic and Greater North Seas (CGNS) MU;
- Grey seal South and West England and Wales MU and the OSPAR region; and
- Harbour seal in Wales and the OSPAR region.

47. MUs provide an indication of the spatial scales at which effects of plans and projects alone, and in-combination, need to be assessed for the key cetacean species in UK waters, with consistency across the UK (Inter-Agency Marine Mammal Working Group (IAMMWG), 2015). The study areas, MUs and reference populations used in the assessment have been determined based on the most relevant information and scale at which potential impacts from the proposed Project alone and cumulatively with other plans and projects.

48. The status and activity of marine mammals known to occur within or adjacent to the MDZ is considered in the context of regional population dynamics at the relevant scale, depending on the data available for each species and the extent of the agreed reference population.

12.4.2. Data Sources – Site-Specific Surveys and Reports

49. Marine mammal data for the MDZ have been collected by:

- Morlais Natural Power boat surveys data (visual surveys, shared platform with bird surveys): 24 boat surveys from November 2016 to October 2018 (**Appendix 11.1, Volume III**); and
- SEACAMS boat surveys data (visual and acoustic): 18 boat surveys from January 2015 to December 2016 (**Appendix 12.1, Volume III**).

12.4.2.1. Natural Power Surveys

50. Twenty-four surveys were conducted during two years of baseline marine mammal surveys of the Morlais Demonstration Zone (MDZ) between November 2016 and October 2018.

12.4.2.1.1. Survey Vessel

51. The surveys were all undertaken using the vessel Seekat C. The vessel is operated by SeeKat Marine Charters of Amlwch, north Anglesey. The SeeKat C is a Maritime and Coastguard Agency (MCA) Category 2 survey boat and has the following attributes:

- A forward-facing viewing platform with an unobstructed view;
- An observer eye height of greater than 5 m above sea level; and
- Capable of completing surveys at a speed of 5-15 knots (undertaken at 8-12 knots).

12.4.2.1.2. Survey Area

52. The surveyed area was designed to cover the whole of the MDZ (‘the Site’) plus a buffer area around the Site of 2 km (1.08nm) (the ‘survey area’). Note, however, that parts of the buffer on the east side actually encompass land.

53. The survey area was surveyed using 13 parallel transects, of varying length, orientated in a west-east direction. This transect orientation, being approximately perpendicular to the coast, ensured that each transect comprised a similar depth profile. Transects were spaced 0.92 km (0.5nm) apart, which is the minimum transect separation distance specified by boat-based survey guidelines (e.g. Camphuysen *et al*., 2004).

54. Whilst slightly under the recommended 15 transects for robust Distance analysis (Buckland *et al*., 2004), this spacing maximised survey coverage across the MDZ and 2 km buffer. The total length of all transects was 101.94 km (55.04nm). The location of the Site, together with the survey transects are illustrated in **Plate 12-1**.

12.4.2.1.3. Survey Timing

55. The surveys were scheduled to be undertaken on a monthly basis: i.e. one survey per calendar month for two years. On occasion, there were months where a survey was not possible due to poor weather or logistical constraints. Surveys were not undertaken in February, June or October 2017, or in September 2018. These surveys were completed as soon as possible in subsequent months to ensure that the full suite of 24 surveys were carried out within the two year period.

56. Each survey was carried out on a single day and took between five and six hours to complete. The direction along which transects were surveyed was alternated from north to south (Transect 1 to 13) and from south to north (Transect 13 to 1), to build temporal variation into the baseline dataset collected.

57. Surveys were largely undertaken during appropriate weather conditions, considered to be sea state three of less, swell height of <0.5m or less, and visibility of more than 500m.

58. For further details on survey effort, survey methods, data analysis and survey results see **Appendix 11.1** (**Volume III**).

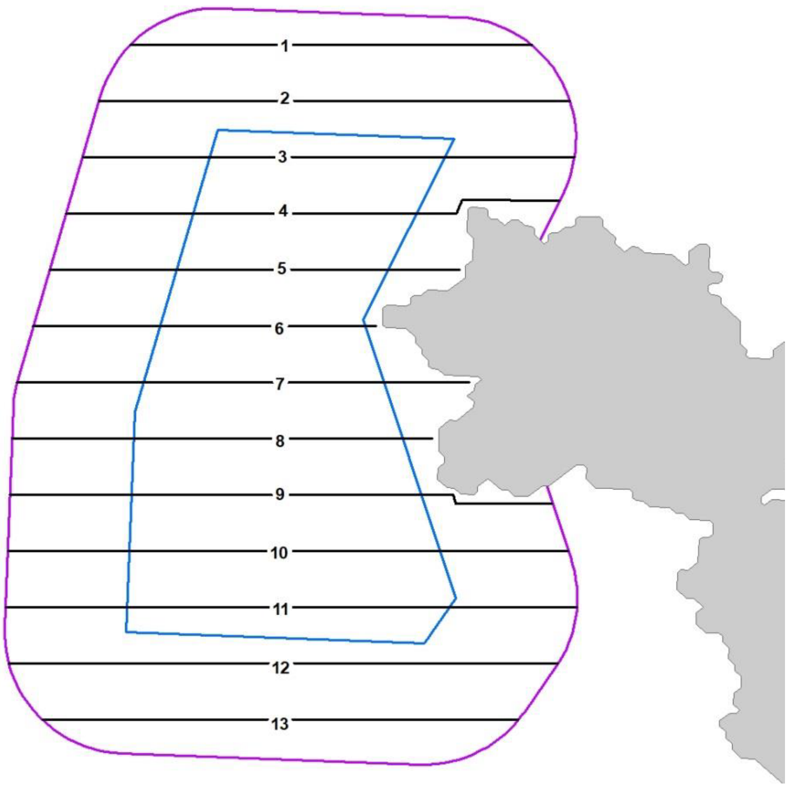

Plate 12-1 Location of Morlais Demonstration Zone (MDZ), the 2 km buffer survey area and transect layout used for Natural Power surveys (Source: Natural Power, 2018)

12.4.2.2. SEACAMS Surveys

59. Eighteen surveys were conducted between January 2015 and December 2016.

12.4.2.2.1. Survey Area and Design

60. The survey site (**Plate 12-2**) covers an area that includes the West Anglesey Demonstration Zone (WADZ) boundary, now the MDZ, as well as a buffer zone. A series of 10 zig zag transect lines were designed to provide even and maximum coverage of the survey area (**Plate 12-2**). Spacing between transect lines is approximately one kilometre. The orientation of the lines were designed so that transects cut across the predominant current direction as shown by a SEACAMS hydrodynamic model in order to minimise fluctuations in speed over ground caused by strong current speeds.

61. Surveys were conducted on days where predominantly Beaufort Sea state was force two or less. These are known to be favourable conditions to collect visual data on harbour porpoise, the target species. The aimed intensity of surveys was one per month, where 1-2 transects were completed at an average speed of 10 knots. Surveys were conducted in all seasons.

12.4.2.2.2. Survey Vessel

62. The surveys were also all undertaken using the 11 metre catamaran ‘Seekat C’, equipped with twin 280hp diesel engines was chartered for surveys. On the roof of the vessel are two purpose-built platforms for up to four observers (two primary and two independent observers). The primary observer platform reaches an eye height of approximately 4.5 metres with slight fluctuations depending on observer height. The eye height of the independent observer platform is approximately 5.5 metres. A wind breaker between the two platforms is used during surveys allowing independence between observers.

63. For further details on survey effort, visual and acoustic survey methods, data analysis and survey results see **Appendix 12.1**.

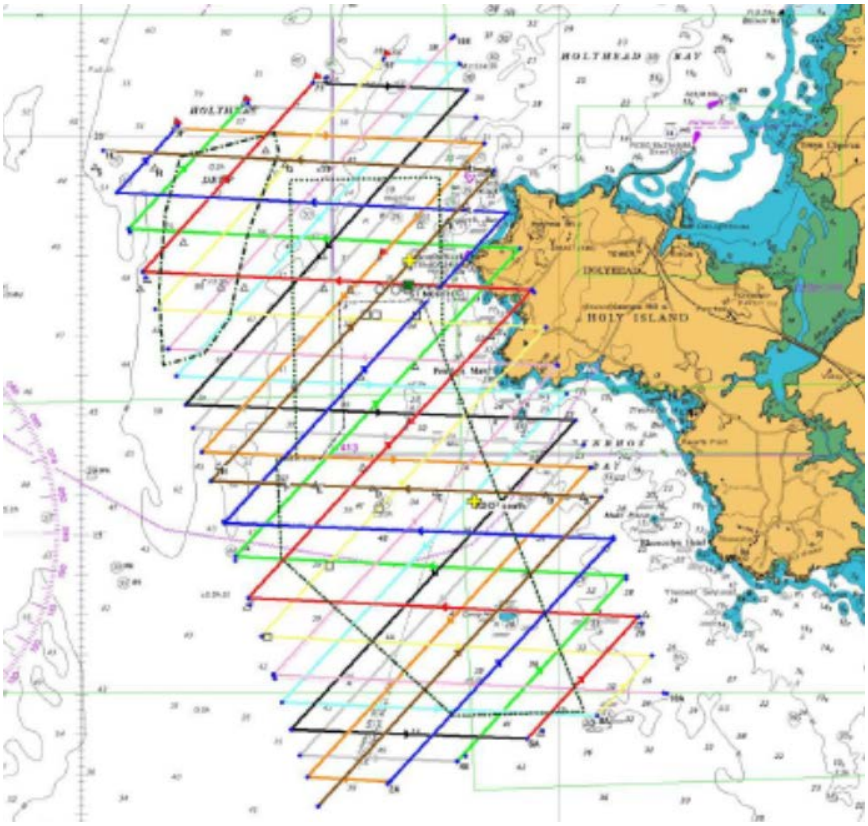

Plate 12-2 SEACAMS survey area and transect lines. One zig zag transect is represented by each colour

12.4.3. Data Sources – Desk Study

64. In addition to the site-specific surveys, a range of other relevant data sources and information has been reviewed to provide information on the marine mammal species that could be present in and around the proposed Morlais site, this includes, but is not limited to:

- Small Cetaceans in the European Atlantic and North Sea (SCANS-III) data (Hammond *et al*., 2017).
- ObSERVE aerial surveys (Rogan *et al*., 2018);
- Sea Watch Foundation sightings (Sea Watch Foundation, 2019);
- Management Units (MUs) for cetaceans in UK waters (Inter-Agency Marine Mammal Working Group (IAMMWG), 2015).
- The identification of discrete and persistent areas of relatively high harbour porpoise density in the wider UK marine area (Heinänen and Skov, 2015).
- Revised Phase III data analysis of Joint Cetacean Protocol (JCP) data resources (Paxton *et al*., 2016).
- UK seal at sea density estimates and usage maps (Russell *et al*., 2017).
- Special Committee on Seals (SCOS) annual reporting of scientific advice on matters related to the management of seal populations (SCOS, 2017).
- All relevant NRW reports, for example, Clarke *et al*. (2018). Grey Seal (*Halichoerus grypus*) Pup Production and Distribution in North Wales.

- Atlas of the Marine Mammals of Wales. Countryside Council for Wales (CCW) Monitoring Report No. 68 (Baines and Evans, 2012).
- UK Offshore Energy Strategic Environmental Assessment. OWESEA3 March 2016 (Department of Energy and Climate Change (DECC), 2016).
- Minesto Deep Green Holyhead Deep Project Environmental Statement and Habitats Regulations Assessment Report (Minesto, 2016).
- Horizon Wylfa Newydd Power Station baseline information, Environmental Statement and information for Habitats Regulations Assessment (Horizon Nuclear Power (HNP), 2018a, b).

12.4.4. Impact Assessment Methodology

65. The general EIA methodology is set out within **Chapter 5, EIA Methodology**. In principle, a matrix approach has been used to assess impacts following best practice and EIA guidance. Each potential impact has been identified using expert judgement and through consultation with NRW. An assessment of the significance has then made based on the sensitivity, value and magnitude of effect.

12.4.4.1. Sensitivity

66. The sensitivity of a receptor is determined through its ability to accommodate change and on its ability to recover if it is negatively affected. The sensitivity level of marine mammals to each type of impact is justified within the impact assessment and is dependent on the following factors:

- Adaptability – The degree to which a receptor can avoid or adapt to an effect;
- Tolerance – The ability of a receptor to accommodate temporary or permanent change without a significant adverse effect;
- Recoverability – The temporal scale over and extent to which a receptor will recover following an effect; and
- Value – A measure of the receptor's importance and rarity (as reflected in the species conservation status and legislative importance, see **section 12.4.4.2**).

67. The sensitivity to potential impacts of lethality, physical injury, auditory injury or hearing impairment, as well as behavioural disturbance or auditory masking will be considered for each species, using available evidence including published data sources. **Table 12-6** defines the levels of sensitivity and what they mean for the receptor.

Table 12-6 Definitions of sensitivity levels for marine mammals

Sensitivity	Definition
High	Individual receptor has very limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Medium	Individual receptor has limited capacity to avoid, adapt to, accommodate or recover from the anticipated impact.
Low	Individual receptor has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact.

Sensitivity	Definition
Negligible	Individual receptor is generally tolerant to and can accommodate or recover from the anticipated impact.

12.4.4.2. Value

68. In addition, the 'value' of the receptor forms an important element within the assessment, for instance, if the receptor is a protected species. It is important to understand that high value and high sensitivity are not necessarily linked. A receptor could be of high value (e.g. an Annex II species), but have a low or negligible physical/ecological sensitivity to an effect. Similarly, low value does not equate to low sensitivity and is judged on a receptor by receptor basis.

69. In the case of marine mammals, a large number of species fall within legislative policy; all cetaceans in UK waters are EPS and, therefore, are internationally important. Harbour porpoise, bottlenose dolphin, grey seal and harbour seals are also afforded international protection through the designation of Natura 2000 sites. As such, all species of marine mammal can be considered to be of high value.

70. The value will be considered, where relevant, as a modifier for the sensitivity assigned to the receptor, based on expert judgement. **Table 12-7** provides definitions for the value afforded to a receptor based on its legislative importance.

Table 12-7 Definitions of value levels for marine mammals

Value	Definition
High	Internationally or nationally important
Medium	Regionally important or internationally rare
Low	Locally important or nationally rare
Negligible	Not considered to be or particular important or rare

12.4.4.3. Magnitude

71. The significance of the potential impacts is also based on the intensity or degree of impact to the baseline conditions and is categorised into four levels of magnitude: high; medium; low; or negligible, as defined in **Table 12-8**.

72. The thresholds defining each level of magnitude of effect for each impact have been determined using expert judgement, current scientific understanding of marine mammal population biology and JNCC *et al*. (2010) draft guidance on disturbance to EPS species. The magnitude of each effect is calculated or described in a quantitative or qualitative way within the assessment.

73. The number of animals that can be 'removed' from a population through injury or disturbance will vary between species, but is largely dependent on the growth rate of the population; populations with low growth rates can sustain the removal of a smaller proportion of the population. The JNCC *et al*. (2010) draft guidance provides some indication on how many animals may be removed from a population without causing detrimental effects to the population at FCS. The JNCC *et al*. (2010) draft guidance also provides limited consideration of temporary effects, with guidance reflecting consideration of permanent displacement. As such this guidance has been considered in defining the thresholds for magnitude of effects.

74. Temporary effects are considered to be of medium magnitude at greater than 5% of the reference population being affected within a year. JNCC *et al*. (2010) draft guidance considered 4% as the maximum potential growth rate in harbour porpoise, and the ‘default’ rate for cetaceans. Therefore, beyond natural mortality, up to 4% of the population could theoretically be permanently removed before population growth would be halted. In assigning 5% to a temporary impact in this assessment, consideration is given to uncertainty of the individual consequences of temporary disturbance.

75. Permanent effects to greater than 1% of the reference population being affected within a year are considered to be high magnitude in this assessment. The assignment of this level is informed by the JNCC *et al*. (2010) draft guidance (suggesting 4% as the ‘default maximum growth rate for cetaceans) but also reflects the large amount of uncertainty in the potential individual and population level consequences of permanent effects.

Table 12-8 Definitions of magnitude levels for marine mammals

Value	Definition
High	Permanent irreversible change to exposed receptors or feature(s) of the habitat which are of particular importance to the receptor. Assessment indicates that more than 1% of the reference population are anticipated to be exposed to the effect. OR Long-term effect for 10 years or more (but not permanent, e.g. limited to lifetime of the project). Assessment indicates that more than 5% of the reference population are anticipated to be exposed to the effect. OR Temporary effect (limited to phase of development or Project timeframe) to the exposed receptors or feature(s) of the habitat which are of particular importance to the receptor. Assessment indicates that more than 10% of the reference population are anticipated to be exposed to the effect.
Medium	Permanent irreversible change to exposed receptors or feature(s) of the habitat of particular importance to the receptor. Assessment indicates that between 0.01% and 1% of the reference population anticipated to be exposed to effect. OR Long-term effect for 10 years or more (but not permanent, e.g. limited to lifetime of the project). Assessment indicates that between 1% and 5% of the reference population are anticipated to be exposed to the effect. OR Temporary effect (limited to phase of development or Project timeframe) to the exposed receptors or feature(s) of the habitat which are of particular importance to the receptor. Assessment indicates that between 5% and 10% of the reference population anticipated to be exposed to effect.
Low	Permanent irreversible change to exposed receptors or feature(s) of the habitat of particular importance to the receptor. Assessment indicates that between 0.001% and 0.01% of the reference population anticipated to be exposed to effect. OR Long-term effect for 10 years or more (but not permanent, e.g. limited to lifetime of the project).

Value	Definition
	Assessment indicates that between 0.01% and 1% of the reference population are anticipated to be exposed to the effect. OR Intermittent and temporary effect (limited to phase of development or Project timeframe) to the exposed receptors or feature(s) of the habitat which are of particular importance to the receptor. Assessment indicates that between 1% and 5% of the reference population anticipated to be exposed to effect.
Negligible	Permanent irreversible change to exposed receptors or feature(s) of the habitat of particular importance to the receptor. Assessment indicates that 0.001% or less of the reference population anticipated to be exposed to effect. OR Long-term effect for 10 years or more (but not permanent, e.g. limited to lifetime of the project). Assessment indicates that 0.01% or less of the reference population are anticipated to be exposed to the effect. OR Intermittent and temporary effect (limited to phase of development or Project timeframe) to the exposed receptors or feature(s) of the habitat which are of particular importance to the receptor. Assessment indicates that 1% or less of the reference population anticipated to be exposed to effect.

12.4.4.4. Impact Significance

76. Following the identification of receptor sensitivity and the magnitude of the effect, the impact significance is determined using expert judgement. The probability of the impact occurring is also considered in the assessment process. If doubt exists concerning the likelihood of occurrence or the prediction of an impact, a precautionary approach is taken to assign a higher level of probability to adverse effects.

77. The matrix (provided in **Table 12-9**) is used as a framework to aid determination of the impact assessment. Definitions of impact significance are provided in **Table 12-10**. For the purposes of this assessment and specifically the marine mammal assessment, major and moderate impacts are considered to be significant. However, whilst minor impacts would not be considered significant in their own right, they may contribute to significant impacts cumulatively or through inter-relationships.

Table 12-9 Impact significance matrix

		Negative Magnitude				Beneficial Magnitude			
		High	Medium	Low	Negligible	Negligible	Low	Medium	High
Sensitivity	High	Major	Major	Moderate	Minor	Minor	Moderate	Major	Major
	Medium	Major	Moderate	Minor	Minor	Minor	Minor	Moderate	Major
	Low	Moderate	Minor	Minor	Negligible	Negligible	Minor	Minor	Moderate
	Negligible	Minor	Negligible	Negligible	Negligible	Negligible	Negligible	Negligible	Minor

Table 12-10 Definitions of impact significance for marine mammals

Value	Definition
High	Very large or large changes (either adverse or beneficial) to a receptor (or receptor group), which is important at a population (national or international) level because of the contribution to achieving national or regional objectives, or, a change expected to result in exceedance of statutory objectives and / or breaches of legislation.
Medium	Intermediate or large changes (either adverse or beneficial) to a receptor (or receptor group), which may be an important consideration at national or regional population level. Potential to result in exceedance of statutory objectives and / or breaches of legislation.
Low	Small changes (either adverse or beneficial) to a receptor (or receptor group), which may be raised as local issues but is unlikely to be important at a regional population level.
Negligible	No discernible change in receptor (or receptor group).

78. If mitigation is required or proposed, the assessment will also take into the mitigation to provide the post-mitigation residual impact. If the impact does not require mitigation (or none is possible) the residual impact will remain the same.

12.4.5. Cumulative Impact Assessment

79. The cumulative impact assessment (CIA) identifies areas where the predicted impacts of the construction, operation, maintenance and decommissioning of the proposed Project could interact with impacts from different plans or projects within the same region and impact sensitive receptors.

80. For this assessment, the stages of project development have been considered within the cumulative impact assessment. This was based on guidance issued by JNCC and Natural England in September 2013 and the Planning Inspectorate (2015) Advice Note 17. The assessment therefore takes into consideration: built and operational projects; projects under construction; projects that have been consented (but construction has not yet commenced); projects that have an application submitted to the appropriate regulatory body that have not yet been determined; projects that the regulatory body are expecting to be submitted for determination (e.g. projects listed under the Planning Inspectorate programme of projects); and projects that have been identified in relevant strategic plans or programmes.

81. The types of plans and projects taken into consideration, where relevant, include:

- Other marine renewable (wave and tidal) developments;
- Offshore windfarms;
- Aggregate extraction and dredging;
- Licenced disposal sites;
- Shipping and navigation;
- Sub-sea cables and pipelines;
- Port and harbour developments;
- Coastal developments; and
- Oil and gas development and operation, including seismic surveys.

82. The CIA is a two-part process in which an initial list of potential projects is identified with the potential to interact with the proposed Project based on the mechanism of interaction and spatial

extent of the reference population for each marine mammal receptor. The list of projects is then refined based on the level of information available for this list of projects to enable further assessment.

83. The plans and projects screened in to the CIA are:

- Located in the relevant marine mammal population reference area (defined for individual species in the assessment sections); and
- Have potential construction, operational and decommissioning activities which could result in potential cumulative impacts with the construction, operation and decommissioning of the proposed Morlais project.

84. The CIA will consider projects, plans and activities which have sufficient information available to undertake the assessment. Insufficient information will preclude a meaningful quantitative assessment, and it is not appropriate to make assumptions about the detail of future projects in such circumstances.

85. Commercial fisheries have the potential to cause a cumulative impact on marine mammals, through both the direct impact of by-catch, the indirect impact through the loss of marine mammal prey species (from commercial fisheries) and the disturbance from underwater noise (from vessel presence). However, by-catch by commercial fisheries is recognised as a historic and continuing cause of marine mammal mortality and will therefore be a factor in shaping the size of the current Management Unit (MU) populations. The available prey has also been influenced by historic and continuing commercial fishing.

86. Noise and disturbance from vessels associated with established activities such as ferry routes, commercial shipping routes and commercial fisheries, are also considered to be part of the baseline conditions.

87. This approach is in accordance with the Planning Inspectorate Advice Note 17 Cumulative Effects Assessment, which states that:

“Where other projects are expected to be completed before construction of the proposed NSIP and the effects of those projects are fully determined, effects arising from them should be considered as part of the baseline”.

12.4.6. Transboundary Impact Assessment

88. The potential for transboundary impacts has been addressed by considering the reference populations, MUs, seal telemetry and potential linkages to non-UK sites.

89. The assessment of the effect on the integrity of the transboundary European sites as a result of impacts on the designated marine mammal populations will be undertaken and presented in the Report to inform the HRA.

12.5. EXISTING ENVIRONMENT

90. A review of the Atlas of Marine Mammals of Wales indicates that nineteen marine mammal species have been recorded in Welsh waters since 1990 (Baines and Evans, 2012). The most

regular visitors are harbour porpoise, bottlenose dolphin, grey seal, common dolphin, Risso's dolphin and minke whale. Species recorded more rarely include fin whale, sei whale and humpback whale. Grey seal are also regularly recorded around Wales (Baines and Evans, 2012; SCOS, 2017).

91. The Sea Watch Foundation collate volunteer cetacean sightings from around the UK's coastline. The most recent sightings between October 2018 and February 2019 from around the Welsh coastline have recorded predominantly bottlenose dolphin and harbour porpoise, while other cetacean species that have been sighted included Risso's dolphin and common dolphin (Sea Watch Foundation, 2019). Around Anglesey, the majority of sightings have been of harbour porpoise, bottlenose dolphin, Risso's dolphin and common dolphin (Sea Watch Foundation, 2019).

92. A large-scale survey for cetaceans in European Atlantic waters was conducted in summer 2016 (SCANS-III) in all European shelf waters (Hammond *et al*., 2017). The survey was split into survey areas, or blocks, with the MDZ being located within the SCANS-III survey block E, which recorded harbour porpoise, bottlenose dolphin, Risso's dolphin and minke whale to be present (Hammond *et al*., 2017).

93. The available data from the site specific survey (**Section 12.4.2**) and other data sources (**Section 12.4.3**), indicates that marine mammal species that could be present in and around the MDZ are:

- Harbour porpoise;
- Bottlenose dolphin;
- Risso's dolphin;
- Common dolphin;
- Minke whale;
- Grey seal; and
- Harbour seal.

94. The marine mammal species included in the assessment were agreed with NRW at the second marine mammal technical working group (TWG) meeting in February 2019. **Section 12.5.10** provides a summary of the relevant density estimates and reference populations used in the assessments.

12.5.1. Harbour porpoise

12.5.1.1. Distribution and Occurrence

95. Harbour porpoise distribution is generally restricted to the temperate and sub-arctic waters of the Northern Hemisphere, mainly on the continental shelf at depths of 20-200m and primarily within water temperatures ranging from 11 to 14^{o}C (DECC, 2016; Reid *et al*., 2003).

96. Harbour porpoise are widely distributed throughout the Celtic and Irish Seas during most months of the year (Reid *et al*., 2003; Mackey *et al*., 2004; Baines and Evans, 2012; Hammond *et al*., 2013, 2017; Rogan *et al*., 2018). Their occurrence is not evenly distributed in Welsh waters with

apparent hotspots at the south-west coast of the Lleyn Peninsula, southern Cardigan Bay, in the vicinity of Strumble Head and the west and north Pembrokeshire Coast and Islands (Skomer and Ramsey) and in the Bristol Channel off the south coast of Wales around the Gower Peninsula and in Swansea Bay (Baines and Evans, 2012).

97. Harbour porpoise are typically widely distributed throughout Cardigan Bay, with detections in both inshore and offshore waters. Harbour porpoise clusters were observed in the southern part of Cardigan Bay SAC around Cemaes Head, Pembrokeshire, and harbour porpoise are regularly spotted offshore in both Cardigan Bay and Pen Llŷn a'r Sarnau SACs (Feingold and Evans, 2014b).

98. Localised hotspots also appear to exist off the north and north-west coast of Anglesey, in particular around Point Lynas and South Stack, including Holyhead Deep (Baines and Evans, 2012; Evans *et al*., 2015). Harbour porpoise are likely to be present at these locations throughout the year, with little seasonal variation (Baines and Evans, 2012; Evans *et al*., 2015).

99. During the site-specific surveys for the Wylfa Newydd Development Area, harbour porpoise were the most frequently reported cetacean (HNP, 2018a). The sightings were generally concentrated to the east of the Wylfa Newydd Development Area, in areas in the vicinity of Middle Mouseand Point Lynas. The Vantage Point (VP) surveys indicated that the survey area covered from Wylfa Head, had the highest number of individuals recorded.

100. Heinänen and Skov (2015) provided detailed analyses of 18 years of Joint Cetacean Protocol (JCP) survey data. The model results for the Celtic and Irish Seas indicate that most important factors for probability of presence of harbour porpoise in this MU during summer are increasing current speeds up to 0.4m/s and with increasing eddy activity. In winter, the same response to current speed is observed, although there are lower probabilities with high current speeds (Heinänen and Skov, 2015). The responses to water depth indicate that high densities of harbour porpoise are associated with the shallowest areas (areas shallower than 40m) in summer and high probability of presence in the same areas in winter. During summer, high densities are often associated with sandy-gravelly sediments, with rather low densities in muddy areas (Heinänen and Skov, 2015).

101. The Heinänen and Skov (2015) study identified several persistent high density areas off Wales. Three coastal areas off west Wales (Pembrokeshire and Cardigan Bay), and north-west Wales (Anglesey, Lleyn Peninsula), and part of the Bristol Channel (Camarthen Bay). The distribution of harbour porpoise during the site-specific surveys of the MDZ and 2 km buffer conducted by Natural Power (**Appendix 11.1**), as calculated by the Distance analysis, indicates that the greatest abundance of porpoise occurred in the north of the survey area (**Plate 12-3**).

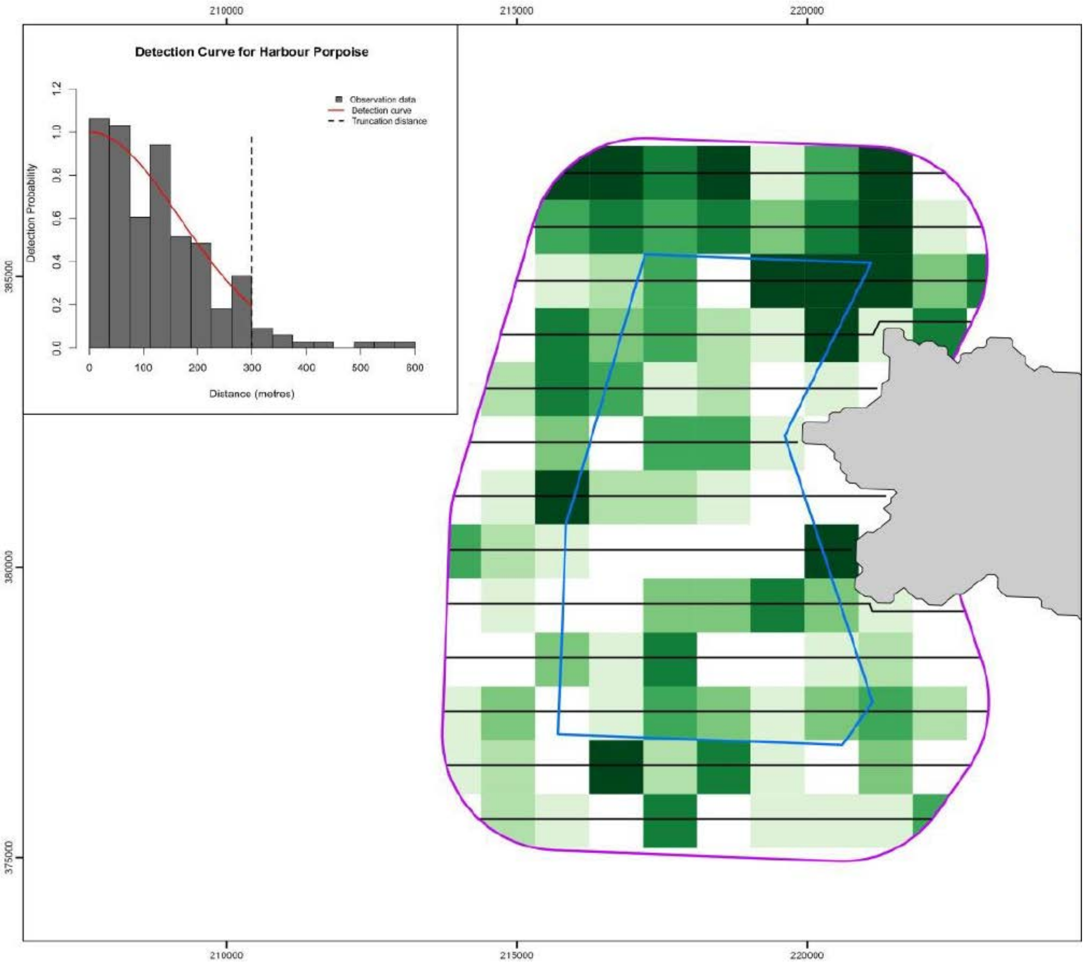

Plate 12-3 Density of harbour porpoise calculated using Distance analysis (and associated detection curve) from Natural Power site specific surveys

12.5.1.2. Abundance and Density Estimates

12.5.1.2.1. Celtic and Irish Seas Management Unit

102. Harbour porpoise within the eastern North Atlantic are generally considered to be part of a continuous biological population that extends from the French coastline of the Bay of Biscay to northern Norway and Iceland (Tolley and Rosel, 2006; Fontaine *et al*., 2007, 2014; IAMMWG, 2015). However, for conservation and management purposes, it is necessary to consider this population as smaller Management Units (MUs). MUs provide an indication of the spatial scales at which effects of plans and projects alone, and in-combination, need to be assessed for the key cetacean species in UK waters, with consistency across the UK (IAMMWG, 2015).

103. The Inter-Agency Marine Mammal Working Group (IAMMWG) defined three MUs for harbour porpoise: The North Sea (NS); West Scotland (WS) and the Celtic and Irish Sea (CIS) (comprising ICES area VI and VII, except VIId). The MDZ is located in the Celtic and Irish Seas MU (**Plate 12-4**), which has an estimated harbour porpoise abundance of 104,695 (CV = 0.32; 95% CI = 56,774-193,065; IAMMWG, 2015), this was based on the SCANS-II survey (Hammond *et al*., 2013) and CODA surveys (Macleod *et al*., 2009).

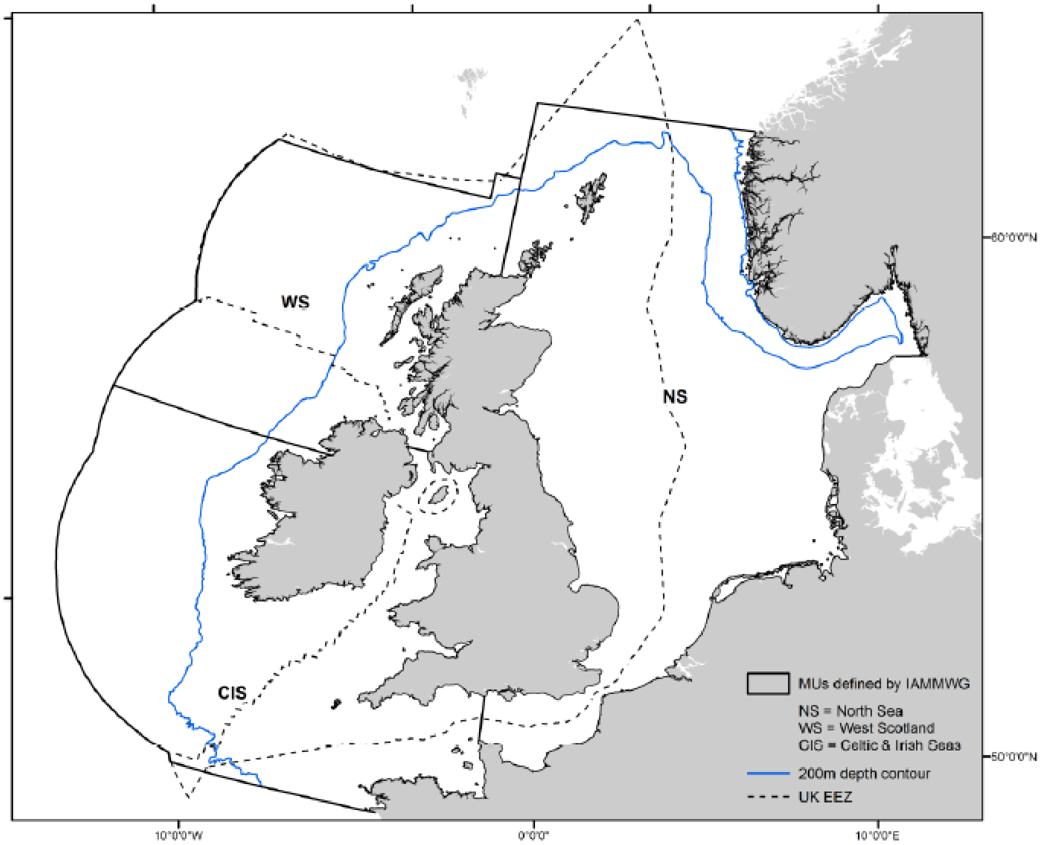

Plate 12-4 Harbour Porpoise Management Units (Source: IAMMWG, 2015)

104. Information provided by NRW (NRW comments on 1st marine mammal TWG meeting), indicates that the abundance estimate for the Celtic and Irish Seas MU based on the original SCANS-II (2005) data was 107,384 (CV = 0.30) and the abundance estimate based on the revised SCANS-II (2005) data was 98,807 (CV = 0.30; 95% CI = 57,315-170,336). The abundance estimate for the Celtic and Irish Seas MU based on the SCANS-III and ObSERVE survey was not available at the time of writing. It was therefore agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019, that the published IAMMWG (2015) abundance estimate for the Celtic and Irish Seas MU was the most appropriate to use in the assessments.

105. For the assessments, the CIS MU has been used as the reference population. This is appropriate to take into account the wide range and distances covered by harbour porpoise. As stated in the North Anglesey Marine / Gogledd Môn Forol SAC Selection Assessment Document "*as a wide-ranging species, the animals within the North Anglesey Marine / Gogledd Môn Forol site cannot be considered isolated in relation to the rest of the population. Animals within the site are part of the wider MU population*" (JNCC and NRW, 2017).

12.5.1.2.2. Joint Cetacean Protocol (JCP) Data

106. The Revised Phase-III Data Analysis of the Joint Cetacean Protocol (JCP) (Paxton *et al*., 2016) and The Identification of Discrete and Persistent Areas of Relatively High Harbour Porpoise Density in the Wider UK Marine Area (Heinänen and Skov, 2015) analyse harbour porpoise abundance and distributions in UK waters. Both projects used numerous data sources collated by the JCP.

107. The two projects, through the use of complex modelling produced distribution maps and estimates of density for harbour porpoise in UK waters. The JCP report specifically aimed to examine abundance and changes in abundance which can be used to assist in environmental impact assessments (Paxton *et al*., 2016). The analyses helped identify discrete and persistent areas of high harbour porpoise density in the UK marine area using habitat mapping; the aim of this project was to assist in the identification of potential harbour porpoise SACs (Heinänen and Skov, 2015).

108. The results of the two projects produced broadly similar modelled densities of harbour porpoise; however, derivation of the results using different modelling approaches resulted in some key differences (JNCC, 2016). For example, the Heinänen and Skov (2015) report uses associations between observed numbers and habitat characteristics and is therefore more likely to provide a realistic picture of harbour porpoise density where effort is low (Paxton *et al*., 2016).

109. As such, JNCC have provided some advice on the use of the outputs in analyses for environmental impact assessments. JNCC (2016) concluded that the Heinänen and Skov (2015) density surfaces better represent the expected distribution and abundance of harbour porpoise for any given area of interest and should, therefore, be used preferentially. The densities from the Heinänen and Skov (2015) report are not currently available for wider use and, in the interim, JNCC advice that the JCP Phase-III density surfaces for harbour porpoise may be used.

110. The revised JCP Report (2016) defines a set of Developer Areas of which are important areas for the development of offshore renewable energy. The closest developer area for harbour porpoise is the Irish Sea Developer Area (with an estimate of 2.2-5.9% of CIS reference population). Other Developer Areas included within the MU are Isle of Wight (0.2-0.8% of CIS MU), Atlantic Array (7.9-18.6% of CIS MU), Strangford Loch (0.2-0.7% of CIS MU) and Solway Firth (0.8-2.2% of CIS MU) (Paxton *et al*., 2016).

12.5.1.2.3. SCANS Data

111. In July 2005, SCANS-II surveyed the entire European Atlantic continental shelf to generate robust estimates of abundance for harbour porpoise and other cetacean species (shown on **Plate 12-5**). For the entire SCANS-II survey area, harbour porpoise abundance in the summer of 2005 was estimated to be 375,358 (CV = 0.197; Hammond *et al*., 2013). The SCANS-II survey estimated that the abundance of harbour porpoise in survey block O (an area of 45,417 km^2), which is located in the Irish Sea and includes the MDZ, was 15,230 individuals (CV = 0.35) and the density was estimated to be 0.335 harbour porpoise per km2 (CV = 0.35) (Hammond *et al*., 2013).

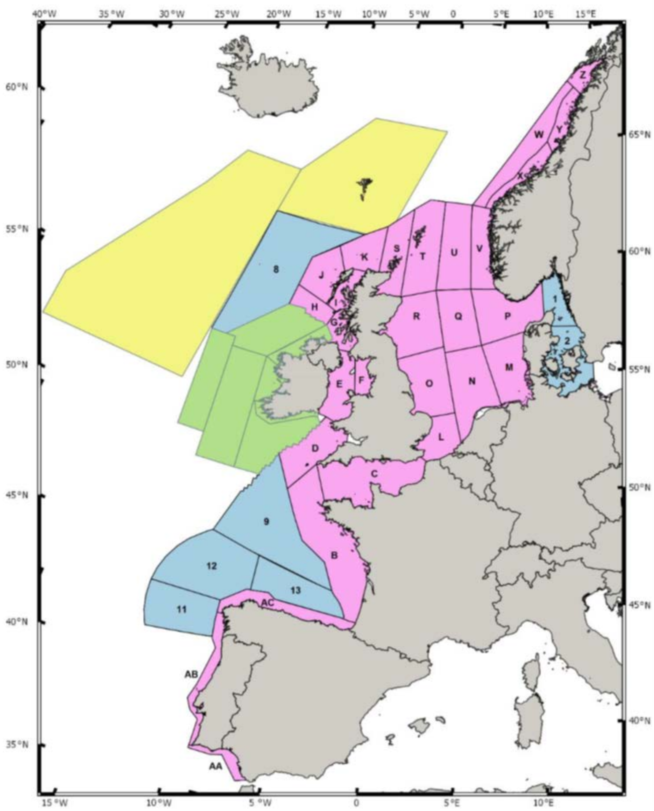

Plate 12-5 Area covered by SCANS-III and adjacent surveys[2] (Source: Hammond *et al*., 2017)

112. SCANS-III in the summer of 2016 surveyed all European Atlantic waters from the Strait of Gibraltar in the south to 62°N in the north and extending west to the 200 nautical miles (nm) limits of all EU Member States (Hammond *et al*., 2017). The survey area was not the same as for SCANS-II. For the entire SCANS-III survey area, harbour porpoise abundance in the summer of 2016 was estimated to be 466,569 with an overall estimated density of 0.381/ km^2 (CV = 0.154; 95% CI = 345,306-630,417; Hammond *et al*., 2017).

113. Estimates for harbour porpoise in the Celtic and Irish Seas ICES Assessment Unit (partial coverage only) during the SCANS-III survey was an abundance of 26,700 and density of 0.11/ km^2 (CV = 0.25; 95% CI = 16,055 – 42,128; Hammond *et al*., 2017).

114. The SCANS-III survey estimated that the abundance of harbour porpoise in survey block E (**Plate 12-5**; surface area of 34,870 km^2), which is located in the Irish Sea and includes the MDZ, was 8,320 individuals and the density was estimated to be 0.239 harbour porpoise per km^2, with a mean group size of 1.31 (CV = 0.28; 95% CI = 4,643 – 14,354; Hammond *et al*., 2017).

---

[2] SCANS-III areas = pink lettered blocks were surveyed by air; blue numbered blocks were surveyed by ship. Adjacent survey = blocks coloured green to the south, west and north of Ireland which were surveyed by the Irish ObSERVE project and blocks coloured yellow which were surveyed by the Faroe Islands as part of the North Atlantic Sightings Survey in 2015

In the adjacent area, survey block F (**Plate 12-5**; surface area of 12,322 km^2), the estimated abundance was 1,056 harbour porpoise, with an estimated density of 0.086/ km^2 and mean group size of 1.00 (CV = 0.38; 95% CI = 342-2,010; Hammond *et al*., 2017).

12.5.1.2.4. ObSERVE Data

115. Extensive aerial surveys of Ireland's offshore waters (ObSERVE surveys) were conducted in the summer and winter of 2015 and 2016, with additional surveys conducted in inshore/coastal areas in the summer and winter of 2016. The study area covered waters overlying and beyond Ireland's continental shelf and was divided into five survey strata in 2015, with three smaller inshore strata added in 2016 (**Plate 12-6**). Within each stratum, two zig-zag transects were surveyed, designed to provide equal coverage probability (Rogan *et al*., 2018).

116. During the surveys, harbour porpoises were recorded over a large spatial area during the summer months, but a more coastal distribution was indicated in winter. Harbour porpoises were more commonly sighted in summer, with overall harbour porpoise abundance estimates of 35,975 individuals in summer (CV: 0.09) and 20,571 in winter (CV: 0.23) (Rogan *et al*., 2018).

117. The ObSERVE aerial surveys provide density estimates for the Irish Sea off the Irish Coast (Rogan *et al*., 2018). For stratum 5 (**Plate 12-6**), which covered the east coast of Ireland, the density estimates were 0.696 and 1.046 harbour porpoise per km^2 during the summer 2015 and 2016 periods, respectively; and during the winter periods were 0.867 and 0.924 harbour porpoise per km^2 in 2015 and 2016, respectively (as provided in **Section 12.5.1.2.7**).

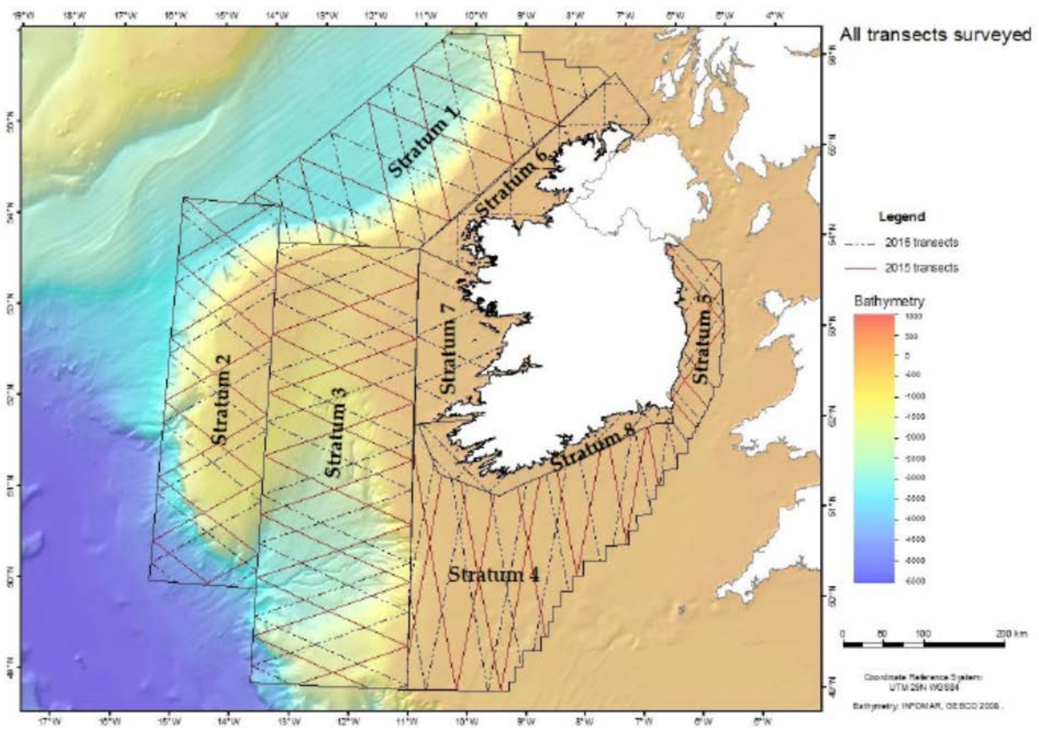

Plate 12-6 ObSERVE aerial transect lines flown in summer and winter 2015 and 2016 in relation to bathymetry (Source: Rogan *et al*., 2018)

12.5.1.2.5. Cardigan Bay

118. Harbour porpoise abundance estimates for the whole of Cardigan Bay between 2011 and 2013 have more than halved over the three years with an estimated 1074 in 2011, 565 in 2012 and 410 individuals in 2013 (Feingold and Evans, 2014b).

119. However, within Cardigan Bay SAC, harbour porpoise abundance estimates have changed little over the years, the only exception being in 2011 (**Plate 12-7**). The relatively high estimate in 2011 (340), reflects the very high CV due to low effort coverage, and the number of actual observations was low (n=20) whereas the estimates for 2012-13 are similar to those obtained in earlier years (2005-07).

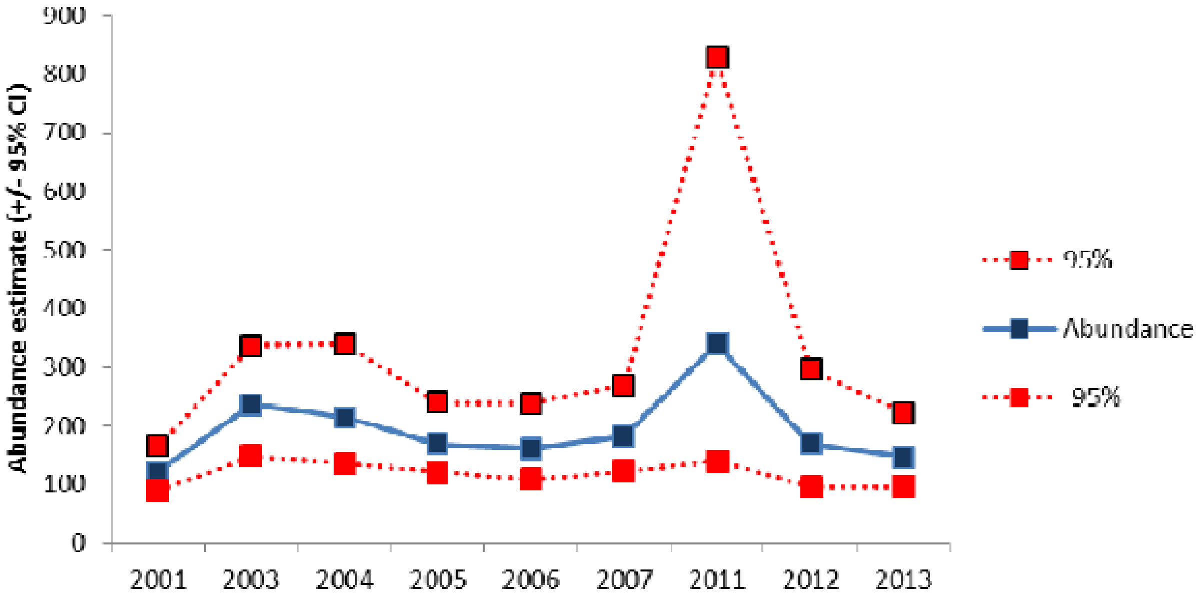

Plate 12-7 Abundance estimates of harbour porpoise in Cardigan Bay SAC, 2001-13 (Source: Feingold and Evans, 2014b)

12.5.1.2.6. North Anglesey Survey Data

120. Two dedicated studies of the harbour porpoise population around the north coast of Anglesey have been undertaken that cover some of the MDZ.

121. Shucksmith *et al*. (2009) conducted dedicated harbour porpoise surveys between 2002 and 2004 covering an area of approximately 489 km^2 extending from the east of Point Lynas to the west of South Stack on the north coast of Anglesey. In the three year study, visual and acoustic methods were used to detect the animals along 31 transects extending out from the shore between May and September. Shucksmith *et al*. (2009) assumed a g(0) of 1, where g(0) is the probability of detecting an animal on track line during the survey. If all animals were detected then g(0) would be 1, if half the animals were missed (e.g. they were under the water and not surfacing) then g(0) would be 0.5. In reality the g(0) for harbour porpoise is never as high as 1, so the Shucksmith *et al*. (2009) data likely represents an underestimate for this species. Shucksmith *et al*. (2009) estimated that the minimum number of harbour porpoise off the north

coast of Anglesey was 309 individuals (CV = 0.20), with an estimated density of 0.63 individuals per km^2. When g(0) is 0.5 is applied to the data, based on a precautionary scenario that half of the harbour porpoise were submerged, the estimated maximum abundance is 618 individuals, with a density estimate of 1.26 individuals per km^2.

122. The harbour porpoise study area used by Shucksmith *et al*. (2009) was split in to five sectors: South Stack (SS); Holyhead Harbour (HB); Carmel Head (CH); Middle Mouse (MM); and Point Lynas (PL). The Morlais Development Zone is located in the South Stack sector, where the estimated abundance was 207 harbour porpoise with an estimated density of 2.54/ km^2, based on g(0) is 0.5. However, it is important to note that 75% of all detections were made within 5 km of the shoreline in this sector and that harbour porpoise in the SS area were more randomly distributed compared to other areas, such as Point Lynas, where they tend to concentrate around specific features (Shucksmith *et al*., 2009).

123. Gordon *et al*. (2011) undertook cetacean surveys off the north-west coast of Anglesey at two locations, Carmel Head and South Stack. The visual and towed hydrophone acoustic surveys, passive acoustic monitoring from static acoustic loggers and visual observations from shore authors were conducted in July and August 2009. Based on acoustic detection rates and assuming a group size of 1.5 (mean of primary and tracker observers mean group sizes), an effective survey strip width of 186m and using no g(0) correction (i.e. they assumed they had seen all of the animals), they estimated that the overall density of harbour porpoise in the two survey areas (Carmel Head and South Stack) to be 0.38 individuals km^2. After applying their expected g(0) of 0.68, the density estimate was 0.56 individuals km^2.

124. Gordon *et al*. (2011) also deployed five automated acoustic data loggers (TPODS) to the north of the Holyhead Deep site around the Skerries and Carmel Head in summer 2009. They confirmed relatively high detection rates of harbour porpoise in the area, with detections every day (and night) of the study. Activity levels were reported to be highest at night, probably due to diurnal patterns in prey availability (Gordon *et al*., 2011).

12.5.1.2.7. Site-Specific Survey Data

125. During the Natural Power boat surveys of the MDZ and 2 km buffer, harbour porpoise was the most frequently sighted cetacean species and comprised 93% of all marine mammals recorded. The total number of observations of harbour porpoise from the 24 months of surveys was 233 individuals (range 0-76 per survey). January 2017 and April 2018 resulted in the highest encounter rates (number of on-effort marine mammal encounters per km survey effort) for harbour porpoise, with 0.255 and 0.177 encounters per km survey effort, respectively (**Appendix 11.1**, **Volume III**).

126. There were sufficient records of harbour porpoise (170) to allow Distance analysis to be undertaken. Within the Site, harbour porpoise peaked at an estimated 1.00 animals/ km^2 during the January 2017 survey (35 individuals). However, it should be noted that although detectability of animals available for detection is accounted for in this analysis, these figures still represent a minimum estimate since the assumption of g(0) = 1 (i.e. all animals were observed and recorded) will provide an underestimate (**Appendix 11.1**, **Volume III**). The harbour porpoise abundance and density estimates for the Natural Power surveys are provided in **Table 12-11**.

127. Over the course of the 24 Natural Power surveys all tidal conditions were encountered within the survey area. The data indicates that the greatest number of porpoises were present mid-tide, when then the tide was rising (**Appendix 11.1**, **Volume III**).

Table 12-11 Harbour porpoise abundance and density estimates (animals/ km^2), lower 95% (confidence limits (LCL) - upper 95% confidence limits (UCL); coefficient of variation (%CV)) derived from distance sampling (Appendix 11.1; Natural Power, 2018).

Survey Month	Abundance (LCL- UCL)	Density (LCL – UCL;%CV)

Survey Month	Abundance (LCL- UCL)	Density (LCL – UCL;%CV)
June 2018	Site = 15 (6 - 37) Buffer = 10 (3 - 29)	Site = 0.42 (0.16 – 1.06; 42.65) Buffer = 0.05 (0.05 – 0.45; 54.32)
July 2018	Site = 6 (1 - 24) Buffer = 10 (3 - 29)	Site = 0.17 (0.04 – 0.67; 66.74) Buffer = 0.05 (0.05 – 0.45; 54.92)
August 2018	Site = 3 (0 - 21) Buffer = 16 (7 - 39)	Site = 0.08 (0.01 – 0.59; 102.55) Buffer = 0.25 (0.10 – 0.59; 41.9)
September 2018	Site = 9 (3 - 25) Buffer = 13 (4 - 42)	Site = 0.25 (0.09 – 0.73; 49.26) Buffer = 0.20 (0.06 – 0.64; 58.6)
October 2018	Site = 12 (5 - 28) Buffer = 6 (2 - 25)	Site = 0.33 (0.14 – 0.81; 40.18) Buffer = 0.10 (0.03 – 0.38; 68.86)

128. Dedicated harbour porpoise surveys have been conducted off West Anglesey as part of the SEACAMS project which includes the Morlais site (**Plate 12-2**). The boat surveys collected visual and acoustic data. Eighteen surveys were completed between January 2015 and December 2016, totalling 25 transects, 884 km of effort on transects covering an area of 707 km^2.

129. The SEACAMS data (**Appendix 12.1**, **Volume III**), provides a range of relative and absolute density estimates calculated for harbour porpoise off Holy Island, Anglesey. The relative density of individuals is estimated to be 0.43 animals per km^2 (CV=0.18). Correcting for incomplete detection on the track line to compensate for under-estimation, density ranges from 0.714 (CV=0.33) to 0.852 (CV=0.33) individuals per km^2, with a mid-point of 0.783 harbour porpoise per km^2 (**Table 12-12**).

130. The SEACAMS density estimate is consistent with the density estimate range from the Natural Power Morlais site surveys of 0.5-1/ km^2 (Natural Power, 2018; **Appendix 11.1**, **Volume III**).

131. The SEACAMS density estimate is higher than the SCANS-III density estimate of 0.239/ km^2 (CV = 0.28) for the Irish Sea area covered by SCANS-III survey block E (Hammond *et al*., 2017). The SEACAMS survey was conducted close to the coast and in high energy waters, both of which are known to be preferred by harbour porpoise (e.g. Shucksmith *et al*., 2005). The increased number of harbour porpoise closer to shore is reflected in the higher density estimates from the shore based surveys conducted by Shucksmith *et al*. (2009) on the North Anglesey Coast and South Stack (**Table 12-12**).

132. For the assessments, the density estimate of 0.783 harbour porpoise per km^2 has been used, based on the SEACAMS data. This was agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

Table 12-12 Harbour porpoise density estimates

Area	Density Estimate	Source
West Anglesey (**Plate 12-2**)	0.714/ km^2 to 0.852/ km^2 (CV=0.33) mid-point = **0.783/ km^2**	SEACAMS (Veneruso *et al*., 2019)
Morlais site surveys* **(Plate 12-1**)	0.5-1/ km^2	Natural Power (2018)

Area	Density Estimate	Source
SCANS-III Block E (**Plate 12-5**)	0.239/ km^2 (CV = 0.28)	Hammond *et al*. (2017)
North Anglesey Coast	1.26/ km^2 (CV = 0.25)	Shucksmith *et al*. (2009)
North Anglesey Coast (South Stack)	2.534/ km^2 (CV = 0.23)	Shucksmith *et al*. (2009)
ObSERVE aerial surveys – stratum 5 Summer 2015 (**Plate 12-6**)	0.696/ km^2 (CV=0.35)	Rogan *et al*. (2018)
ObSERVE aerial surveys – stratum 5 Winter 2015/16 (**Plate 12-6**)	0.867/ km^2 (CV=0.46)	Rogan *et al*. (2018)
ObSERVE aerial surveys – stratum 5 Summer 2016 (**Plate 12-6**)	1.046/ km^2 (CV=0.46)	Rogan *et al*. (2018)
ObSERVE aerial surveys – stratum 5 Winter 2016/17 (**Plate 12-6**)	0.924/ km^2 (CV=0.3)	Rogan *et al*. (2018)
Celtic and Irish Seas (CIS) MU (**Plate 12-4**)	0.858/ km^2 (entire CIS MU) 0.758/ km^2 (UK portion of CIS MU)	IAMMWG (2015)

*Natural Power Morlais site surveys: The precautionary estimate would be 1/ km^2 = the maximum calculated on site, but the mode and median are both 0.17 – which is considerably lower (19 of the 24 samples are below 0.25; 22 of the 24 samples are below 0.5). Therefore, a value of 0.5/ km^2, is a precautionary estimate for 22 of the 24 months.

Table 12-13 Harbour porpoise abundance estimates

Area	Abundance Estimate	Source
Celtic and Irish Seas (CIS) MU (**Plate 12-4**)	**104,695** (95% CI = 56,774-193,065)	IAMMWG (2015)
UK portion of Celtic and Irish Seas (CIS) MU (**Plate 12-4**)	47,229 (95% CI = 25,611-87,094)	IAMMWG (2015)
Celtic/Irish Seas (partial coverage only; **Plate 12-5**)	26,700 (95% CI =16,055-42,128)	Hammond *et al*. (2017)
SCANS-III Block E (**Plate 12-5**)	8,320 (95% CI = 4,643-14,354)	Hammond *et al*. (2017)
North Anglesey Coast	618 (95% CI = 406-909)	Shucksmith *et al*. (2009)
North Anglesey Coast (South Stack)	207 (95% CI = 140-329)	Shucksmith *et al*. (2009)
ObSERVE aerial surveys – stratum 5 Summer 2015 (**Plate 12-6**)	7,734 (95% CI = 5,248 – 11,398)	Rogan *et al*. (2018)

Area	Abundance Estimate	Source

ObSERVE aerial surveys – stratum 5 Summer 2016 (**Plate 12-6**)	11,625 (95% CI = 8,726 – 15,486)	Rogan *et al*. (2018)
ObSERVE aerial surveys – stratum 5 Winter 2016/17 (**Plate 12-6**)	10,264 (95% CI = 7,555 – 13,943)	Rogan *et al*. (2018)
JCP estimate for Celtic and Irish Seas Management Unit	21,714 (95% CI = 20,639.97 23,914.07)	JCP data (Paxton *et al*., 2016)

12.5.1.3. Habitat

133. In coastal waters, aggregations of harbour porpoise are often associated at local sites with strong tidal features, such as headlands, sounds between islands, areas with upwelling, tidal races and rips, often close to reefs and small islands, where prey are probably concentrated into patches providing favourable foraging conditions (Gaskin, 1992; Read and Westgate, 1997; Pierpoint, 2001, 2008; Marubini *et al*., 2009; Shucksmith *et al*., 2009). By-catch data from Ireland suggests that harbour porpoise occur regularly offshore, with records from up to 220 km from land (Rogan and Berrow, 1996) and they have also been sighted in deep water areas beyond the shelf edge (Northridge *et al*., 1995; MacLeod *et al*., 2003).

134. The north coast of Anglesey is characterised by many overlaying rocks and a broken, uneven seabed comprising pinnacles and gullies leading to rapid changes in seabed relief (Gordon *et al.,* 2011). This type of topography, in combination with the area's strong currents, precipitates a range of fine-scale oceanic tidal features with which harbour porpoises are commonly associated (Shucksmith *et al.,* 2009).

135. As outlined in **Chapter 7, Metocean Conditions and Coastal Processes**, most of the sea bed in the MDZ comprises large areas of outcropping bedrock with minimal relief above surrounding bed levels. Secondary bathymetric features include a large, generally symmetric, sand ridge north of South Stack which extends to the northwest for approximately 1 km (within the offshore cable corridor). Within Abraham's Bosom (a bay towards the landfall), the bathymetry is smoother, representing the surface of an area of sediment on top of the bedrock, bounded by rock outcrops to the north and south.

12.5.1.4. Diet

136. The diet of the harbour porpoise consists of a wide variety of fish, including pelagic schooling fish, as well as demersal and benthic species, especially Gadoids, Clupeids and Ammodytes. Other prey species such as cephalopods, other molluscs, crustaceans and polychaetes have also been recorded. The diet varies geographically, seasonally, annually, overtime and differences in diet between sexes or age classes may also exist, reflecting changes in available food resources (Berrow and Rogan, 1995; Kastelein *et al*., 1997; Börjesson *et al*. 2003; Santos and Pierce 2003; Santos *et al*., 2004).

137. The main prey fish species of harbour porpoise typically include sandeels Ammodytidae, whiting *Merlangius merlangus*, herring *Clupea harengus*, sprat *Sprattus sprattus*, cod *Gadus morhua*, haddock *Melanogrammus aeglefinus*, saithe *Pollachius virens*, pollack *Pollachius pollachius*, Norway pout *Trisopterus esmarkii* as well as flat fish such as flounder *Platichthys flesus* and sole *Solea solea* (Rogan and Berrow, 1996; Reid *et al*., 2003; Santos and Pierce, 2003; Santos *et al*., 2004).

138. Taking into account the fish species recorded in the area in **Chapter 10, Fish and Shellfish Ecology**, prey species of harbour porpoise in and around the MDZ is likely to include: sandeel, whiting, cod, mullet species, pollack, herring, sprat, Atlantic mackerel *Scomber scombrus*, horse mackerel *Trachurus Trachurus*, flounder and sole

139. Harbour porpoise tend to concentrate their movements in small focal regions (Johnston *et al*., 2005), which often approximate to particular topographic and oceanographic features and are associated with prey aggregations (Raum-Suryan and Harvey, 1998; Johnston *et al*., 2005; Keiper *et al*., 2005; Tynan *et al*., 2005). Consequently, habitat use is highly correlated with prey density rather than any particular habitat type. However, JNCC (2017a) states that for the Gogledd Môn Forol/North Anglesey Marine SAC, it is unknown which features of the habitat are the most important drivers of the association with prey or what the main prey species of harbour porpoise within the site are.

140. Harbour porpoise have relatively high daily energy demands and need to consume between 4% and 9.5% of their body weight in food per day (Kastelein *et al*., 1997). If a harbour porpoise does not capture enough prey to meet its daily energy requirements it has been estimated that it can rely on stored energy (primarily blubber) for three to five days, depending on body condition (Kastelein *et al*., 1997).

141. A study by Wisnlewska *et al*. (2016) using high-resolution movement and prey echo recording tags on five wild harbour porpoise has shown that porpoises forage nearly continuously day and night, attempting to meet their metabolic demands foraging on small prey.

12.5.1.5. Movements and Seasonal Occurrence

142. The seasonal movements and migratory patterns of harbour porpoise are not well understood. Harbour porpoise may reside within an area for an extended period of time, although onshore / offshore migrations and movements parallel to the shore are also thought to occur (Northridge *et al*., 1995; Bjørge and Tolley, 2002). Seasonal movements are thought to coincide with prey availability and the calving and mating seasons.

143. Harbour porpoise are highly mobile and satellite telemetry work in Danish waters has shown an individual moving more than 1,000 km from Danish waters to east of the Shetland Islands (Teilmann *et al*., 2004). In Danish waters, harbour porpoise have been shown to concentrate their movements in relatively large areas, ranging from approximately 400 to 1,600 km^2 (Teilmann *et al*., 2004). In the western North Atlantic, individuals are known to range over quite large areas, covering as much as 11,289 km^2 within a single month (Johnston *et al*., 2005).

144. Although harbour porpoise are highly mobile and utilise extensive areas over which they range, they tend to occupy small core areas or focal regions for short periods and then make rapid

movements over periods of hours to days across larger scales to other restricted areas (Johnston *et al.,* 2005; Fontaine *et al.,* 2007), which often correspond with reliable feeding opportunities (Marubini *et al*., 2009).

145. In many coastal localities, there can be distinct seasonal peaks in harbour porpoise sightings. The sightings of harbour porpoise in the Irish Sea typically peak during the summer months (in particular June to August) (Evans *et al*., 2015).

146. A study into the temporal and seasonal changes in the distribution of harbour porpoise off the North Cornwall coast revealed the highest peaks in harbour porpoise detections occurred from late December to early March. This trend was shown to be a negative correlation with Sea Surface Temperatures (SST), i.e. as sea temperatures decreased, harbour porpoise detection rates increased. Harbour porpoise detection also varied significantly with the spring-neap tidal cycle, with a significantly increase in detection during neap tides (Cox *et al*., 2017).

147. The seasonal movements and temporal changes in distributional patterns observed are likely to reflect the changes in preferred prey availability and patterns (Skov and Thomsen, 2008; Simon *et al.*, 2010; Sveegaard *et al.*, 2011, 2012).

148. Site-specific surveys indicate that harbour porpoise are present in and around the MDZ year round. As outlined in **Table 12-11**, harbour porpoise were recorded within the site and / or buffer in every month during the Natural Power surveys between November 2016 and October 2018 (**Appendix 11.1**).

12.5.1.6. Life History

149. The calving period for harbour porpoise is primarily between May and July, when sea temperatures are increasing (Read 1990; Sørensen and Kinze 1994; Lockyer, 1995; Bandomir-Krischack 1996; Börjesson and Read 2003; Learmonth *et al*., 2014).

150. At present, not enough is known about harbour porpoise to determine whether some parts of their range are more important for breeding than others. Potential calving grounds have been identified in the German North Sea (Sonntag *et al*., 1999), but there is currently no evidence of specific habitat requirements for mating and calving in UK waters (JNCC, 2002, 2019).

151. Harbour porpoises typically occur in groups of 1-3 animals; larger aggregations have been reported, probably where many smaller groups are concentrated in the same area rather than coordinated schools (Reid *et al*., 2003).

152. During the Natural Power boat surveys of the MDZ and 2 km buffer, most harbour porpoise records were of single animals (73% of sightings) but groups of up to three animals were observed. There were 61 records of two individuals and 11 groups of three individuals recorded. Most of the porpoises recorded were given a behaviour of ‘slow swimming’; with eight records (14 animals) recorded as ‘foraging’, although such behaviour is likely to have been under-recorded (**Appendix 11.1**, **Volume III**).

153. During the SEACAMS surveys, harbour porpoise group size ranged between 1 and 5 animals with a mean estimated group size of 1.53 (CV=0.07; **Appendix 12.1**, **Volume III**).

12.5.1.7. Conservation Status

154. The current conservation status of the harbour porpoise, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2013), is 'Favourable' (JNCC, 2013).

12.5.2. Bottlenose dolphin

12.5.2.1. Distribution and Occurrence

155. The bottlenose dolphin has a worldwide distribution across tropical and temperate seas of both hemispheres and can be found in coastal and continental shelf waters (Reid *et al*., 2003; DECC, 2016). In most regions, including the UKCS, inshore and offshore 'sub-populations' tend to be distinct (DECC, 2016; Oudejans *et al*., 2015; IAMMWG, 2015). In UK waters, inshore individuals are frequently reported off north-east and south-west Scotland, in the Irish Sea, and in the western English Channel (DECC, 2016; IAMMWG, 2015).

156. There are two main areas of UK territorial waters where there are semi-resident groups of bottlenose dolphin: Cardigan Bay in Wales and the Moray Firth on the north-east coast of Scotland. Both of these areas have been designated SAC for bottlenose dolphin. There are also smaller populations of bottlenose dolphin off south Dorset and around Cornwall (Williams *et al.,* 1996; Wither *et al.,* 2012; JNCC, 2019).

157. Bottlenose dolphin are recorded in the western Channel off the coast of Cornwall throughout most of the year (DECC, 2016). A small, possibly resident, population of bottlenose dolphin may also occur in the waters around the Inner Hebrides and sightings are also reported off the west coast of the Outer Hebrides, in the Sound of Barra and in the northern entrance to the Minch (Grellier and Wilson, 2003; Mandleberg, 2006; DECC, 2016; JNCC, 2019). Transient groups are not infrequent almost anywhere around the British coast except the southern North Sea and south-east England (JNCC, 2019).

158. In the Irish Sea, bottlenose dolphin have a predominantly coastal distribution, with higher concentrations off west Wales (particularly Cardigan Bay) and off the coast of Co. Wexford in southeast Ireland. They are also regularly sighted in summer off the Galloway coast of southwest Scotland and around the Isle of Man (Hammond *et al*., 2005, Baines and Evans, 2012; DECC, 2016). During the ObSERVE aerial surveys, only one sighting of five individuals in winter 2016 was made in stratum 5 (**Plate 12-6**), which covered western Irish Sea and east coast of Ireland (Rogan *et al*., 2018).

159. In Welsh waters, the inshore population is centred on Cardigan Bay, although bottlenose dolphin are also regularly observed in the coastal waters between Cardigan Bay and Anglesey (Pesante *et al*., 2008a,b), with concentrations in south Cardigan Bay, south of the Lleyn Peninsula and off Anglesey (Baines and Evans, 2012). There are also regular sightings in the coastal waters to the east of Anglesey around Bull Bay and towards the Llandudno coast (Evans *et al*., 2015). Bottlenose dolphin are most commonly seen in Cardigan Bay within 10 miles of the coast and particularly within two miles; sightings are greatest in the southern portion of the bay (Feingold and Evans, 2014b).

160. During the site-specific boat surveys for the Wylfa Newydd Development Area, two sightings totalling 14 individuals of bottlenose dolphin (a pod of four and 10 individuals respectively). The first sighting occurred in May 2016 to the east of the Wylfa Newydd Development Area, approximately 3 km off Cemaes Bay. The second sighting (consisting of adults and one calf) was recorded in January 2017 to the west of Cemlyn Bay, approximately 4 km offshore (HNP, 2018a). During the Wylfa Newydd Development Area VP surveys between 2011 and 2014, bottlenose dolphin were sighted in Cemlyn Bay and off Cerrig Brith (HNP, 2018a).

161. During the Natural Power surveys between November 2016 and October 2018 (**Appendix 11.1**, **Volume III**), one group of 12 bottlenose dolphin were recorded during the February 2018 survey.

162. Three sightings of bottlenose dolphin were recorded during the SEACAMS surveys (**Appendix 12.1**, **Volume III**).

12.5.2.2. Abundance and Density Estimates

12.5.2.2.1. Irish Sea Management Unit

163. A number of inshore groups of bottlenose dolphin have been identified in UK and Irish waters and there appears to be limited interchange between these groups Robinson *et al*., 2012; Cheney *et al*., 2013; ICES, 2014; IAMMWG, 2015).

164. IAMMWG (2015) currently recognise seven MUs for bottlenose dolphin in UK waters:

(1) Coastal West Scotland and the Hebrides (CWSH, to 12nm);

(2) Coastal East Scotland (CES, to 12nm);

(3) Greater North Sea (GNS);

(4) Offshore Channel and SW England (OCSW);

(5) Coastal West Channel (CWC, to 12nm);

(6) Irish Sea (IS); and

(7) Oceanic Waters (OW).

165. The MDZ is located in the Irish Sea MU (**Plate 12-8**), which has an estimated bottlenose dolphin abundance of 397 (CV = 0.23; 95% CI = 362-414; IAMMWG, 2015; **Table 12-15**). This reference population was agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

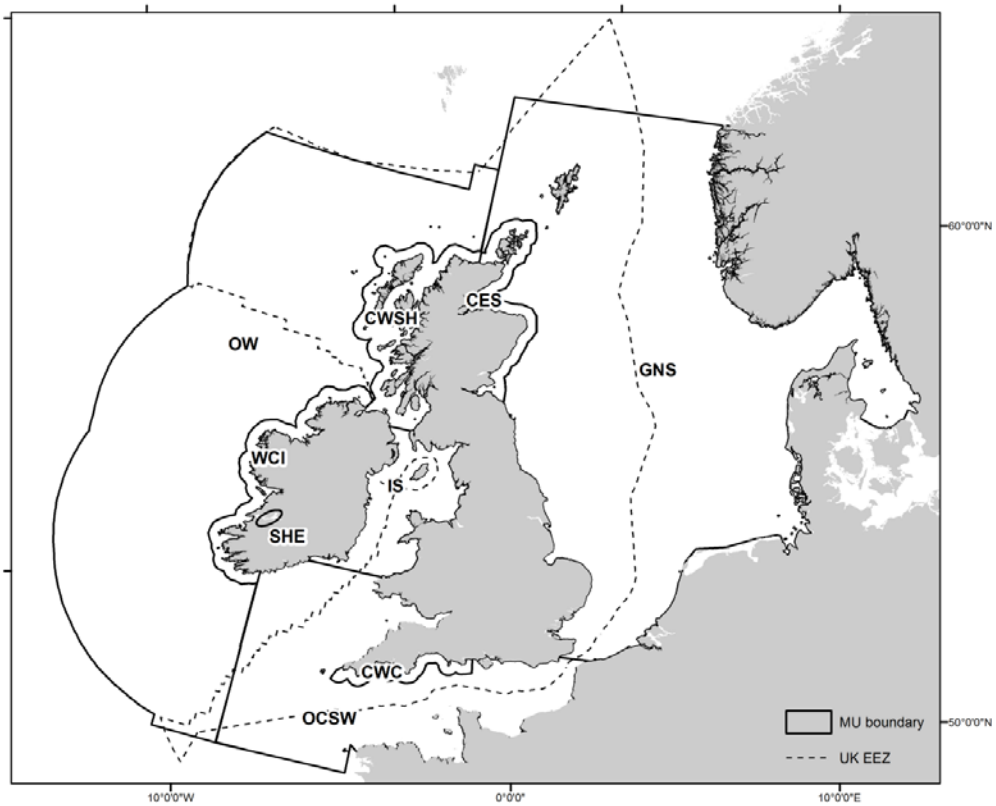

Plate 12-8 Bottlenose Dolphin MUs (source: IAMMWG, 2015)

12.5.2.2.2. SCANS data

166. For the entire SCANS-II survey area, bottlenose dolphin abundance in the summer of 2005 was estimated to be 16,485 (CV = 0.422; Hammond *et al*., 2013). The SCANS-II survey estimated the abundance of bottlenose dolphin in survey block O, which is located in the Irish Sea and includes the MDZ, to be 235 individuals (CV=0.75) and the density was estimated to be 0.0052 bottlenose dolphin per km^2 (CV=0.75) (Hammond *et al*., 2013).

167. For the entire SCANS-III survey area (not the same as SCANS-II area), bottlenose dolphin abundance in the summer of 2016 was estimated to be 27,697 with an overall estimated density of 0.015/ km^2 (CV = 0.233; 95% CI = 17,662 – 43,432; Hammond *et al*., 2017).

168. The SCANS-III survey estimated that the abundance of bottlenose dolphin in survey block E (**Plate 12-5**; surface area of 34,870 km^2), which is located in the Irish Sea and includes the MDZ, was 288 individuals and the density was estimated to be 0.008 bottlenose dolphin per km^2, with a mean group size of 1.50 (CV = 0.57; 95% CI = 0-664; Hammond *et al*., 2017). In the adjacent area, survey block F (**Plate 12-5**; surface area of 12,322 km^2), no bottlenose dolphin were recorded (Hammond *et al*., 2017).

12.5.2.2.3. Cardigan Bay

169. Cardigan Bay is the largest population in the UK with annual estimates for the wider area varying between 254 and 330 animals (CV = 0.25 – 0.28) for the years 2011 and 2013 inclusive (Feingold and Evans, 2013, 2014a, b).

170. Maximum density estimate based on area of Cardigan Bay Special Area of Conservation (SAC) (approx. 959 km^2) and maximum number of dolphins in the population (330 individuals), is 0.344 bottlenose dolphin per km^2.

171. The population is not closed as individuals may join up for periods of time from elsewhere (Reid *et al*., 2003) and sightings of individuals initially reported off the south-west coast of England, have been observed in Welsh waters (Wood, 1998; Hammond *et al*., 2008).

172. Photo identification studies completed by the Sea Watch Foundation (Veneruso and Evans, 2012a,b) have revealed that of 221 bottlenose dolphin recorded between 2007 and 2012 off the north coast of Anglesey, 141 (64%) had been previously recorded within the Bae Ceredigion/ Cardigan Bay SAC, as well as north of the Llyn Peninsula, and many had additionally been recorded within the Pen Llyn a'r Sarnau/Llyn Peninsula and the Sarnau SAC (Veneruso and Evans, 2012a,b). This indicates that the majority of the Cardigan Bay population of bottlenose dolphin move between the two sites.

173. Within the same study, bottlenose dolphin encountered from the north coast of Anglesey (n=28) were investigated to determine the seasonal movements of bottlenose dolphin. It was revealed that of the dolphins recorded in the winter surveys (December to February), 95% had previously been recorded within Cardigan Bay, supporting the theory that there is a seasonal movement of dolphins from Cardigan Bay to the north coast of Anglesey within the winter months (Veneruso and Evans, 2012a,b). During spring (March to May), 62% of the individuals recorded along the north coast of Anglesey had previously been recorded in Cardigan Bay, 38% were recorded in the summer (June to August) and 98% in the autumn (September to November). This pattern gives a clear indication of the movement of bottlenose dolphins from Cardigan Bay in summer to the north coast of Anglesey and the Llyn Peninsula in the autumn and winter (Veneruso and Evans, 2012a,b).

174. A review of the field research (2011-13) conducted by the Sea Watch Foundation for bottlenose dolphin in the Cardigan Bay and Pen Llŷn a’r Sarnau SACs (Feingold and Evans, 2014b), indicates that the entire coastal area from Aberaeron to Cardigan appears to be of particular significance. Bottlenose dolphin sightings have also been regularly reported in North Wales, particularly around the Isle of Anglesey but extending east into Liverpool Bay and north to at least the Isle of Man (Feingold and Evans, 2014b).

175. Photo-identification surveys off the coast of Anglesey, along with data provided from the Isle of Man and Liverpool Bay, indicate that individuals from Cardigan Bay extend their home ranges, particularly in winter, to the northern Irish Sea at least as far as the Isle of Man (Feingold and Evans, 2014b).

176. In addition to winter sightings of the species in the northern Irish Sea, bottlenose dolphin have also been recorded off the North Wales coast and across to Liverpool Bay in summer (Feingold and Evans, 2014b; Veneruso and Evans, 2011a,b).

12.5.2.2.4. Site-Specific Survey Data

177. There is currently insufficient data from the site-specific surveys to provide any estimates for abundance or density (**Appendix 11.1** and **12.1**, **Volume III**).

178. To take into account the range of bottlenose dolphin from Anglesey to Cardigan Bay, including the Cardigan Bay SAC and Lleyn Peninsula SAC (**Figure 12-1, Volume II**), the density estimate has been based on 330 dolphins in an area of 16,098 km^2 (**Table 12-14**). For the assessments, the density estimate of 0.02 bottlenose dolphin per km^2 has been used. This was agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

Table 12-14 Bottlenose dolphin density estimates

Area	Density	Source	Notes
Area from Anglesey to Cardigan Bay (**Figure 12-1, Volume II**)	**0.02/ km^2**	Feingold and Evans (2013)	Density estimate is based on area of 16,098 km^2 and maximum number of 330 individuals.
Cardigan Bay SAC and Lleyn Peninsula SAC	0.136/ km^2	Feingold and Evans (2013)	Density estimate is based on area of Cardigan Bay SAC & Lleyn Peninsula and the Sarnau SAC (approx. 2,419 km^2) and maximum number of 330 individuals.
Cardigan Bay SAC	0.344/ km^2	Feingold and Evans (2013)	Density estimate is based on area of Cardigan Bay SAC (approx. 959 km^2) and maximum number of 330 individuals.
Lleyn Peninsula SAC	0.226/ km^2	Feingold and Evans (2013)	Density estimate based on area of Lleyn Peninsula and the Sarnau SAC (approx. 1460 km^2) and maximum number of BND (330 individuals).
SCANS-III Block E (**Plate 12-5**)	0.008/ km^2 (CV = 0.57)	Hammond *et al*. (2017)	For context of the density estimate for the wider area.

JCP estimate for Irish Seas Management Unit	1,863 (95% CI = 1,827 – 1,890)	JCP data (Paxton *et al*.,2016)

12.5.2.3. Habitat

179. Throughout its range, the bottlenose dolphin occurs in a diverse range of habitats, from shallow estuaries and bays, coastal waters, continental shelf edge and deep open offshore ocean waters. However, it is primarily an inshore species, with most sightings within 10 km of land, but they can also occur offshore, often in association with other cetaceans (JNCC, 2019).

180. In coastal waters, bottlenose dolphin are often associated with river estuaries, headlands or sandbanks, where there is uneven bottom relief and/or strong tidal currents (e.g. Lewis and Evans, 1993; Wilson *et al*., 1997; Liret *et al*., 1998; Liret, 2001; Ingram and Rogan 2002; Reid *et al*., 2003).

181. Within Cardigan Bay, bottlenose dolphins appear to use specific habitats consistently. Areas within 3.2 km of the shoreline, with strong currents, in proximity to rocky headlands and near small embayments and estuaries, are the habitats most frequented by the bottlenose dolphin (Lewis and Evans, 1993; Arnold and Mayer, 1995).

182. Within Cardigan Bay, bottlenose dolphin appear to use specific habitats. For example, areas within 3.2 km of the shoreline, with strong currents, in proximity to rocky headlands and near small embayments and estuaries, are the habitats most frequented by the bottlenose dolphin (Lewis and Evans, 1993; Arnold and Mayer, 1995). Habitat analysis shows preference for areas between 5m and 10m in depth, although areas of between 25m and 30m depth have seen an increase in sightings since 2005 with the majority of the sightings in this region occurring over the slope range of Cardigan Bay (Pesante *et al.,* 2008b).

183. The predominant bottlenose dolphin behaviour noted within the Cardigan Bay SAC was travelling or foraging, while in Pen Llyn the behaviours noted included consistently higher levels of socialising behaviours (Norrman *et al*., 2015). This suggests that the northern sector of Cardigan Bay may be a socialising and mating ground whereas the southern areas are key foraging and nursery areas (Norrman *et al*., 2015).

184. A photo-monitoring study researching connectivity of bottlenose dolphin in Wales (Pesante *et al*., 2008a), suggests that their preference for Cardigan Bay is a result of the shallow bathymetry and diverse benthic habitats, in addition to the fact that significant numbers of salmonids pass through the bay during migration.

12.5.2.4. Diet

185. Bottlenose dolphin are opportunistic feeders and take a wide variety of fish and invertebrate species. Benthic and pelagic fish (both solitary and schooling species), including haddock, saithe, pollock, cod, whiting, hake *Merluccius merluccius*, blue whiting *Micromesistius poutassou*, bass *Dicentrarchus labrax*, mullet Mugilidae, mackerel Scombridae, salmon *Salmo salar*, sea trout *Salmo trutta trutta*, flounder, sprat and sandeels, as well as octopus and other cephalopods have all been recorded in the diet of bottlenose dolphin (Santos *et al*., 2001; Santos *et al*., 2004; Reid *et al*., 2003).

186. In Irish waters, haddock, saithe and pollock are the dominant prey species, followed by whiting, blue whiting, Atlantic mackerel and horse mackerel; cephalopods are also important (Hernandez-Milian *et al*., 2015). The stomach contents analysis of three individuals in the Irish

Sea indicated a highly variable diet comprising horse mackerel, hake, mackerel, poor cod, pollock, whiting and saithe (Couperus, 1995; O'Brien and Berrow, 2006).

187. Diet analysis suggests that bottlenose dolphin are selective opportunists and although they may have preference for a type of prey, their diet seems to be determined largely by prey availability. Research in Australia has shown that when presented with a choice, they will preferentially feed on certain types of prey, particularly those with a high fat content (Corkeron *et al*., 1990).

188. Taking into account the fish species recorded in the area, as outlined in **Chapter 10, Fish and Shellfish Ecology**, the main prey species of bottlenose dolphin in and around the MDZ is likely to include a wide range of prey species such as salmon, sea trout, bass, mullet, whiting, mackerel, sandeels and flat fish.

12.5.2.5. Movements and Seasonal Occurrence

189. Greatest numbers are thought to occur in UK waters between July and October with a secondary peak in some localities in March-April (Reid *et al.,* 2003; Evans *et al.,* 2003) although animals are present all year round in some areas (Wilson *et al.,* 1997; Veneruso and Evans, 2012a, b; Cheney *et al.,* 2013). Analyses of photo-identification data from multiple studies have also shown that bottlenose dolphin can make long-distance movements (Robinson *et al.,* 2012).

190. In Cardigan Bay, the population ranges over an area wider than the SAC, which likely includes all of the west and north Wales coasts and a wide area of the Irish Sea (DECC, 2016). The distribution of bottlenose dolphin is variable with main concentrations in the summer being around Tremadog Bay and southern Cardigan Bay (Evans *et al.,* 2015; Feingold and Evans, 2014b). Sightings of bottlenose dolphin occurring around the coast of north Wales, primarily Anglesey, differed considerably to those in Cardigan Bay, with the most frequent sightings occurring during winter (Pesante *et al.,* 2008b), suggesting possible seasonal movements in the area (Norman *et al.,* 2015). Although there are a higher number of bottlenose dolphin off north Anglesey in the winter months, bottlenose dolphin are present off north Anglesey throughout the year (Veneruso and Evans, 2012a, b).

191. During photo-identification studies of bottlenose dolphin in Scotland, one individual was identified south of Aberdeen and then re-identified off Burghead 52 hours later, representing a distance of 218 km and a minimum swimming speed of 4.2 km/h (Wilson *et al.,* 2004). For consecutive sightings five or less days apart, the median rate of travel for dolphins identified primarily within the inner Moray was 0.071 km/h, whereas for dolphins observed using areas outwith the inner Moray Firth it was significantly greater at 0.22 km/h. Similarly, during sightings in the outer Moray Firth and along the coasts south of Fraserburgh the median rate of progress was 7.6 km/h, which was twice as fast as in the inner Moray Firth (3.9 km/h) (Wilson *et al.,* 2004).

12.5.2.6. Life History

192. Indications suggest that bottlenose dolphin in UK waters may have two calving peaks in the year (Evans, 1980) or an extended breeding season, meaning that calves can often be observed throughout the year. Calves stay with their mothers for at least four years (Smolker *et al*., 1992), but have been reported to stay together until the calf is eight years old (Grellier *et al*., 2003).

193. Cardigan Bay SAC is an important calving area for bottlenose dolphin. There are also two other important calving areas in north wales: the Pen Llyn Sarnau and the Isle of Anglesey (Feingold and Evans, 2013, 2014a). Peak calving times within the Cardigan Bay SAC are generally between July and September (when approximately 76% of all calves are born), although calving may occur at any time (Norrman *et al*., 2015).

194. There is currently not enough information to determine what, if any, the habitat requirements are for any breeding areas or calving areas for bottlenose dolphins in UK waters.

12.5.2.7. Conservation Status

195. The current conservation status, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), of the bottlenose dolphin is 'favourable' (JNCC, 2013).

12.5.3. Risso's dolphin

12.5.3.1. Distribution and Occurrence

196. Risso's dolphin are seasonally recorded in the Celtic and Irish Seas (IAMMWG, 2015). There distribution is thought to be a relatively localised, running in a wide band running southwest to northwest Wales, encompassing west Pembrokeshire, the western end of the Lleyn Peninsula and Anglesey (Evans *et al.,* 2015). Risso's dolphin are also found on the southeast coast of Ireland and around the Isle of Man (Baines and Evans, 2012).

197. During the ObSERVE aerial surveys, sightings of Risso's dolphins were recorded in summer 2015 and 2016 in stratum 5 (**Plate 12-6**), which covered western Irish Sea and east coast of Ireland. These coastal sightings in the western Irish Sea likely represent a frequently sighted community that regularly appears near the Saltee Islands off Co. Wexford (Rogan *et al*., 2018).

198. Risso's dolphin are sighted regularly around the northern and western part of the Lleyn Peninsula, with a hot spot around Bardsey Island, and are rarely sighted in Cardigan Bay (Baines and Evans, 2012). Risso's dolphin are thought to present along the north coast of Anglesey all year round. Although abundance increases during the summer and autumn months (July to October) however sightings vary every year (Baines and Evans, 2012).

199. There were no sightings of Risso's dolphin along the north coast of Anglesey during land-based surveys undertaken for the Wylfa Newydd project during 2011 to 2014 (HNP, 2018) and only one sighting of a single individual was recorded during transit for the dedicated vessel transect surveys. The dedicated vessel transect surveys yielded three sightings of Risso's dolphin with an average pod size of two individuals (HNP, 2018a).

200. During the Natural Power surveys between November 2016 and October 2018, Risso's dolphin were encountered during three surveys (September 2017, May and October 2018; **Appendix 11.1**, **Volume III**). The two sightings of 8 individuals during the September 2017 survey was outwith the MDZ and buffer area. During the May 2018 survey there were two observations of 11 individuals and during the October 2018 survey there were three observations of 20 individuals. Most of these observations were in the buffer area rather than the MDZ (**Plate 12-9**).

201. Four sightings of Risso's dolphin were recorded during the SEACAMS surveys and these were all outside of the MDZ (**Appendix 12.1**, **Volume III**).

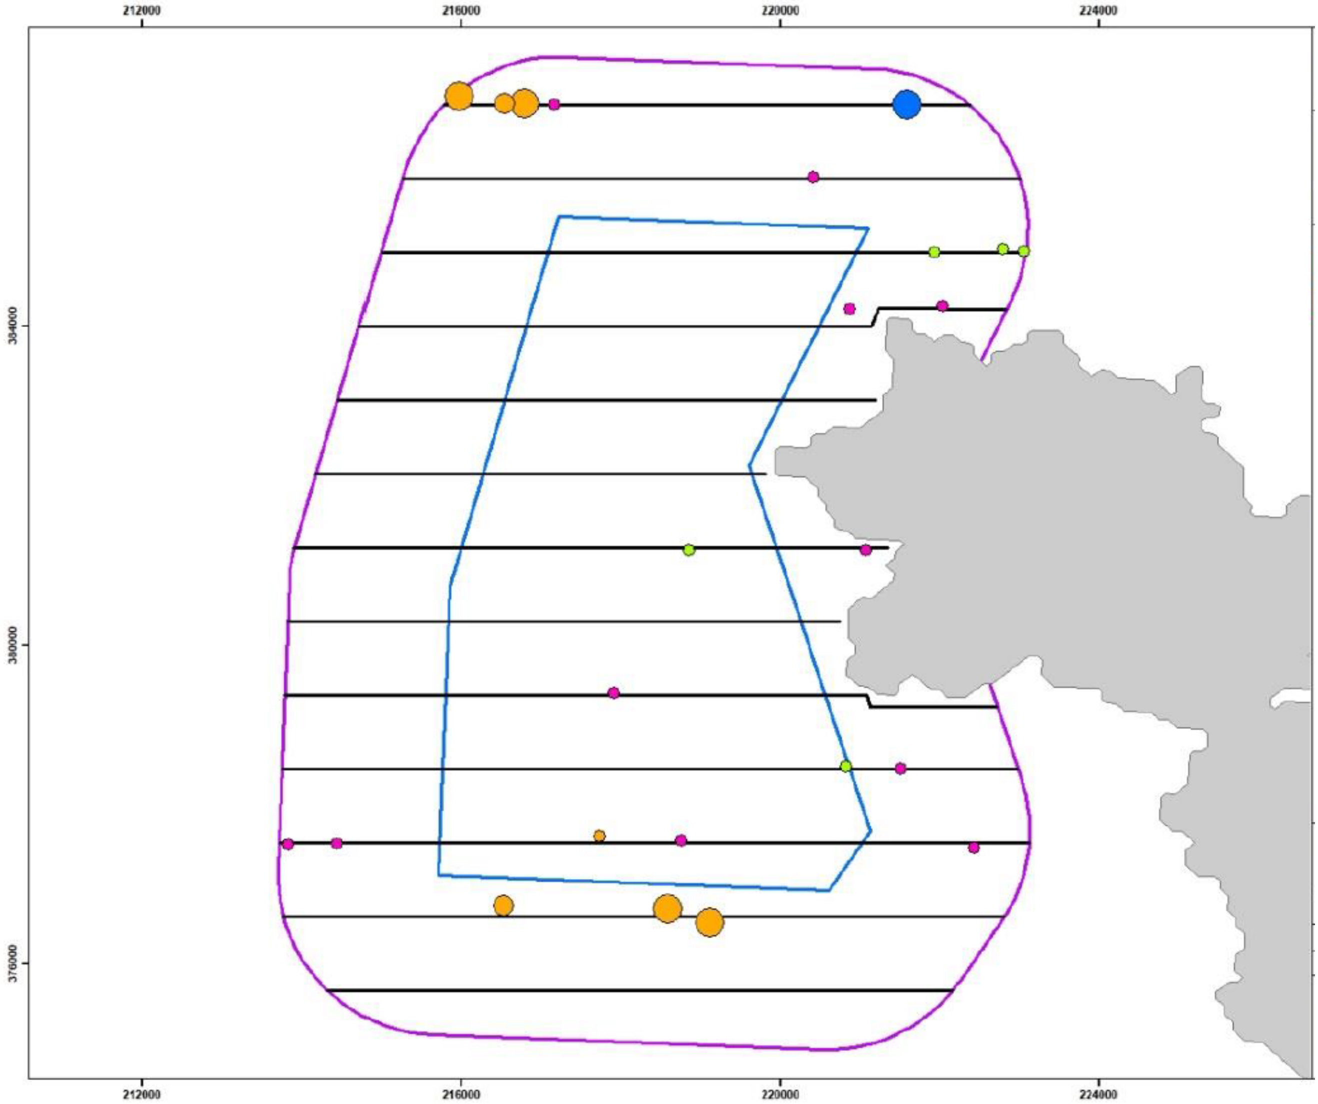

Plate 12-9 Distribution of marine mammal (excluding harbour porpoise) sightings (on-effort, off-effort and incidental) survey during Natural Power surveys (November 2016 to October 2018; Appendix 11.1)

12.5.3.2. Abundance and Density Estimates

202. The IAMMWG (2015), recommends a single MU, the Celtic and Greater North Seas (CGNS) MU comprising all UK waters and extending to the seaward boundary used by the European Commission for Habitats Directive reporting, with the eastern boundary determined by OSPAR's Regional Seas boundary (**Plate 12-10**).

203. The JCP abundance estimate for Risso's dolphin in the Celtic and Greater North Sea Management Unit is 8,794 (95% CI = 8,695 – 8,848) (Paxton *et al.,* 2016; **Table 12-16**). The JCP abundance estimates of Risso's dolphin in the Irish Sea Development Area were highest in spring with an abundance estimate of 70 individuals (CI = 0 – 280) and summer abundance estimate of 30 individuals (CI = 0 – 160) (Paxton *et al*., 2015).

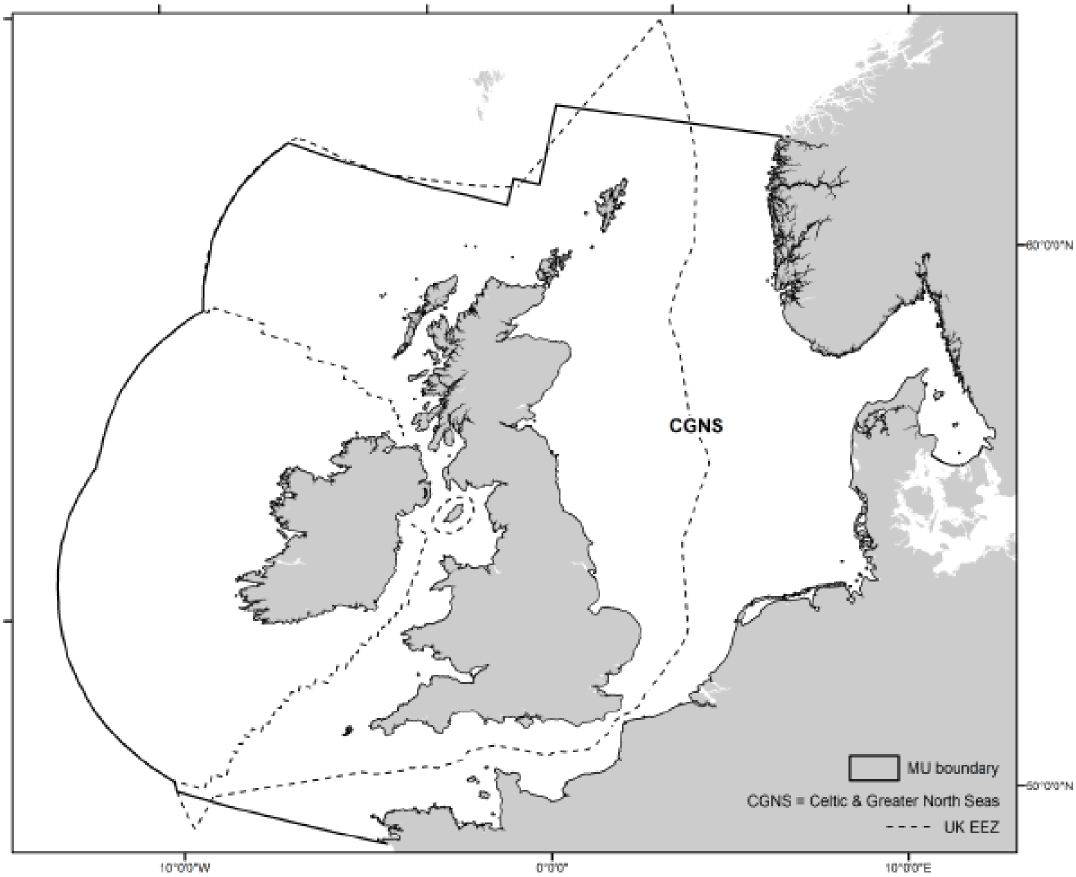

Plate 12-10 Celtic and Greater North Seas (CGNS) MU (source: IAMMWG, 2015)

204. The SCANS-III survey estimated that the abundance of Risso's dolphin in survey block E, which is located in the Irish Sea and includes the MDZ (**Plate 12-5**), was 1,090 individuals and the density was estimated to be 0.031 Risso's dolphin per km^2, with a mean group size of 7.50 (CV = 0.69; 95% CI = 0-2,843; Hammond *et al*., 2017; **Table 12-16**). In the adjacent area, survey block F, no Risso's dolphin were recorded (Hammond *et al*., 2017).

Table 12-16 Risso's dolphin abundance and density estimates

Area	Abundance Estimate	Density Estimate	Source
SCANS-III Block E (**Plate 12-5**)	1,090 (95% CI = 0-2,843)	**0.031/ km^2** (CV = 0.69)	Hammond *et al.* (2017)
JCP estimate for Celtic and Greater North Sea Management Unit (**Plate 12-10**)	**8,794** (95% CI = 8,695 – 8,848)	N/A	JCP data
ObSERVE aerial surveys – stratum 5 (Summer 2015) (**Plate 12-6**)	35.1 (95% CI =7-188)	0.0032/ km^2 (CV=0.96)	Rogan *et al.* (2018)

12.5.3.3. Diet

205. Risso's dolphin feed mostly on cephalopods including octopus, cuttlefish, and small squid (Santos *et al*. 1994). They also feed on pelagic and benthic fish species (Kruse *et al*. 1999; Bloch *et al*. 2012).

12.5.3.4. Conservation Status

206. The current conservation status, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), of the Risso's dolphin is 'unknown' (JNCC, 2013).

12.5.4. Common dolphin

12.5.4.1. Distribution and Occurrence

207. The common dolphin is the most numerous offshore cetacean species in the north east Atlantic, most often sighted off the western coast of the UK, in the Celtic Sea, and western approaches to the Channel (Reid *et al*., 2003).

208. The MU for common dolphin encompasses the whole of the Celtic and Greater North Seas (**Plate 12-10**), with the majority of sightings having been reported south of 60˚N (Murphy *et al*. 2013; IAMMWG, 2015). The distribution of common dolphins in the Irish Sea is typically concentrated in the south, in an area offshore of Pembrokeshire called Celtic Deep, just within the 12nm territorial limit of Wales (Baines and Evans, 2012). In the northern Irish Sea, the densities of common dolphin are relatively low with another hotspot for common dolphin off the Isle of Man (Baines and Evans, 2012).

209. No common dolphin were recorded in stratum 5 of the Irish Sea (**Plate 12-6**) during the ObSERVE aerial surveys in summer and winter 2015 and 2016 (Rogan *et al*., 2018).

210. Sightings in Welsh waters are mainly in the summer with fewer individuals recorded in the winter, however it should be noted that survey effort in the winter months is low (Baines and Evans, 2012). However, the Phase-III Joint Cetacean Protocol reported the highest abundance estimate of 310 common dolphin (CI = 110 – 860) in autumn, which is significantly higher than summer estimate of 80 common dolphin (CI = 30 – 260) (Paxton *et al*., 2017).

211. One sighting was recorded for common dolphin by the Sea Watch Foundation (2019) which was for a group of 10 at Point Lynas, Anglesey on the 17th November 2018 (Sea Watch Foundation, 2019).

212. No common dolphin were sighted during the site-specific surveys for the Wylfa Newydd Development Area (HNP, 2018a).

213. No common dolphin were sighted during the MDZ site specific surveys conducted by Natural Power (**Appendix 11.1, Volume III**) and SEACAMS (**Appendix 12.1, Volume III**).

12.5.4.2. Abundance and Density Estimates

214. The abundance of common dolphin in the CGNS MU is 56,556 (CV = 0.28; 95% CI = 33,014-96,920; **Table 12-17**) and the UK component (abundance within the UK EEZ) is 13,607 (CV = 0.23; 95% CI = 8,720-21,234). These estimates were derived from SCANS-II (Hammond *et al*., 2013) and Cetacean Offshore Distribution and Abundance in the European Atlantic (CODA; Macleod *et al*., 2009) and are likely to be biased low due to perception bias that could not be corrected for in the aerial surveys (IAMMWG, 2015).

215. The SCANS-III survey did not record any common dolphin in survey block E (surface area of 34,870 km^2). SCANS-III survey block D, which is also located in the south-west (**Plate 12-5**) had an abundance of 18, 458 and the density was estimated to be 0.374/ km^2, with a mean group size of 10.06 (CV = 0.41, 95% CL = 4,394 – 33,077; Hammond *et al*., 2017).

216. A density estimate has been derived based on the density estimate of SCANS-III survey block D, which assumes the animals in block D could also be distributed in block E. A density of 0.22 common dolphin per km^2 was estimated based on 18,458 common dolphin in the total area (83,460 km^2) of survey blocks D and E (**Plate 12-5 Table 12-17**). This approach was agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

Table 12-17 Common dolphin abundance and density estimates

Area	Abundance Estimate	Density Estimate	Source
Celtic and Greater North Sea (CGNS) MU (**Plate 12-10**)	**56,556** (95% CI = 3,989-39,572) for CGNS MU 13,607 (95% CI=7,176-21,066) for UK portion of CGNS	N/A	IAMMWG (2015)
SCANS-III Block E (**Plate 12-5**)	0	0	Hammond *et al*. (2017)
SCANS-III Block D (**Plate 12-5**)	18, 458 (CV = 0.41, 95% CL = 4,394 – 33,077)	0.374/ km^2 (CV = 0.41, 95% CL = 4,394 – 33,077)	Hammond *et al*. (2017)
SCANS-III Block E and D (**Plate 12-5**)	18, 458	**0.22/ km^2**	Estimate based on 18,458 common dolphin in the total area (83,460 km^2) of survey blocks D and E

12.5.4.3. Diet

217. Common dolphins have a varied diet and are opportunistic feeders that often use cooperative feeding techniques to herd schools of fish (Sea Watch Foundation, 2012). Their diet depends on local prey availability and may include small schooling fish including hake, cod, sardine, mackerel, horse mackerel, scad, sprat, herring, sandeel, whiting, blue whiting, and squid (Sea Watch Foundation, 2012).

12.5.4.4. Conservation Status

218. The current conservation status of common dolphin, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), is 'favourable' (JNCC, 2013).

12.5.5. Minke whale

12.5.5.1. Distribution and Occurrence

219. Minke whale are widely distributed along the Atlantic seaboard of Britain and Ireland (Reid *et al*., 2003). Within UK waters, minke whale are most commonly sighted in the western central North Sea and the west of Scotland around the Hebrides (DECC, 2016).

220. Minke whale are predominantly a seasonal visitor to UK waters, with sightings increasing from May to October, with sightings rare outside of this period. However, there are some individuals that are known to be resident in UK waters year-round (Evans, 2008). The annual movement patterns and migrations of minke whale are not well understood, but it is thought that they make a migration between tropical breeding grounds in the winter to colder feeding grounds in the summer (HWDT, 2019).

12.5.5.2. Abundance and Density Estimates

12.5.5.2.1. Celtic and Greater North Seas Management Unit

221. Genetic evidence suggests that the minke whales of the North Atlantic are likely to be a single genetic population (Anderwald *et al*., 2012). Therefore, IAMMWG (2015) considers a single MU is appropriate for minke whales in European waters.

222. The abundance of minke whales in the CGNS MU (**Plate 12-10**) is 23,528 animals (CV = 0.27; 95% CI = 13,989-39,572; IAMMWG 2015; **Table 12-18**). The estimate was derived from SCANS-II (Hammond *et al*., 2013) and CODA (Macleod *et al*., 2009) and is likely to be underestimated. The IAMMWG (2015) note the abundance of minke whales is highly seasonal, with abundance peaking during migration south into waters around the UK for summer.

12.5.5.2.2. JCP Data

223. The JCP estimated densities of minke whale across UK waters in summer are 0.02-0.04 individuals per km^2 (97.5% CI = 0-0.02 – 0.1-0.2 per km^2; Paxton *et al*., 2016).

224. The JCP abundance estimates for the Irish Sea Development area are highest in summer, with an estimated abundance of 190 individuals (97.5% CI = 80 – 620) and for winter months the estimated abundance is 60 individuals (97.5% CI = 0-100; Paxton *et al*., 2016).

12.5.5.2.3. SCANS and ObSERVE Data

225. SCANS-I in July 1994 estimated 8,445 minke whale (95% CI = 5,000-13,500) (Hammond *et al*., 2002). The SCANS-II survey gave an overall estimate of 18,958 minke whale (CV = 0.347); and 13,734 minke whale (CV = 0.41; 95%CI = 9,800 – 36,700) within an area comparable to the 1994 survey (Hammond *et a*l., 2013). Although these estimates were not significantly different, there were noticeable changes in distribution between the two surveys which is most likely to be linked to changes in prey availability.

226. For the entire SCANS-III survey area (not the same area as SCANS-II), minke whale in the summer of 2016 was estimated to be 14,759 with an overall estimated density of 0.008/ km^2 (CV = 0.327; 95% CI = 7,908-27,544; Hammond *et al*., 2017).

227. For the SCANS-III survey block E (**Plate 12-5**), the abundance of minke whale in the summer of 2016 was estimated as 603 individuals (CV = 0.62, 95% CI 134 – 1,573) with an estimated density of 0.017 individuals per km^2 (Hammond *et al*., 2017; **Table 12-18**).

228. ObSERVE aerial surveys estimated minke whale density in stratum 5 to be 0.045/ km^2 in Summer 2015 and 0.016/ km^2 in summer 2016 (Rogan *et al*., 2018).

Table 12-18 Minke whale abundance and density estimates

Area	Abundance Estimate	Density Estimate	Source
Celtic and Greater North Seas (CGNS) MU (**Plate 12-10**)	**23,528** (95% CI = 3,989-39,572) for CGNS MU 12,295 (95% CI=7,176-21,066) for UK portion of CGNS	N/A	IAMMWG (2015)
SCANS-III Block E (**Plate 12-5**)	603 (95% CI = 134-1,753)	**0.017/ km²** (CV = 0.62)	Hammond *et al*. (2017)
ObSERVE aerial surveys – stratum 5 Summer 2015 (**Plate 12-6**)	494.7 (95% CI = 221.5 – 1105)	0.045/ km² (CV=0.69)	Rogan *et al*. (2018)
ObSERVE aerial surveys – stratum 5 – Summer 2016 (**Plate 12-6**)	180.1 (95% CI = 58.6 – 552.9)	0.016/ km² (CV=1.06)	Rogan *et al*. (2018)

12.5.5.3. Diet

229. Minke whales feed on a variety of fish species, including herring, cod and haddock. Minke whale feed by engulfing large volumes of prey and water, which they then 'sieve' out of through their baleen plates and swallow their prey whole.

230. A study into the diet of minke whale in the north-eastern Atlantic sampled a total of 210 minke whale forestomach contents from 2000 to 2004, with a total of 37 minke whale samples analysed within the northern North Sea. Within this area, minke whale were found to prey upon a number of different species at the population level, however, 84% of individuals were found to prey upon only one species. Sandeels (56% of total prey by biomass) and mackerel (30% of total prey by biomass) were found to be the most dominant prey species for minke whale in the northern North Sea (Windsland *et al*., 2007).

12.5.5.4. Conservation Status

231. The current conservation status of minke whale, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), is 'favourable' (JNCC, 2013).

12.5.6. Grey seal

12.5.6.1. Distribution and Occurrence

232. Grey seals only occur in the North Atlantic, Barents and Baltic Sea with their main concentrations on the east coast of Canada and United States of America and in north-west Europe (SCOS, 2017).

233. Approximately 38% of the world's grey seals breed in the UK and 88% of these animals breed at colonies in Scotland with the main concentrations in the Outer Hebrides and in Orkney. There are also breeding colonies in Shetland, on the north and east coasts of mainland Britain and in south-west England and Wales (SCOS, 2017). Although the number of grey seal pups born in the UK has been growing steadily since records began in 1960, the population growth is now

steadying in all areas except for the central and southern North Sea where population growth remains high (SCOS, 2017).

234. Long-term sightings rates data as collated in the Atlas of the Marine Mammals of Wales found that the main concentrations of grey seals sightings were off the north coast of Wales, as well as the southern coast of the Isle of Man (Baines and Evans, 2012).

235. Marine Scotland commissioned Sea Mammal Research Unit (SMRU) to produce maps of grey seal distribution in UK waters (Russell *et al*., 2017). These maps were produced by combining information about the movement patterns of electronically tagged seals with survey counts of seals at haul-out sites. The resulting maps show estimates of mean seal usage (seals per 5 km x 5 km grid cell). The maps indicate relatively higher usage in some areas of the Celtic and Irish Sea along coastal locations of Ireland and Wales, for example, Llŷn Peninsula and West Hoyle Bank in Wales and the waters surrounding Lambay Island, as well as the south-east tip (Saltee Islands) of Ireland. Although, mean grey seal usage is relatively low (1<5 animals) in the area in and around the MDZ (Russell *et al*., 2017).

236. Grey seal are regularly recorded in and around the Irish Sea, including north Anglesey (e.g. Westcott, 2002; Westcott and Stringell, 2003, 2004; Clarke *et al*., 2018). Grey seals are present year round on both the Irish and Welsh coasts and are known to move between the two, for example between the southeast coast of Ireland and the southwest coast of Wales (Kiely *et al*., 2000).

237. During the Natural Power surveys of the MDZ and 2 km buffer (**Appendix 11.1, Volume III**), grey seal were recorded throughout the survey period between November 2016 and October 2018. Records of unidentified seals were also made, but as no harbour seals were recorded, it is considered likely that these records were also of grey seals. Ten sightings of grey seal were recorded during the SEACAMS surveys (**Appendix 12.1, Volume III**).

12.5.6.2. Abundance and Density Estimates

238. Grey seal populations are assessed from the counts of pups born each year. Surveys are undertaken during the breeding season where females will congregate on land to give birth (SCOS, 2017). The most recent counts available are from the 2014 autumn breeding season surveys, that were released in 2016. The 2014 surveys of the principal grey seal breeding sites in Scotland, Wales, Northern Ireland and south-west England, resulted in an estimate of 60,500 pups (95% CI = 53,900 - 66,900; SCOS, 2017). The pup counts can be used to determine actual population size through a mathematical model and have been projected forward to 2016. This model provides an estimated UK population for 2016 of 141,000 (95% CI = 117,500 - 168,500; SCOS, 2017).

239. In addition to counts of grey seal pups during the breeding season, grey seal are also counted during harbour seal surveys. The most recent counts of grey seal in the August 2016 surveys estimated that the total count of grey seals in the UK was 40,662 (SCOS, 2017).

240. In Ireland, the grey seal population was estimated to between 7,284 and 9,365 individuals, during the 2009-2012 monitoring program at seven main breeding sites (O'Cadhla *et al*., 2013).

12.5.6.2.1. South and West England and Wales Management Unit

241. Grey seal population size is normally derived from the numbers of pups born during their autumn breeding season. Grey seal distribution during their breeding season is, however, very different to their distribution at other times of the year. For this reason, the numbers of grey seal pups born in the autumn is provided as well as the summer counts of grey seals for each MU (IAMMWG, 2013).

242. In the South and West England and Wales MU, the grey seal pup production (autumn) was 1,900 with an estimated summer population size of 6,000, based on summer survey counts 1994-2003 and 2007 (SCOS, 2017; IAMMWG, 2013; **Table 12-19**). However, IAMMWG (2013) note that the South and West England and Welsh count is less certain due to infrequent assessment over this large area.

12.5.6.2.2. Wales

243. The colonies around the coast of Wales are rarely monitored. The most recent estimate for pup production in 2014 at Welsh colonies was 1,650 (SCOS, 2017). It is estimated that 96 pups were born in North Wales, 465 in North Pembrokeshire and 379 on Skomer and nearby mainland (Stringell *et al*., 2014; Strong *et al*., 2006).

244. Haul-out sites in Anglesey and the Llŷn Peninsula surveyed in 2014 had a count of 96 pups. Based on this count, there are an estimated 242-307 grey seal pups in the whole of north Wales (Stringell *et al*., 2014).

245. Recent surveys of grey seal pup production in North Wales was conducted in Autumn 2017 between Aberystwyth and the Dee Estuary (Clarke *et al*., 2018). The results show that 279 individual pups were born across 79 active nursery sites throughout the season. This suggests an approximate increase in pup production of 180% and a 145% increase in the number of nursery sites in comparison to the last full census of grey seal pups in North Wales in 2004 (Clarke *et al*., 2018).

246. Based on August counts (2011-2015) of grey seals at haul-out sites in Wales there are an estimated 422 grey seal and an estimated 480 grey seal in south-west England (SCOS, 2017). However, there are no dedicated seal surveys in these areas and only sparse information is available, therefore, estimates are compiled from counts from various different sources (SCOS, 2017). In addition, it should be noted that grey seal summer counts are known to be more variable than harbour seal summer counts and therefore caution is advised when interpreting these numbers (SCOS, 2017).

12.5.6.2.3. Seal Density Maps

247. As outlined above, SMRU has produced maps of grey seal distribution in UK waters (Russell *et al*., 2017). The grey seal density estimate of 0.155 per km^2 for the MDZ has been calculated from the seal density maps (**Figure 12-2, Volume II**; **Table 12-19**), based on the highest density estimate for the grid squares within 2 km of the area. There is currently insufficient data from the site-specific surveys to provide robust density estimates, therefore the latest seal at sea density maps (Russell *et al*., 2017) have been used to estimate the density of grey seal for the

MDZ. This was agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

Table 12-19 Grey seal abundance and density estimates

Area	Abundance Estimate	Density Estimate	Source
South and West England and Wales MU	**6,000**	N/A	IAMMWG (2013)
Morlais site	N/A	**0.155/ km^2**	Russell *et al*. (2017)
OSPAR Region	40,223 (9,997 – 7,4105)	0.10/ km^2 (0.02 – 0.18)	Russell *et al*. (2017)

12.5.6.3. Movements and Foraging Ranges

248. Grey seals forage in the open sea and they may range widely to forage and frequently travel over 100 km between haul-out sites (SCOS, 2017). Foraging trips can last anywhere between one and 30 days. Tracking of individual grey seals has shown that most foraging probably occurs within 100 km of a haul-out site, although they can feed up to several hundred kilometres offshore (SCOS, 2017).

249. Telemetry data show much individual variability in the movement patterns of grey seals (Matthiopoulos *et al*., 2004; McConnell *et al*., 1999), with some animals ranging widely and spending time in a variety of locations; while others remain in one limited area for most of the time they were tagged.

250. Grey seals from telemetry studies off western Scotland and off northern France indicate that the tagged grey seals from these areas did not enter the Irish Sea (Matthiopoulos *et al*., 2004). Tagging data of grey seals from haul-out sites in Liverpool Bay, Wales and southeast Ireland, indicates that most movement from these sites was contained within the Irish Sea (Hammond *et al*., 2005).

251. SCOS (2014) described telemetry studies that have been undertaken by tagging grey seals at five SACs across the UK (Pembrokeshire Marine, Lleyn Peninsula and the Sarnau, Monach Islands, Isle of May, and Berwickshire and North Northumberland Coast). The results indicate that grey seal travel between Sir Benfro Forol/Pembrokeshire Marine SAC, Pen Llyn a'r Sarnau/Llyn Peninsula and the Sarnau SAC and the Saltee Islands SAC (Ireland).

252. Data from tagging studies in the Irish Sea were examined in order to describe the extent of ‘forging trips’ of grey seals in the Irish Sea (SCOS, 2014). The telemetry data included in this study were from adult grey seals tagged at Ramsey (n=7), Bardsey (n=4), and Hilbre island (n=7) in 2004 and from pups tagged at Anglesey in 2009 and 2010 (n= 3 and 5), Bardsey in 2009 (n=2) and Ramsey in 2010 (n=7).

253. Over the lifetime of the tags, pups made an average of 58 trips per seal (over the average tag duration of 151 days) with a median trip duration of 0.92 days (95% CI = 0.12-7.89) between haul-out locations and covered an average distance of 19.47 km. The greatest distance travelled by one pup was 435.8 km. Grey seal adults made less trips with an average of 41 trips per seal (over the average tag duration of 131 days) and covered less distance (average maximum of 16.94 km), with trips between haul-out locations lasting on average 0.75 days (as a median, 95% CI = 0.12-5.61). The greatest distance travelled by one adult was 172.6 km.

The tag data showed that seals often move between haul out locations, in particular between the Lleyn Peninsula, Cardigan Bay and haul out locations around the Isle of Anglesey.

12.5.6.4. Haul-Out Sites

254. Grey seals spend longer hauled out during their annual moult between December and April, generally three and five months after the breeding season and during the breeding season between August and December (SCOS, 2017).

255. Around Wales, the breeding and pupping season for grey seal is between August and December with a peak in October-November, but this is extending. Pups are typically weaned 17 to 23 days after birth, when they moult their white natal coat and then remain on the breeding colony for up to two or three weeks before going to sea (SCOS, 2017).

256. The main breeding and haul-out sites for grey seal in Wales are located at the Skerries (11 km northeast of the MDZ and cable route), East Mouse (28 km northeast of the MDZ and cable route), Puffin Island (52 km east of the MDZ and cable route), Bardsey Island (55 km south of the MDZ and cable route), Tudwals and Carreg y Trai (84 km southeast of the MDZ and cable route) and Skomer Island (176 km south of the MDZ and cable route). The location of these sites is shown in **Plate 12-11**.

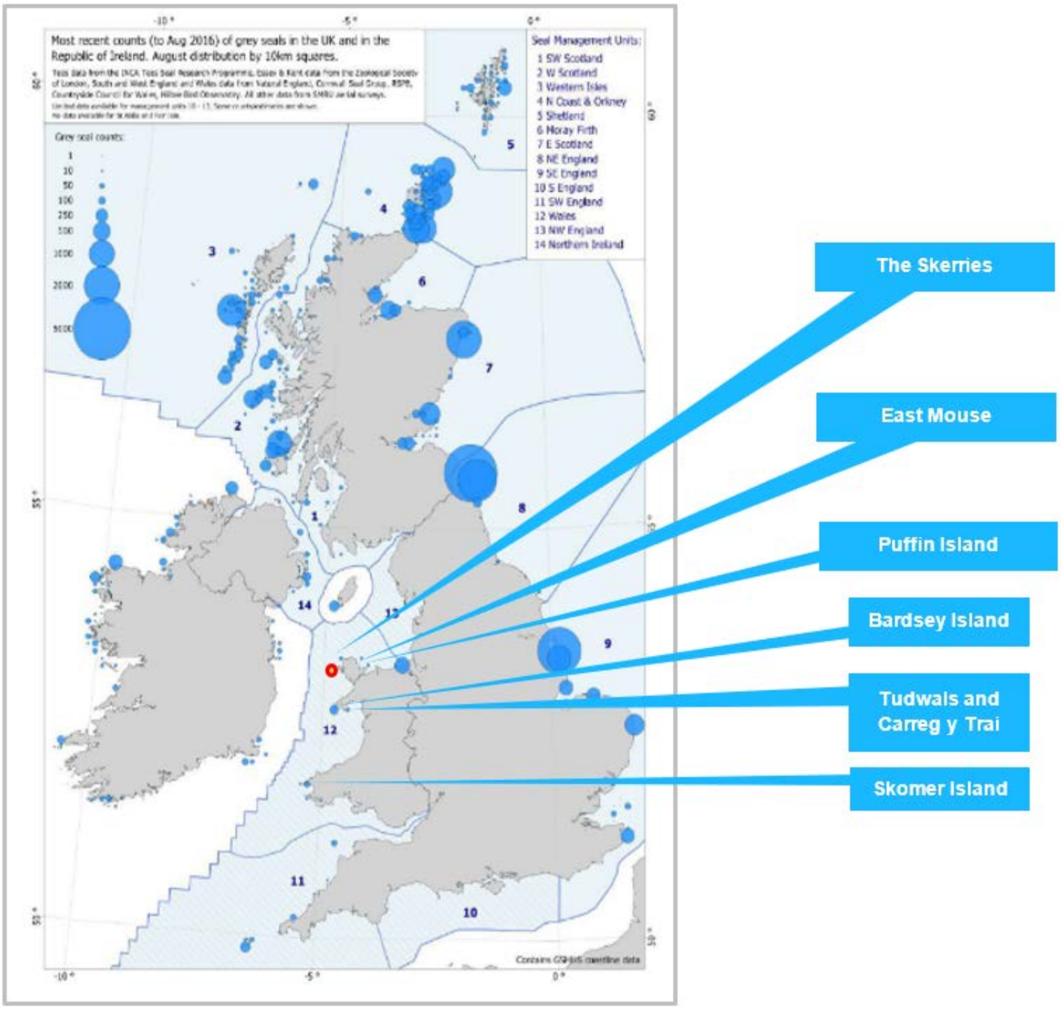

Plate 12-11 Grey seal haul out sites in Wales with MDZ indicated by red dot (source: SCOS, 2017)

257. In north Wales grey seal are known to use habitats such as intertidal rocky outcrops, beaches and sea caves that are tidally exposed. Breeding colonies in south-west England and in Wales are typically at the foot of steep cliffs or in caves and are therefore difficult to monitor (SCOS, 2017). During a grey seal haul-out site survey in Anglesey and the Llŷn Peninsula in 2014 (Stringell *et al*., 2014), an estimated 48% and 75% of pups born in Anglesey and the Llŷn Peninsula, respectively, were born in cave habitats (Stringell *et al*., 2014).

258. Recent surveys of grey seal pup production and distribution in North Wales conducted in Autumn 2017 between Aberystwyth and the Dee Estuary, identified 79 active nursery sites throughout the season (Clarke *et al*., 2018). The sites closest to the MDZ and cable area are indicted in **Figure 12-3** (**Volume II**) with the distances to these sites presented in **Table 12-20**.

Table 12-20 Distance to grey seal pupping sites near the MDZ and cable area (based on Clarke *et al.*, 2018)

Site Name	Distance to Cable Corridor (km)
Porth Namarch (West)	0.961
Porth Narach (East)	1.27
Yr Ogof Olaf	0.696
Porth y Nant	0.573
Ogof y Nant	0.554
Ogof Arw	0.338
Arw Cleft	0.069
Parliament House	0.22
Ogof Morlo	0.247
Ogof Migway (Yns Arw)	0.244
Ogof Ddeuddrws (Dream of White Horses)	0.300
Ofog Gogarth	0.549
Gof-du Big	2.306
Trearddur North	3.843

12.5.6.5. Diet

259. Grey seal are generalist feeders and will prey upon a variety of species. The most common food sources for grey seal are sandeels, gadoid species (such as cod, haddock, whiting and ling *Molva molva*) as well as flatfish species (such as plaice *Pleuronectes platessa*, sole *Soleidae sp.,* flounder and dab *Limanda limanda*), however this does vary from season and by location (Hammond and Grellier, 2006).

260. Food requirements for grey seal will depend on a number of factors, such as its size and fat content of the prey, but a general estimate is that a typical grey seal requires 4 to 7kg of prey a day, depending on the prey species (SCOS, 2017).

12.5.6.6. Conservation Status

239. The current conservation status of grey seal, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), is ‘favourable’ (JNCC, 2013).

12.5.7. Harbour seal

12.5.7.1. Distribution and Abundance

261. Harbour seals have a circumpolar distribution in the Northern Hemisphere and are divided into five sub-species. The population in European waters represents one sub-species *Phoca vitulina vitulina* (SCOS, 2017).

262. Harbour seals are counted on land during their August moulting period, which gives a minimum population estimate. Combining the most recent counts available (2008-2016) gives a total count of 31,300 harbour seals in the UK (25,150 of which are in Scotland), and scaling this to reflect the number of seals missed by not being hauled-out, gives a total UK population estimate of 43,500 (95% CI = 35,600-58,000) in 2016 (SCOS, 2017).

263. The most recent estimate of the harbour seal population in the Wales MU is less than 50 individuals (SCOS, 2017; **Table 12-21**). The most recent harbour seal count (2011-2016) for the Wales MU was five (SCOS, 2017). Point of Ayr is the only haul-out location for harbour seal in this MU is located approximately 98 km east of the MDZ and cable area. **Plate 12-12** shows the location of the major harbour seal haul-out sites around the UK and the most recent seal counts for each site.

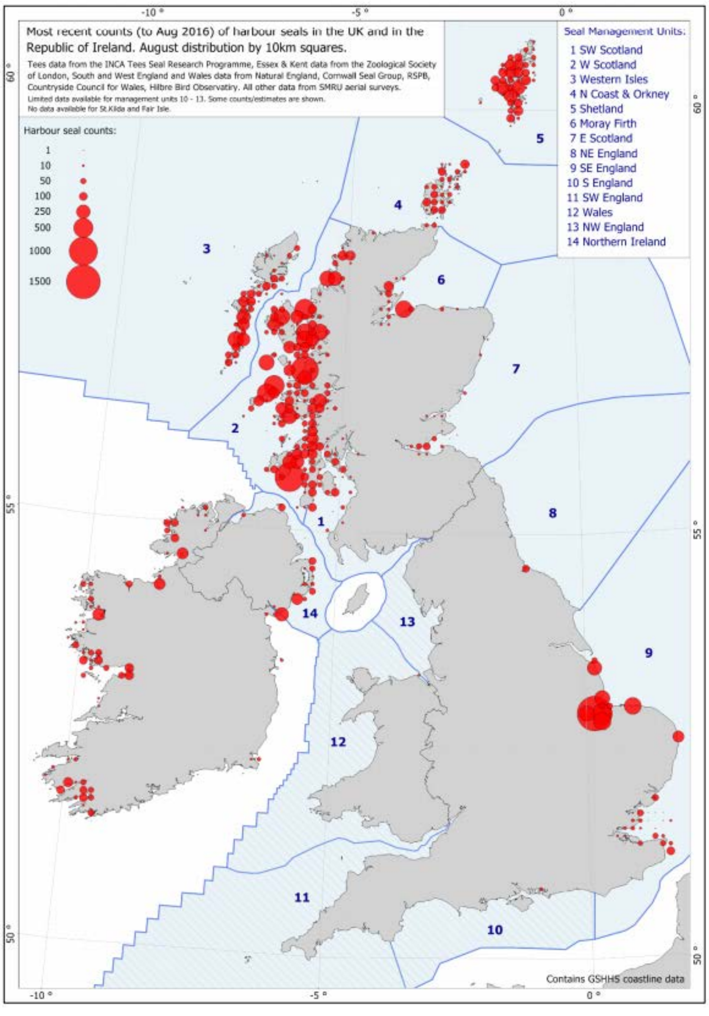

Plate 12-12 Location of the major harbour seal haul-out sites around the UK (source: SCOS, 2017)

264. It is noted in SCOS (2017) that very small numbers (<50) harbour seals are reported in the Wales MU are not included in this figure (SCOS, 2017). There are no systematic surveys for harbour seal in Wales.

265. The at-sea seal usage maps produced by SMRU show that the harbour seal usage is low in and around the MDZ, with a harbour seal density of 0.0005/ km^2 (**Figure 12-4, Volume II**; **Table 12-21**; Russel *et al*., 2017).

Table 12-21 Harbour seal abundance and density estimates

Area	Abundance Estimate	Density Estimate	Source
Wales	**50**	N/A	SCOS (2017)
Morlais site	N/A	**0.0005/ km^2**	Russell *et al*. (2017)
OSPAR Region	31,549 (13,217 – 50,218)	0.08/ km^2 (0.03 – 0.12)	Russell *et al*. (2017)

12.5.7.2. Movements and Foraging Ranges

266. SMRU, in collaboration with others, has deployed around 344 telemetry tags on harbour seals around the UK between 2001 and 2012 (Russell and McConnell, 2014). Spatial distributions indicate harbour seals persist in discrete regional populations, display heterogeneous usage and generally stay within 50 km of the coast (Russell and McConnell, 2014).

267. Harbour seals normally feed within 40 km and 50 km around their haul out sites (SCOS, 2017). Tracking studies have shown that harbour seal typically travel between 50 km and 100 km offshore and can travel 200 km between haul-out sites (Lowry *et al*., 2001; Sharples *et al*., 2012). Harbour seal exhibit relatively short foraging trips from their haul out sites. The range of these trips does vary depending on the surrounding marine habitat (e.g. 25 km on the west of Scotland; between 30 km and 45 km in the Moray Firth (Tollit *et al*., 1998; Thompson and Miller, 1990) and data from The Wash (from 2003- 2005)) suggest that harbour seal in this area travel further, and repeatedly forage between 75 km and 120 km offshore (with one seal travelling 220 km; Sharples *et al*., 2008).

268. Telemetry studies indicate that the tracks of tagged harbour seals have a more coastal distribution than grey seals and do not travel as far from haul-outs (Russell and McConnell, 2014).

269. The SMRU seal usage maps indicate there are small amounts of harbour seal usage around the north-east Irish coast, but no evidence of usage in the rest of the Irish Sea or along the Welsh coastline (Russell *et al*., 2017).

12.5.7.3. Haul-Out Sites

270. Harbour seal come ashore in sheltered waters, often on sandbanks and in estuaries, but also in rocky areas. Harbour seal haul out on land regularly in a pattern that is often related to the tidal cycle (SCOS, 2017).

271. Harbour seal give birth to their pups in June and July and pups can swim almost immediately after birth (SCOS, 2017). Harbour seals moult in August and spend a higher proportion of their time on land during the moult than at other times (SCOS, 2017).

12.5.7.4. Diet

272. Harbour seal take a wide variety of prey including sandeels, gadoids, herring and sprat, flatfish and cephalopods. Diet varies seasonally and regionally, prey diversity and diet quality also showed some regional and seasonal variation (SCOS, 2017).

273. It is estimated harbour seals eat 3-5 kg per adult seal per day depending on the prey species (SCOS, 2017).

12.5.7.5. Conservation Status

274. The current conservation status of harbour seal, as assessed in the 3rd UK report on implementation of the Habitats Directive (submitted to the European Commission in 2012), is 'Bad' (JNCC, 2013).

275. Harbour seals have been declining in recent years, with a loss of 21% of the UK population between 2000 and 2010 (JNCC, 2013). It was stated within JNCC (2013). that the reasons for the decline could potentially be down to shooting (under licence), bycatch, disturbance, dynamic positioning vessels (ducted propellers) or it could be bio-toxin related, competition with grey seals and predations by orca and grey seal (JNCC, 2013). More recent information describes only two of these factors as potential causes; interactions with grey seals and toxins from harmful algae (SCOS, 2017).

276. The decline was found predominantly in a few locations: Orkney with a population loss of 78% between 1978 and 2013; the east coast with a loss of 70% from 1997 to 2015; Firth of Tay loss of 92% from 2000 to 2015; and Shetland with a loss of 30% from 2000-2009 (this has now increased by 10% from 2009-2015) (SCOS, 2017). The population is now increasing again and is close to the levels before the decline described above.

12.5.8. European Designated Sites

277. All cetaceans in UK waters are classed as European Protected Species (EPS) under Annex IV of the Habitats Directive (EU Directive 92/43/EEC).

278. Bottlenose dolphin, harbour porpoise, grey seal and harbour seal are listed under Annex II of the Habitats Directive and are afforded protection through the designation of Natura 2000 (SAC) sites.

279. The HRA screening for the Project (**Document MOR/RHDHV/DOC/0067**) identified the following European Designated Sites for further assessment in the HRA:

- Gogledd Môn Forol/North Anglesey Marine SAC for harbour porpoise;
- Pen Llŷn a'r Sarnau/Llŷn Peninsula and the Sarnau SAC for bottlenose dolphin and grey seal;
- Gorllewin Cymru Forol/West Wales Marine SAC for harbour porpoise;
- Bae Ceredigion/Cardigan Bay SAC for bottlenose dolphin and grey seal;
- Dynesfeydd Môr Hafren/Bristol Channel Approaches SAC for harbour porpoise;

- Sir Benfro Forol/Pembrokeshire Marine SAC for grey seal;
- North Channel SAC for harbour porpoise;
- The Maidens SAC for grey seal;
- Rockabill to Dalkey SAC for harbour porpoise;
- Lambay Island SAC for harbour seal; and
- Saltee Islands SAC for grey seal.

280. These sites were determined based on:

- The European Designated Sites within the relevant MU area for each species;
- The potential for connectivity between individual marine mammals from European Designated Sites and the potential effects from the project (i.e. demonstration of a clear source-pathway-receptor relationship); and
- The potential for a realistic pathway for a possible effect on European Designated Sites for marine mammals.

281. The European Designated Sites are assessed further in the information to support the HRA (**Document MOR/RHDHV/DOC/0067**).

282. For harbour porpoise any European Designated Sites located more the 400 km from the Project in the Celtic and Irish Seas MU, it was determined that the potential did not exist for a LSE to arise and are therefore screened out of further assessment. Harbour porpoise are highly mobile. However, they have relatively high daily energy demands and it has been estimated that they can only rely on stored energy (primarily blubber) for three to five days, depending on body condition (Kastelein *et al*., 1997). Based on a swimming speed of approximately 1.5m/s (Otani *et al*., 2000), it is estimated that harbour porpoise could cover a distance of approximately 400 km in three days. In light of the above, it is highly unlikely that harbour porpoise from European Designated Sites located 400 km or more from the Project are dependent on the MDZ area. Although harbour porpoise from European Designated Sites more than 400 km away could have foraging ranges that overlap the MDZ, any potential indirect effects on prey are highly unlikely to have a significant effect on harbour porpoise from that European Designated Site.

283. For bottlenose dolphin, connectivity was considered possible between the Project and the two European Designated Sites within the Irish Sea MU.

284. Based on the foraging ranges for grey seal and the assessment of the telemetry data in and around the Irish Sea, it was determined that there was potentially connectivity for any European Designated Site for grey seal up to 200 km from the Project. Consequently, all European Designated Sites for grey seal beyond 200 km of the Project in the OSPAR region were not assessed further.

285. Based on the foraging ranges for harbour seal, it was determined that there was potential connectivity for any European Designated Sites for harbour seal up to 100 km of the Project. Consequently, all European Designated Sites for harbour seal beyond 100 km of the Project in the OSPAR region were not assessed further.

12.5.9. Anticipated Trends in Baseline Conditions

286. The existing baseline conditions for marine mammals as described in **Section 12.5** are considered to be relatively stable. The baseline environment of the Celtic and Irish Seas areas has been influenced by fishing by various methods for hundreds of years, coastal and harbour developments and the construction and operation of offshore wind farms for over ten years (for example, North Hoyle, Rhyl Flats and Burbo Bank). The baseline will continue to evolve as a result of global trends which include the effects of climate change.

287. For harbour porpoise, the observed distribution of harbour porpoises during the SCANS-III survey in 2016 was similar to that observed in SCANS-II in 2005, but one notable difference was more sightings were made throughout the English Channel (block C) in 2016 than previously (Hammond *et al*., 2017). Similarly, the observed distribution of bottlenose dolphin and common dolphin in 2016 was also similar to that observed during the SCANS-II and CODA surveys in 2005/07 (Hammond *et a*l., 2017).

288. Feingold and Evans (2014b), indicated that the low abundance values within Cardigan Bay SAC in 2012 and 2013, the lowest since monitoring began in 2001, may represent a shift in usage by the dolphins in the region since in recent years, bottlenose dolphin sightings have been reported regularly for the first time during summer months in North Wales, particularly around the Isle of Anglesey but extending east into Liverpool Bay and north to at least the Isle of Man.

289. The number of grey seal pups throughout Britain has grown steadily since the 1960s; when records began and there is clear evidence that the population growth is levelling off in all areas, except the central and southern North Sea where growth rates remain high (SCOS, 2017). Surveys of grey seal pup production and distribution in North wales in 2017 indicates an increase in pup production of 180% and a 145% increase in the number of nursery sites in comparison to the 2004 surveys (Clarke *et al*., 2017).

290. The potential impacts of climate change on marine mammals can be direct, such as the effects species tracking a specific range of water temperatures in which they can physically survive, or indirect effects, which could include changes in prey availability affecting distribution, abundance and community structure (Learmonth *et al*., 2006).

291. There is potential evidence of the effects of climate change on the composition and structure of cetacean communities off north-west Scotland (MacLeod *et al*., 2005). Analysis of strandings from 1948 to 2003 found that no new cetacean species per decade were recorded in north-west Scotland between 1965 and 1981, however, this rose to two new species per decade from 1988 onwards. The new species recorded since 1988 are generally restricted to warmer waters, while those recorded prior to 1981 regularly occur in colder waters. In the period 1992 to 2003, the relative frequency of stranding of white-beaked dolphin, a colder water species, had declined while stranding of common dolphin, a warmer water species, had increased. Similarly, sightings surveys conducted in May–September 2002 and 2003 show that the relative occurrence and abundance of white-beaked dolphins declined and common dolphins increased in comparison to previous studies. These observations are consistent with changes in the local cetacean community being driven by increases in local water temperature (MacLeod *et al*., 2005).

292. In a wider context, such changes may lead to populations of cetaceans moving out of areas specifically designated for their protection as they respond to changes in local oceanic conditions.

12.5.10. Summary of Marine Mammal Reference Populations and Density Estimates

293. **Table 12-22** summarises the reference populations and density estimates that are used to inform the assessments for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal. These were agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

Table 12-22 Reference populations and density estimates to inform the impact assessment for marine mammals

Species	Density Estimate (per km^2)	Reference Population
Harbour porpoise	0.783/ km^2	104,695 (Celtic and Irish Seas MU; IAMMWG, 2015)
Bottlenose dolphin	0.02/ km^2	397 (Irish Sea MU; IAMMWG, 2015)
Risso's dolphin	0.031/ km^2	8,794 (Celtic and Greater North Sea MU population; Paxton *et al.* 2016).
Common dolphin	0.22/ km^2	56,556 (Celtic and Greater North Seas MU population; IAMMWG, 2015).
Minke whale	0.017/ km^2	23,528 (Celtic and Greater North Seas MU population; IAMMWG, 2015).
Grey seal	0.155/ km^2	6,000 (South and West England and Wales MU; IAMMWG, 2013). 40,233 grey seal in the wider OSPAR region (based on Russell *et al.*, 2017)
Harbour seal	0.0005/ km^2	50 (Wales MU; SCOS, 2017). 31,549 harbour seal in the wider OSPAR region (based on Russell *et al.*, 2017).

12.5.11. Sensitivity of Marine Mammal Populations in Welsh Waters

294. Sparling *et al*. (2015) provides a level of sensitivity for each MU for marine mammals in Welsh waters (as defined by IAMMWG, 2015), based on an appraisal of a number of features. The main factors that contribute to the sensitivity of a marine mammal population to impacts are the current population size and distribution, current and recent trends in demographic parameters (fecundity, juvenile and adult survival) and life history variables such as age at maturity and longevity. The ability to adapt to change and the degree of existing threats are also important.

295. **Table 12-23** provides the predetermined sensitivity for each MU from Sparling *et al*. (2015). As there is only a single MU of relevance to Wales, these are presented as a 'species' in the table.

296. Sparling *et al*. (2015) note that although other marine mammal species are present in Welsh waters and may be species of concern for some developments, it is expected that that for most developments, the primary species of concern will be harbour porpoise, grey seals and/or bottlenose dolphins. This is because these are the most abundant species in Wales and are the only marine mammal Annex II species present in Wales. Other species can include Risso's dolphins around Bardsey Island (Llŷn Peninsula) and common dolphins in the southwest of Wales (e.g. Outer Bristol Channel and Pembrokeshire).

Table 12-23 Sensitivity classification of Welsh marine mammal populations from Sparling *et al*. (2015)

Species	Sensitivity	Rationale
Harbour porpoise	Low	Large population Favourable condition (unknown whether stable or increasing) Moderately fast maturing species Moderately long lived Wide ranging species
Bottlenose dolphin	High	Small population Favourable condition (stable population) Moderately slow maturing Moderately long lived Not a highly mobile population
Common dolphin	High in some areas, such as the outer Bristol channel	Moderately large population Favourable condition (stable population) Moderately slow maturing species Moderately long lived Wide ranging species
Grey seal	Low	Moderately large population Favourable condition (increasing population) Moderately fast maturing species Moderately long lived Wide ranging species

297. Based on the sensitivity classification of the marine mammal populations by Sparling *et al*. (2015) in **Table 12-23**, the sensitivity of marine mammal populations to potential impacts for the proposed Morlais Project have been considered, for context only, as:

- Low for harbour porpoise, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal; and
- High for bottlenose dolphin.

298. However, the sensitivity for the assessments has been based on the impact assessment matrix approach, as outlined in **Section 12.4.4.1**.

12.6. IMPACT ASSESSMENTS

12.6.1. Overview of Potential Impacts for Marine Mammals

299. The following section provides an overview of all impacts identified during scoping study and those which have been determined as the EIA has progressed. Each impact may not be relevant to all stages of the project, and thus impacts have been assessed within the stage of the project at which they will occur (construction, operation, repowering and decommissioning). Further, these impacts are comprised of both direct and indirect impacts.

300. Impacts are classified as follows:

- Direct impacts: these may arise from impacts associated with the construction, operation and maintenance, repowering or decommissioning of the project;
- Indirect impacts: these may be experienced by a receptor that is removed (e.g. in space or time) from the direct impact (e.g. noise impacts upon fish which are a prey resource for marine mammals).
- Inter-relationships between impacts; or cumulative impacts: these may occur as a result of the project in conjunction with other existing or planned projects within the study area for each receptor.

301. The potential impacts assessed for marine mammals are:

1. During Construction, Installation and Repowering:

- Underwater noise and disturbance:
  - Installation tidal devices and hubs (for example, drilling of foundations);
  - Construction activities (such as, cable installation and cable protection); and
  - Vessels;
- Potential barrier effects from underwater noise during construction;
- Disturbance at haul out sites (for example, from vessels moving to and from the site and at cable landfall);
- Increased collision risk with vessels;
- Potential changes in water quality (for example, increased suspended sediments, or any accidental release of contaminants); and
- Potential changes in prey availability (for example, underwater noise, disturbance, temporary loss of seabed habitat, increased suspended sediment concentrations and sediment re-deposition).

2. During Operation, Maintenance and Repowering:

- Underwater noise and disturbance:
  - Operational tidal devices;
  - Maintenance and repowering activities (such as, cable re-burial and additional cable protection; removal and replacement of devices / array);
  - Vessels; and
  - Acoustic Deterrent Devices (ADDs), if required;
- Collision risk with tidal devices;
- Increased collision risk with vessels;
- Potential entanglement with moorings for floating devices;
- Potential electromagnetic fields (EMF) effects;
- Potential barrier effects;

- Potential changes in water quality (for example, any accidental release of contaminants); and
- Potential changes in prey availability (for example, underwater noise, disturbance, loss of seabed habitat, introduction of hard substrate (e.g. foundations, cable and scour protection), changes to water quality and EMF.

3. Decommissioning:

- Underwater noise and disturbance;
- Increased collision risk with vessels;
- Potential changes in water quality; and
- Potential changes in prey availability.

4. Potential Cumulative Impacts and In-combination Effects:

- Underwater noise and disturbance;
- Collision risk; and
- Potential changes in prey availability.

12.6.2. Embedded Mitigation

302. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible.

303. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process (see **Chapter 4, Project Description** for further details). A range of different information sources has been considered as part of embedding mitigation into the design of the project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

304. Embedded mitigation relevant to Marine Ornithology is as follows;

- The PDE for tidal devices defined using parameters available from established tidal device technologies, which has been assumed will be developed sufficiently for commercial use at time of deployment. These have been incorporated in the modelling outlined in **Section 12.6.4.5.1**.

12.6.1. Worst-Case Scenarios

305. The realistic worst-case parameters for each category of potential impact (as outlined in **Table 12-25 Section 12.6.1.4**) has been determined. This takes into account the Project Design Envelope (PDE) and tidal devices that could be deployed, as outlined in **Chapter 4, Project Description**.

306. For this assessment, the realistic worst-case scenario involves consideration of both the timing of impacts, as well as the physical parameters that define the PDE. The worst-case scenario

for each potential impact is outlined in **Table 12-25**. Further details on the project design are presented in **Chapter 4, Project Description**.

307. The realistic worst-case scenarios identified here also apply to the Cumulative Impact Assessment (CIA). When the worst-case scenarios for the project in isolation do not result in the worst-case for cumulative impacts, this is addressed within the cumulative section of this chapter (see **Section 12.6.6**).

12.6.1.1. Construction

12.6.1.1.1. Tidal Device and Infrastructure Foundation Systems and Installation Methods

308. As outlined in **Chapter 4 Project Description**, there are two types of foundation systems proposed within the MDZ; seabed mounted and anchored / moored systems.

309. Seabed mounted foundations include:

- Gravity Based Structures (GBS):
  - The footprint (the element of the foundation in direct contact with the seabed) of gravity foundations, proposed at the MDZ would typically be very small (<10m^2), with gravity bases often using 'feet' that focus the weight of the foundation on a small area of seabed.
- Multi-piled Structures (including tripod and quadrapod):
  - A tripod or quadrapod structure typically using three or four pin-piles. A socket is drilled into the seabed and the pin-pile is inserted into the socket and grouted into place.
- Monopiles:
  - Monopiles may also be utilised within the MDZ, primarily for the electrical hub infrastructure.

310. Anchored / moored foundation systems include:

- Catenary moorings with four GBS as anchors.
- Tension mooring system with four GBS as anchors.

311. Installation methods for these foundation systems include:

- Drilling for multi-piles and monopile foundations:
  - Due to the hard substrate (bedrock) in the MDZ, drilling will be required to install piled foundations.
- Gravity based foundations and anchors.

312. In addition to the tidal devices, other infrastructure at the site will include:

- Electrical hubs (seabed mounted fully submerged hubs; floating surface emergent hubs; or seabed mounted surface emergent hubs);
- Navigational and mooring buoys;

- Acoustic Doppler Current Profilers (ADCPs);
- Seabed mounted environmental monitoring platforms; and
- Floating environmental monitoring platforms.

313. The hubs could have drilled piled foundations while the other infrastructure would have GBS or anchor foundations, rather than requiring drilled piled foundations.

314. For the main installation phase of tidal devices and associated electrical hub infrastructure, the typical time for complete installations is between three and 15 days per device, including foundation installation.

315. For the tidal device installation, it is estimated there could be up to a total of 4,306 days required. However, in practice it will most likely be done by up to three separate vessels working in parallel.

316. For the hub installation, it is estimated there could be up to a total of 1,800 days required, based on up to 15 days per hub for 120 hubs. However, hub installation would be conducted in parallel with the inter-array cable installation.

317. The other infrastructure (navigational and mooring buoys and ADCPs) would be installed during the tidal device and hub installation periods.

12.6.1.1.2. Offshore Cables

318. Up to nine export cables will be installed between the MDZ and the shore. The individual cable route lengths are predicted to range between 1.2 km and 6 km. For the export cable installation, it is anticipated that each of the nine export cables would take up to 20 days installation (total of 180 days), plus up to 108 days for export cable protection installation

319. Inter-array cables will be laid between the tidal devices and hubs. For the full 240MW capacity, there could be up to 740 individual array cables, with a maximum length of 2.5 km per cable, but the majority of cables being less than this (<1 km). The total length of array cables will up to 204.5 km. Total installation duration for all the inter-array cables would be up to 1,110 days, based on up to 1.5 days per cable. It is assumed that two arrays would be installed in parallel.

320. Due to the hard and rocky nature of the seabed, it is expected that the majority of the cables will be free laid with strategic protection (rock bags or concrete mattresses) at locations along the length. Where burial may be possible this will be done using jet trenching. However, this will have to be confirmed by pre-installation geotechnical site investigations informing detailed design.

12.6.1.1.3. Offshore Construction Schedule

321. Offshore works (for installation of tidal devices and associated cabling and infrastructure) would be phased over a period of up to ten years (see **Chapter 4 Project Description** for further details).

322. The offshore construction schedule has been determined based on the number of days vessels could be required to be on site for each stage of construction, this is summarised in **Table 12-24**.

Table 12-24 Installation durations

Construction Stage	Predicted number of vessels on site	Indicative number of days vessels on site during 10 year construction	Indicative number of days vessels on site per year	Indicative number of days vessels on site per year	% of time vessels on site per year
Cable tail installation	3 vessels (1 x cable tail installation vessel; 1 x cable tail installation support vessel; and 1 x dive support vessel)	20 days (assumes single operation of up to 15 days with 5 days extra for protection)	20 days	N/A (works in nearshore area)	5.48%
Export cable installation	2 vessels (1 x cable installation vessel; and 1 x support vessel)	180 days (assumes 9 blocks of 20 days over 10yr period)	20 days (worst-case assumes that one 20 day block of activity occurs per year, for 9yrs of the 10yr build-out period)	Each 20 day block of export cable installation per year	5.48%
Export cable protection installation	3 vessels (1 x cable tail installation vessel; 1 x cable tail installation support vessel; and 1 x dive support vessel)	108 days (assumes 9 x blocks of 12 days following each block of export cable installation)	12 days (worst-case assumes that one 12 day block of activity occurs per year, for 9 yrs of the 10yr build-out period)	Each 12 day block of export cable protection installation per year	3.29%
Inter-array cable Installation	2 vessels (1 x cable installation vessel; and 1 x support vessel)	775 days (assumes a 10 year period build out of all 8 arrays, and no more than 2 arrays built in parallel at any time)	77.5 days	Up to 10 days	21.23%
Hub installation	2 vessels (1 x hub installation vessel; and 1 x support vessel)	1,800 days (assumes 15 days per hub for 120 hubs)	180 days	22.5 days	49.32%
Tidal device installation	2 vessels (1 x construction vessel; plus 1 support vessel) Or 4 vessels (2 x construction vessel; plus 2 support vessel)	4,306 days	431 days	54 days	100% & 18% (assumes 1 x construction vessel plus 1 support vessel on sites every day; plus for 18% of year assumes 2 x construction vessel plus 2 support vessels on site)

12.6.1.2. Operation, Maintenance and Repowering

12.6.1.2.1. Tidal Devices

323. The tidal devices which may be installed under the Project Design Envelope have the following key elements, common across all device types:

- Tidal Energy Converter (TEC) or converters;
- Foundations, anchors or moorings on the seabed;
- Substructures supporting the TECs; and
- Cable connections.

324. Tidal devices currently being considered can be placed in three broad categories:

- Seabed mounted and submerged;
- Buoyant and mid-water column; and
- Surface floating.

325. The TECs could be:

- Horizontal axis (axial flow) rotors; or
- Vertical axis (cross flow) rotors.

326. A number of other device categories have been excluded from further consideration following a review of device types, technologies (see **Chapter 4 Project Description** for further details), these include:

- Surface piercing seabed mounted tower;
- Large seabed mounted cross-flow, horizontally orientated;
- Ducted cross-flow; and
- Other novel designs.

327. Further details on the parameters used in the collision risk assessment for the tidal devices are provided in **Section 12.6.4.5.1**.

12.6.1.2.2. Tidal Array Layout

328. As outlined in **Chapter 4, Project Description**, the final array layout will be identified post consent, following the berth selection and allocation process. The final detailed device locations will be developed based on further site investigation works conducted post-consent to determine detailed construction constraints.

329. Seabed mounted devices (Category 1) may have a spacing of 70 m to 150 m between centres of devices perpendicular to the flow and 180 m to 25 0m parallel to the flow. Such spacings may need to be modified to allow for seabed conditions, and this could alter spacings considerably, resulting in larger spacings.

330. The maximum case in terms of spacing would be floating tidal devices sharing moorings (Category 3). Such devices may require up to 150 m between structure centres perpendicular to the flow and 250 m parallel to the flow.

331. Each device could move by up to 80 m (±40 m) in the direction parallel to the flow and 60m (±3 0m) in the direction perpendicular to the flow. Therefore, the overall surface area covered by device movement (including device yawing) is up to 4,800 m^2 for a single floating device (Category 3).

332. This equates to a maximum area taken up by all arrays, including spaces between devices (i.e. not the seabed footprint) of up to 12.5 km^2 (up to 35% of the MDZ array area of 35 km^2) for the full 240MW capacity project.

333. Indicative layouts are presented in **Chapter 4 Project Description**.

12.6.1.2.3. Maintenance and Repowering Activities

334. As outlined in **Chapter 4 Project Description**, typical maintenance jobs may include: diagnostic tests, oil changes and lubrication, replacement of control cards and sensors, removal of biofouling, overhaul or replacement of systems (gearboxes, generators, switchgear etc.). Major operations such as retrieval and repair following structural failures would require similar vessels and procedures as installation works.

335. The project is a tidal technology demonstration project and it is anticipated that the tidal devices/arrays may be replaced several times within the project life time.

336. A repowering of a device/array is defined as the end of a berth/array demonstration cycle, at which time the TECs, device foundations, support structures, electrical hubs, tenant monitoring equipment, and inter-array cabling will be removed and replaced.

337. As a worst-case scenario, maintenance and repowering activities have been based on the assessment for construction. Because both maintenance and repowering (assumed at 50% of construction) are less than initial construction, this assessment is conservative.

12.6.1.3. Decommissioning

338. Assumed to be no greater than during construction phase.

12.6.1.4. Worst-Case Parameters

339. The worst-case scenario for each potential impact is outlined in **Table 12-25**.

Table 12-25 Worst-case parameters for marine mammal assessments

Project Phase	Impact	Parameter	Maximum worst-case	Notes
Construction	Underwater noise for foundation	Number of tidal devices requiring drilled foundations	Up to 620	Up to 620 small (less than 300kW) devices; or Up to 240 large 1MW+ devices

Project Phase	Impact	Parameter	Maximum worst-case	Notes
	installation – drilling			Up to 180 surface piercing devices (large or small) Maximum of 30MW of any one device in an array (maximum of 150 devices)
		Number of hubs requiring drilled foundations	Up to 120	60 hubs (each with 3 x 2.6m diameter piles); plus 60 hubs (each with 4 x of 2.6m diameter piles)
		Maximum number of piles for tidal devices	3,675	80 devices (each with 4 x 2.6m diameter piles); plus 120 devices (each with 4 x 1.2m diameter piles); plus 90 devices (each with 3 x 2.6m diameter piles)
		Maximum number of piles for hubs	420	
		Maximum pile diameter	2.6m	
		Total maximum duration of drilling for tidal device foundations	2,730 days	The duration to drill each pile could be up to 2 days for 1.2m diameter piles and up to 3 days for 2.6 diameter piles. 80 devices (each with 4 x 2.6m diameter piles) x 3 days = 960 days; plus 120 devices (each with 4 x 1.2m diameter piles) x 2 days = 960 days; plus 90 devices (each with 3 x 2.6m diameter piles) x 3 days = 810 days
		Total maximum duration of drilling for hub foundations	1,260 days	60 hubs (each with 3 x 2.6m diameter piles) x 3 days = 540 days; plus 60 hubs (each with 4 x of 2.6m diameter piles) x 3 days = 720 days
		Total maximum duration of drilling for tidal device and hubs foundation installation	Up to 3,990 days for 1,490 drilled piles	2 days for each of 120 x 1.2 m diameter drills and 3 days each for other diameter drills.
		Number of concurrent foundation installations (drilling events)	2	Up to two deployment areas could be developed at the same time.
	Underwater noise from	Cable installation method	Surface laid with strategic protection.	Underwater noise potentially greater during jet trenching.

Project Phase	Impact	Parameter	Maximum worst-case	Notes
	cable installation		Jet trenching where possible.	
		Cable protection	Rock bags or concrete mattresses.	Underwater noise during placement of cable protection
		Duration of cable installation	1,310 days	Export cables = 180 days Inter-array cables = 1,110 days Cable tails = 20 days
		Duration of cable protection	Up to 108 days	Export cable protection: 9 x blocks of 12 days, to begin up to 1 month after commencement of export cable laying
		Number of concurrent cable installations	2	Up to two deployment areas could be developed at the same time.
	Underwater noise and disturbance from vessels	Number of vessels	Up to 16 vessels	See **Table 12-24**. Maximum is likely to be 14 vessels at any one time, but based on up to 16 as worst-case scenario.
		Cable tail vessel days	Up to 20 days	Assume as one operation of 20 days duration.
		Export cable vessel days	Up to 180 days	Assumes 9 x blocks of 20 days, with each block continuous, but the 9 blocks spread across a possible 5 year period (may be longer, perhaps much, but not shorter) build out to 240MW.
		Cable protection vessel days	Up to 108 days	Assumes 9 x blocks of 12 days, to begin up to 1 month after commencement of export cable laying
		Inter-array cable vessel days	Up to 775 days	Assuming a minimum 10 year period build out, 8 arrays, and no more than 2 arrays built in parallel at any time. 194 vessel days per array. Therefore, 774.5 days over the 3650 days (10 years) assuming 2 arrays in parallel up to 1,549 days over 3,650 days assuming in sequence.
		Hub installation vessel days	Up to 1,800 days	1,800 days across a 3,650 day period. Hubs and arrays will be installed in parallel.
		Tidal device installation days	4,306 days	4,306 days across a 3,650 day period.
		Note: Number of vessel days is not the sum of all these values as many installation operations will take place in parallel.		
	Barrier effects from	Maximum potential area and duration of underwater during construction.		

Project Phase	Impact	Parameter	Maximum worst-case	Notes
	underwater noise			
	Disturbance at seal haul-out sites	Distance of construction activities, vessels and landfall from seal haul-out and pupping sites.		
	Increased collision risk with vessels	Number of vessels	Up to 16 vessels on site	Increased risk from increased number of vessels during construction compared to baseline.
		Number of vessel trips	Up to 16 per day	Assumed worst-case that each vessel would move to and from the site each day. Increased risk from increased number of vessels movements during construction compared to baseline.
		Area	Up to 10.75 km^2	Based on construction vessels in two indicative largest potential deployment areas (3 km^2 + 3 km^2); plus, vessels in export cable corridor area (4.75 km^2).
		Vessel route area	4.34 km^2	Vessel route from Holyhead Port to MDZ and cable corridor, based on 250m buffer either side of vessel.
	Changes in water quality	Increased suspended sediments	117,780m^3	Based on a 240MW capacity, the worst-case volume of cuttings for the entire site. A single device requiring four drilled piles will produce 160m^3 of cuttings
		Accidental release of contaminants	7,000 vessel days	Approximately 7,000 vessel days throughout the duration of the construction phase
			For the liquid inventory of devices deployed within the MDZ, the following worst-case values have been assumed: Oil (gearboxes, transformers etc.) 240,000 litres; Grease (bearing, seals etc.) 12,000 litres; and Hydraulic fluid 192,000 litres.	
	Changes in prey availability	Underwater noise	Parameters as outlined above.	
		Temporary habitat loss during construction	0.42 km^2	Post-lay burial of cable = 27,259m^2 Deployment of anchor blocks by barges during cable installation = 100,240m^2 Deployment of anchor blocks by barges during TEC device installation = 248,000m^2

Project Phase	Impact	Parameter	Maximum worst-case	Notes
				Deployment of anchor blocks by barges during hub installation = 48,000m^2 (see Chapter 10 for details)
		Changes in water quality	Parameters as outlined above.	
Operation, Maintenance and Repowering	Collision risk with tidal devices	See **Section 12.6.4.5.1.**		
	Underwater noise and disturbance from operational tidal devices	Worst-case scenarios based on underwater noise modelling for PTEC. 90 dB_{ht}(*Species*) maximum range = 610m for harbour porpoise, 95m for dolphin species; 400m for minke whale and 75m for seal species.		
	Underwater noise and disturbance from maintenance and repowering activities	Although likely to be less than parameters assessed for construction. Assessment has been based on construction parameters as a worst-case scenario.		
		Export cable inspection	Annual inspections of the export cable for the first 2 or 3 years, reducing to every 2 years thereafter.	Inspection / maintenance = 15 single day events per year. Assumes that 10 are late spring, summer, early autumn. Other 5 are across rest of year.
		Device inspection	Device inspection up to 15 times annually (for both planned and unplanned maintenance activities).	
		Cable repairs	Up to 10 major cable repairs (5 days each) may be required throughout the project life. It is assumed that up to 750m of cable will be subject to repair works per event (7,500m in total).	Cable repairs – 10 x 5 days or 50 days across life of project. Assume project operation life is 25 - 35 years, then one event every 2.5 to 3.5 years
	Underwater noise and disturbance from vessels	Number of vessels	Up to 16 vessels on site	As a worst-case scenario, assessment based on construction parameters, although likely to be less. Annual inspections of all cables will occur for the first three years after installation, reducing to every two years thereafter. Up to ten major cable repairs of five days each may be required

Project Phase	Impact	Parameter	Maximum worst-case	Notes
				throughout the project life of 35 years. Devices will be visited up to 15 times annually. Approximately four groups of vessels may be present in the MDZ and ECC at any one time during the lifespan of the project, of which two would be in the MDZ, and two in the ECC.
	Acoustic Deterrent Devices (ADDs)	Potential area of disturbance	1 km	Based on ADD review (see **Section 12.6.4.4**).
		Duration of activation	10-20 minutes	
		Number of ADDs	Up to 40 ADDs	Indicative as will depend on final mitigation plan and requirements.
	Increased collision risk with vessels	Area	Up to 10.75 km^2	As for construction, based on vessels in two indicative largest potential deployment areas (3 km^2 + 3 km^2); plus, vessels in export cable corridor area (4.75 km^2).
		Vessel route area	4.34 km^2	Vessel route from Holyhead Port to MDZ and cable corridor, based on 250m buffer either side of vessel.
	Entangle-ment with moorings for floating devices	Mooring will either be via tensioned systems, or catenary anchors. No loose mooring cables anticipated.		
	Electromag-netic fields (EMF) from offshore cables	Cable area	0.042 km^2	Foot print of cables and protection systems: Export cables = 11,745m^2: Inter-array cables = 30,040m^2; and Offshore cable tails = 120m^2.
	Barrier effects	Physical structures	12.5 km^2 (up to 36% of the MDZ array area)	Maximum area taken up by all arrays, including spaces between devices (i.e. not the seabed footprint) of up to 12.5 km^2 (up to 36% of the MDZ array area of 35 km^2) for the full 240 MW capacity project.
	Changes in water quality	Accidental release of contaminants	Same as for construction	There is also the possibility of pollution incidents due to ejection of contaminants or accidents involving tidal devices, and/or vessels. Any discharge will be limited and rapidly dispersed in tidal environment.

Project Phase	Impact	Parameter	Maximum worst-case	Notes
		Increased suspended sediments from 50% of all devices replaced via repowering works.	124,000 m^2	Footprint of temp seabed disturbance via anchor barges = 124,000m^2 (50% of 248,000 m^2 of temp seabed disturbance via TEC installation in construction phase)
		Increased suspended sediments during cable repairs	3,000 m^2	Up to 10 major cable repairs (5 days each) may be required throughout the project life. It is assumed that up to 750m of cable will be subject to repair works per event (7,500 m in total). Using same value of 400 m^2 temp seabed disturbance per 1 km of cable works (400 x 7.5) = 3,000 m^2
	Changes in prey availability	Underwater noise	Parameters as outlined above.	
		Temporary habitat loss	0.12 km^2	50% of all devices replaced via repowering works = 124,000 m^2 Cable repairs = 3,000 m^2 (see **Chapter 10** for details)
		Permanent habitat loss	2.18 km^2	Based on area for Gravity Base Structures (GBS) (74,790 m^2), swept area of catenary cables (2,055,000 m^2), export cable footprint (cables and protection systems; 11,745 m^2), array cable footprint (cables and protection systems; 30,040 m^2), additional cable protection material (4,860 m^2), cable tails (120 m^2), trench for 9 x landfall cables (7,400 m^2), footprint of navigation marker buoys (540 m^2), footprint of Acoustic Doppler Current Profiler (ADCP) moorings (280 m^2), footprint of seabed mounted environmental monitoring units (112 m^2) and footprint of mooring for floating environmental monitoring units (45 m^2). (see **Chapter 10** for details)
		EMF effects	Parameters as outlined above.	
		Changes in water quality	Parameters as outlined above.	
Decommissioning	Underwater noise	Assumed to be no greater than during construction phase		

Project Phase	Impact	Parameter	Maximum worst-case	Notes
	Increased collision risk with vessels	Assumed to be no greater than during construction phase		
	Changes in water quality	Assumed to be no greater than during construction phase		
	Changes in prey availability	Assumed to be no greater than during construction phase		

12.6.2. Mitigation

12.6.2.1. Embedded Mitigation

340. Menter Môn has committed to several techniques and engineering designs/modifications inherent as part of the project, during the pre-application phase, in order to avoid a number of impacts or reduce impacts as far as possible. Embedding mitigation into the project design is a type of primary mitigation and is an inherent aspect of the EIA process. A range of different information sources has been considered as part of embedding mitigation into the design of the project including engineering preference, ongoing discussions with stakeholders and regulators, commercial considerations and environmental best practice.

341. Embedded mitigation in the project design stage has involved not including several types of devices, restrictions on the position in the water column for some devices and maximum potential number of devices due to the initial collision risk assessments.

12.6.2.2. Water Quality

342. Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. A Marine Pollution Contingency Plan (MPCP) would be in place and agreed with NRW in line with the Integrated Pollution Prevention and Control (IPPC) Directive such that any potential risk is minimised.

12.6.2.3. Proposed Approach to Marine Mammal Mitigation and Monitoring

12.6.2.3.1. Proposed Mitigation for Underwater Noise During Construction

343. Marine Mammal Mitigation Protocols (MMMPs) will be prepared to reduce the risk of any permanent auditory injury (Permanent Threshold Shift (PTS)) to marine mammals as a result of underwater noise during construction. The MMMP(s) will be developed in the pre-construction period and based upon best available information, methodologies, industry best practice, latest scientific understanding, current guidance and detailed project design.

344. The MMMP(s) will be developed in consultation with NRW and the relevant SNCBs, detailing the proposed mitigation measures to reduce the risk of any physical or permanent auditory injury (PTS) to marine mammals from underwater noise. This will include details of any embedded mitigation, as well as details of the mitigation zone and any additional mitigation measures required in order to minimise potential impacts of any physical or permanent auditory injury

(PTS), for example, the use of Marine Mammal Observers (MMOs), Passive Acoustic Monitoring (PAM) and / or activation of acoustic deterrent devices (ADDs). The methods for achieving the mitigation zone would be agreed with NRW and the relevant SNCBs.

345. It is currently proposed, that a MMMP for drilling activity would be prepared prior to construction, for example with the option of having MMOs on site during drilling activities to ensure marine mammals do not enter a predetermined mitigation zone (for example, 500m), based on the maximum potential PTS impact range, e.g. 210m for minke whale (see **Table 12-30**).

346. It is also proposed that a MMMP for cable installation and cable protection activities would be prepared prior to construction, for example with the option of having MMOs on site to ensure marine mammals do not enter a predetermined mitigation zone, based on the potential PTS impact range of up to 100m (see **Table 12-40**).

12.6.2.3.2. Proposed Mitigation and Monitoring for Collision Risk with Operational Turbines

347. The mitigation and monitoring plan to reduce the collision risk of marine mammals with operational turbines will be developed in the pre-construction period so that it can be based upon best available information, methodologies, industry best practice, latest scientific understanding, current guidance and detailed project design.

348. It will be developed in consultation with NRW and the relevant SNCBs, detailing the proposed mitigation measures which could include, but may not be limited to, detecting marine mammals in and around the arrays (this could be done using remotely monitored PAM, underwater cameras, autonomous recorders, and / or high definition (HD) and thermal imaging camera systems). There would also be the use of active sonar to detect marine mammals in close proximity to the arrays / devices which could be used to trigger mitigation measures, such as the automatic activation of ADDs to deter marine mammals from a predetermined mitigation zone around the arrays / devices.

349. The approach would be based on deployment, monitoring and adaptive management, with regular reviews of the installation at appropriate deployment increments directly related to collision risk to marine mammals, specifically bottlenose dolphin, to ensure that no more than one bottlenose dolphin could be theoretically at risk of collision or other significant impact.

350. An outline Environmental Mitigation and Monitoring Plan (EMMP) has been submitted with the ES (**Document MOR/RHDHV/DOC/0072**). The EMMP will develop alongside the development of the project, and the “proposed approach to the EMMP is that it will provide a flexible framework, through which further knowledge and understanding of the risks presented from the project that can be achieved throughout the project lifespan.” In addition, the EMMP will meet the project specific licence conditions.

351. The EMMP will focus on the potential collision risk of marine mammals and seabirds, as well as outlining the Marine Mammal Mitigation Plan (MMMP) for reducing the risk of any auditory injury in marine mammals as a result of underwater noise, which will be submitted as a separate document six months prior to construction.

352. The EMMP will be developed in consultation with NRW with a schedule of agreed milestones to meet the requirements prior to construction.

12.6.3. Assessment of Potential Impacts During Construction

12.6.3.1. Underwater Noise During Installation of Tidal Devices and Hubs

353. As outlined in **Chapter 4, Project Description** and **Section 12.6.1.1.1**, due to the hard substrate (bedrock) in the MDZ, drilling will be required to install pin-pile and monopiles foundations for the tidal devices and hubs. Of the potential installation methods that could be used, this has been considered as the worst-case scenario for underwater noise during the installation of the foundations for the tidal devices and hubs, compared to GBS and weighted anchors.

354. Underwater noise can cause both physiological (e.g. lethal, physical injury and auditory injury) and behavioural (e.g. disturbance and masking of communication) impacts on marine mammals (e.g. Bailey *et al*., 2010; Madsen *et al*., 2006; Thomsen *et al*., 2006, Thompson *et al*., 2010).

355. High exposure levels from underwater noise sources can cause auditory injury or hearing impairment taking the form of a permanent loss of hearing sensitivity (Permanent Threshold Shift (PTS)) or a temporary loss in hearing sensitivity (Temporary Threshold Shift (TTS)). The potential for auditory injury is not just related to the level of the underwater sound and its frequency relative to the hearing bandwidth of the animal, but is also influenced by the duration of exposure. The level of impact on an individual is a function of the Sound Exposure Level (SEL) that an individual receives as a result of underwater noise.

356. Marine mammals may exhibit varying intensities of behavioural response at different noise levels. These include orientation or attraction to a noise source, increased alertness, modification of characteristics of their own sounds, cessation of feeding or social interaction, alteration of movement / diving behaviour, temporary or permanent habitat abandonment, and in severe cases, panic, flight stampede or stranding, sometimes resulting in injury or death. The response can vary due to exposure level, the hearing sensitivity of the individual, context, previous exposure history or habituation, motivation and ambient noise levels (e.g. Southall *et al*., 2007).

- The potential impact of underwater noise will depend on a number of factors which include, but are not limited to:
- The source levels of noise;
- Frequency relative to the hearing bandwidth of the animal (dependent upon species);
- Propagation range, which is dependent on:
- Sediment/sea floor composition;
- Water depth;
- Duration of exposure;
- Distance of the animal to the source; and
- Ambient noise levels.

357. A series of underwater noise monitoring stations were installed by SEACAMS (University of Bangor) to sample the background noise levels in and around the MDZ over periods of between

15 and 30 days in 2016, 2017 and 2018. Four of these datasets from different time periods and locations have been analysed by Subacoustech (**Appendix 12.4, Appendix III**) to provide a range of noise levels to define a baseline over a daily (high-low) and fortnightly (springs-neaps) tidal cycle. All measurements analysed were taken with a 48 kHz sample rate and with contiguous 10-minute samples, except the June 2017 sample period which used a finer 1-minute sample period throughout.

358. The results of the background noise monitoring in these locations in and around the MDZ show a remarkable degree of consistency in all locations and time periods, and noise levels varying with position of the tide. There were occasional, rare outliers expected to be associated with passing vessel traffic. All locations show a range of noise levels of 89 dB to 107 dB SPLRMS re 1 µPa (as either 1-minute or 10-minute samples).

359. An overview of the noise levels sampled at each location is given in **Table 12-26** (excluding outliers).

Table 12-26 Summary of background noise levels in and around the MDZ

Period	Overall average noise level	Tide cycle: Springs		Tide cycle: Neaps	
		Max SPL_{RMS}	Min SPL_{RMS}	Max SPL_{RMS}	Min SPL_{RMS}
April 2017	98.3 dB SPL_{RMS}	103.0 dB	91.9 dB	99.7 dB	90.7 dB
June 2017	96.9 dB SPL_{RMS}	104.1 dB	89.1 dB	97.5 dB	89.7 dB
July 2017	98.9 dB SPL_{RMS}	106.4 dB	92.7 dB	100.2 dB	95.2 dB
July 2018	98.0 dB SPL_{RMS}	106.6 dB	89.9 dB	99.8 dB	92.6 dB

360. At MeyGen during August 2011 measurements of background underwater noise were recorded in the Inner Sound (Kongsberg, 2012). The Inner Sound is a turbulent location, with tides reaching speeds of 8-9 knots. Measurements were made from a drifting vessel, so that the differential flow of water across the hydrophone was minimised. **Table 12-27** summaries the background sea noise measurements undertaken in the Inner Sound (August 2011) and data are presented in sound pressure levels (SPL), sound exposure levels (SEL) and M-weighted SEL formats.

Table 12-27 Summary of the background sea noise measurements undertaken in the Inner Sound (August 2011)

Metric	Inner Sound
RMS SPL / SEL	106 - 139 dB re 1 µPa
M-Weighted SEL for low frequency cetaceans (minke whale)	102 – 131 dB re 1 µPa
M-Weighted SEL for mid frequency cetaceans (dolphin species)	106 - 139 dB re 1 µPa
M–Weighted SEL for high frequency cetaceans (harbour porpoise)	106 -139 dB re 1 µPa
M–Weighted SEL for pinnipeds in water (grey and harbour seal)	137 dB re 1 µPa

12.6.3.1.1. Underwater Noise Assessment

361. Underwater noise modelling has not currently been conducted for the MDZ, as the types of devices and how they could be installed has still to finalised. If required, underwater noise modelling will be undertaken pre-construction once the project design has been finalised. However, as a worst-case scenario, it has been assumed that the foundations of the tidal devices and hubs could be installed by drilling piles. Therefore, the assessment has been based on underwater noise modelling that has been conducted for drilling into a hard substrate at the

nearby Wylfa Newydd Development Area, drilling at the Perpetuus Tidal Energy Centre (PTEC) off the coast of the Isle of Wight and drilling at MeyGen in the Inner Sound of the Pentland Firth.

12.6.3.1.1.1. Drilling at Wylfa Newydd Development Area

362. The proposed Wylfa Newydd Development Area is located on the Wylfa peninsula, extending into the Irish Sea between the bays of Cemlyn and Cemaes, on the northern tip of the Isle of Anglesey off the North Wales coast. The distance to the Wylfa Newydd Development Area from the MDZ is 16.6 km.

363. Underwater noise modelling for the Wylfa Newydd Development Area was undertaken for rotary drilling, percussive drilling and concurrent drilling (HNP, 2018) and was updated to take into account the National Oceanographic and Atmospheric Association (NOAA) (National Marine and Fisheries Service (NMFS), 2018) thresholds and criteria (**Table 12-28**).

364. The NMFS (2018) guidance groups marine mammals into functional hearing groups and applies filters to the noise level to approximate the hearing response of the receptor:

- High Frequency (HF) Cetaceans, such as harbour porpoise;
- Mid Frequency (MF) Cetaceans, includes dolphin species, such as bottlenose dolphin, Risso's dolphin and common dolphin;
- Low Frequency (LF) Cetaceans, such as minke whale; and
- Phocid Pinnipeds Underwater (PW), such as grey and harbour seal.

365. For non-impulsive (i.e. continuous) noise, which is representative of drilling activity, NMFS (2018) presents cumulative weighted sound exposure criteria (SEL_{cum}) for both permanent threshold shift (PTS), where unrecoverable hearing damage may occur, and temporary threshold shift (TTS), where a short-term, recoverable effect on hearing sensitivity may occur in individual receptors. **Table 12-28** summarise the NMFS (2018) criteria for onset of risk of PTS and TTS for each of the key marine mammal hearing groups for non-impulsive noise.

Table 12-28 NMFS (2018) non-impulsive noise exposure criteria for PTS and TTS

Non-Impulsive noise	**PTS criteria**	**TTS criteria**
Hearing group	**Weighted SEL_{cum} (dB re 1 μPa²s)**	**Weighted SEL_{cum} (dB re 1 μPa²s)**
HF Cetaceans: harbour porpoise	173	153
MF Cetaceans: dolphin species	198	178
LF Cetaceans: minke whale	199	179
PW Pinnipeds: grey and harbour seal	201	181

366. Sound may be expressed in many different ways depending on the particular type of noise and the parameters of the noise that allow it to be evaluated in terms of a biological effect.

367. The attenuation of sound in the water as it propagates from the noise source must be considered in an assessment of potential impacts. As the measurement or receiver point moves away from the source, the sound pressure measured will decrease due to spreading. To standardise all source levels, regardless of where they are measured, they are referred back to a conceptual point 1m away from the point of origin of the noise. Consequently, source levels (**Table 12-29**) are presented with units of 'dB re 1 μPa @ 1 m'.

368. The sound pressure level (SPL) is normally used to characterise noise and vibration of a continuous nature such as drilling, boring, or background sea levels. To calculate the SPL, the variation in sound pressure is measured over a specific time period to determine the root mean square (RMS) level of the time varying acoustic pressure. The SPL_{RMS} therefore can be considered to be a measure of the average unweighted level of the sound over the measurement period.

369. The peak sound pressure level (SPL_{peak}) is the maximum level of sound. SPL_{peak} is often used to characterise sound transients from impulsive sources where there is a clear positive peak, such as impact piling or following the detonation of explosives. A peak SPL is calculated using the maximum variation of the pressure from positive to zero within the wave. This represents the maximum change in positive pressure (differential pressure from positive to zero) as the transient pressure wave propagates.

370. The Sound Exposure Level (SEL) sums the acoustic energy over a measurement period, and effectively takes account of both the SPL of the sound source and the duration for which the sound is present in the acoustic environment.

371. The cumulative sound exposure level (SEL_{cum}) takes into account the potential sound exposure level during the duration of the activity. For the SEL_{cum} modelling a worst-case static animal model was assumed for the Wylfa site. This assumes that the animal remains at a fixed distance from the noise source throughout, which in this case is a 24-hour period. This is assumed to be a very worst-case scenario, as it is more likely that animals exposed to high noise levels will move away from the noise source.

372. The source levels used in the underwater noise modelling for drilling at the Wylfa Newydd Development Area are summarised in **Table 12-29**. These source levels were derived using a combination of measurement data and extrapolations based on the differences in methodology, equipment and location.

Table 12-29 Summary of predicted source levels used for modelling drilling at Wylfa site

Noise source	**Predicted unweighted source level** (dB re 1 µPa (RMS) @ 1m)	**Predicted NMFS (2018) weighted source level** (dB re 1 µPa^{2}s @ 1m) (SEL)			
		LF Cetacean	**MF Cetacean**	**HF Cetacean**	**Pinniped**
Rotary drilling (242 kW)	161.2	153.3	116.9	110.1	139.6
Rotary drilling (570 kW)	164.9	157.0	120.6	113.8	143.3
Percussive drilling	185.3	181.4	146.5	139.9	167.5

373. Rotary drilling consists of two diameters and the rotating head is forced into the ground. Typical noise outputs from rotary drilling are characterised by a fairly continuous low pitch rumble with numerous higher levels of noise for short periods of time, as a result of the drill bit hitting inconsistencies in the rock.

374. Percussive drilling is different from rotary drilling as it adds a rapid hammer action to the rotating head. The noise is characterised by very rapid transient peaks associated with the hammer action of the drilling rig being used. Compared to rotary drilling, percussive drilling is a louder

process overall. Percussive drilling could be used over rotary drilling where harder substrate exists as the hammer action of the drill head would enable penetration into the harder material.

375. Measurements used in the modelling of rotary drilling were taken from measurements at close range to operations in Strangford Lough, Northern Ireland and the percussive drilling measurements that have been used were taken at the EMEC site off the coast of Eday, Orkney. The drills proposed for Wylfa varied in size compared to these measurements and as such a scaling factor was applied to the measurements in order to give a good estimate of the likely source levels.

376. The underwater noise modelling for the Wylfa Newydd Development Area was undertaken using the RAMSGeo software package which is designed to model any noise source where it is reasonable to assume it is a point source. RAMSGeo is a fully range dependent parabolic equation (PE) model that performs underwater acoustic transmission loss calculations. RAMSGeo is a purely theoretical model based solely around the physical acoustic processes that occur underwater.

377. The speed of sound in water is connected to temperature, and a representative sound speed of 1,489m/s was used in the modelling, based on a uniform temperature profile.

378. The seabed along the transects was assumed to be made up of predominately rock and hard substrate covered by a layer of sandy gravel. Similar to the predominately rock and hard substrate at the MDZ.

379. A location in 10m above ordinance datum water depth was used for the modelling at the Wylfa Newydd Development Area. All modelling for the Wylfa Newydd Development Area was conducted assuming a worst-case mean high water springs (MHWS) tide of 6.6m above LAT from the nearby Cemaes Bay. Three transects were modelled to illustrate the propagation of noise from the Wylfa site, with two of these extending out into the Irish Sea and deeper water, with 40-50m water depth in 5 km range of the noise modelling location. The results used in this assessment are based on the maximum potential impact ranges.

12.6.3.1.1.2. Drilling at PTEC

380. Underwater noise modelling of tidal devices and other associated noise at the Perpetuus Tidal Energy Centre off the coast of the Isle of Wight, England (Subacoustech, 2014) was undertaken prior to the NOAA (NMFS, 2016, 2018) thresholds and criteria. The noise metrics used were unweighted metrics (Parvin *et al*., 2007), the dB_{ht}(*Species*) (Nedwell *et al*., 2007) and M-Weighted SELs (Southall *et al*., 2007). The Source Level for the noise from percussive drilling operations was estimated to be 179.8 dB re 1 µPa@1 m (RMS) for installing a 4m diameter pile.

12.6.3.1.1.3. Drilling at MeyGen

381. Underwater noise modelling for the tidal turbine development in Inner Sound, Pentland Firth (Konsberg, 2012) was also undertaken prior to the NOAA (NMFS, 2016, 2018) thresholds and criteria. Drilling noise measurements indicate that limits of 144 dB re 1 µPa at 1m to 178 dB re 1 µPa at 1m may be considered representative for the activities at the Inner Sound site.

12.6.3.1.2. Potential Impacts from Underwater Noise During Drilling

12.6.3.1.2.1. Permanent Auditory Injury (PTS)

382. The maximum predicted impact ranges for the risk of PTS using the non-impulsive NMFS (2018) criteria for the proposed drilling operations at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-30**.

Table 12-30 Summary of the maximum predicted PTS impact ranges (and areas) for marine mammal species for drilling operations at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Rotary drilling [570 kW]	Percussive drilling	Two rotary drilling rigs	Two percussive drilling rigs
Range (and area*) for PTS in High Frequency Cetaceans (harbour porpoise) 173 dB re 1 µPa^{2}s Weighted SEL_{cum}	<1m (0.000003 km^2)	9m (0.00025 km^2)	<1m (0.000003 km^2)	10m (0.0003 km^2)
Range (and area*) for PTS in Mid Frequency Cetaceans (dolphin species) 198 dB re 1 µPa^{2}s Weighted SEL_{cum}	<1m (0.000003 km^2)	<1m (0.000314 km^2)	<1m (0.000003 km^2)	1m (0.000003 km^2)
Range (and area*) for PTS in Low Frequency Cetaceans (minke whale) 199 dB re 1 µPa^{2}s Weighted SEL_{cum}	4m (0.00005 km^2)	100m (0.03 km^2)	6m (0.0001 km^2)	210m (0.14 km^2)
Range (and area*) for PTS in Pinnipeds in water (grey and harbour seals) 201 dB re 1 µPa^{2}s Weighted SEL_{cum}	<1m (0.000003 km^2)	9m (0.00025 km^2)	<1m (0.000003 km^2)	10m (0.0003 km^2)

*based on area of a circle

383. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of PTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for two percussive drilling operations are presented in **Table 12-31**.

Table 12-31 Maximum number of individuals (and % of reference population) that could be at risk of permanent auditory injury (PTS) from cumulative exposure over a 24 hour period for two percussive drilling operations at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
PTS in harbour porpoise	0.00024 individuals (based on density estimate of 0.783/ km^2) (0.00000023% of the 104,695 reference population).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in bottlenose dolphin	0.00000006 individuals (based on density estimate of 0.02/ km^2) (0.000000015% of the reference population of 397 bottlenose dolphin)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in Risso's dolphin	0.00000009 individuals (based on density estimate of 0.031/ km^2) (0.000000001% of the reference population of 8,794 Risso's dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
PTS in common dolphin	0.00000066 individuals (based on density estimate of 0.22/ km^2) (0.000000001% of the reference population of 56,556 common dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in minke whale	0.0024 individuals (based on density estimate of 0.017/ km^2) (0.00001% of the reference population of 23,528 minke whale).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in grey seal	0.000049 individuals (based on density estimate of 0.155/ km^2) (0.0000008% of the reference population of 6,000 grey seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in harbour seal	0.00000015 individuals (based on density estimate of 0.0005/ km^2) (0.0000003% of the reference population of 50 harbour seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

384. The magnitude of the potential risk of PTS is assessed as **negligible / very low** for all species, with less than 0.001% of all relevant reference populations anticipated to be exposed to the permanent effect without any mitigation (**Table 12-31**).

385. Taking into account the high sensitivity of all marine mammal species to any permanent auditory injury (i.e. receptor has very limited capacity to recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species; **Table 12-31**), the impact significance (as defined in **Table 12-10**) for any permanent auditory injury in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure for two percussive drilling operations over 24 hours has been assessed as **minor (not significant)** (**Table 12-33**).

386. For PTEC, the source levels for the noise from percussive drilling operations was estimated to be 179.1 dB re 1 μPa@1 m (RMS) for the installation of 3m diameter piles. These levels are below the 240 and 220 dB re 1 μPa (SPL_{peak}) criteria for lethal effect and physical injury (Subacoustech, 2014). Therefore, no injury is anticipated.

387. Modelling undertaken for drilling at PTEC, based on the dB_{ht}(*Species*) criteria also indicates that for drilling noise the highest predicted source level was for harbour porpoise, for percussive drilling to install a 4m diameter pile, was 118.8 dB_{ht}(*Phocoena phocoena*)@1m. This is below 130 dB_{ht}(*Species*) perceived level used to indicate traumatic hearing damage (Subacoustech, 2014).

388. The modelling for PTEC, based on the M-weighted SEL Southall *et al*. (2007) thresholds is summarised in **Table 12-32**. The largest impact ranges are for the pinniped due to the more conservative criterion and shows a maximum range of 29m for installing the 3m pile through percussive drilling and 34m for a 4m pile. This means if a pinniped was positioned closer than 29m or 34m, respectively, from the drilling operation for 24 hours it would receive an exposure to sound that could be injurious using the Southall *et al*. (2007) criteria for non-pulses. However, the chance of a receptor staying this close to a noise source for such a long period of time is extremely unlikely (Subacoustech, 2014).

Table 12-32 Summary of the ranges out to which the injury criteria for non-pulses (Southall *et al*, 2007) is reached for percussive drilling noise over a 24 hour period modelled for PTEC (Subacoustech, 2014)

Percussive drilling	Range (m)			
	High Freq. Cetaceans (harbour porpoise) Range to 215 dB re 1 μPa²s	**Mid Freq. Cetaceans (dolphin species) Range to 215 dB re 1 μPa²s**	**Low Freq. Cetaceans (minke whale) Range to 215 dB re 1 μPa²s**	**Pinnipeds (in water) (grey and harbour seal) Range to 203 dB re 1 μPa²s**
1m diameter pile	2m	3m	4m	18m
2m diameter pile	3m	4m	5m	25m
3m diameter pile	4m	5m	6m	29m
4m diameter pile	6m	7m	8m	34m

389. For MeyGen, the source levels for drilling were considerably below the levels at which lethal injury to species of marine mammal might occur (240 dB re. 1 μPa). It was therefore considered unlikely that any marine animals would be killed as a consequence of the underwater noise from drilling activities at the Inner Sound development area.

390. The noise modelling for MeyGen also indicates that the peak source levels associated with drilling were also below the levels at which hearing damage from the underwater noise might occur (230 dB re. 1μPa and 224 dB re. 1μPa for the onset of Permanent Threshold Shift (PTS) and Temporary Threshold Shift (TTS) for cetaceans and 218 dB re. 1μPa and 212 dB re. 1μPa for the onset of PTS and TTS for pinnipeds). Even taking into account the more conservative criteria proposed by Lucke *et al*. (2009) for harbour porpoises (193.7 dB re 1 μPa) and those put forward by the US National Marine Fisheries Service (NMFS) (1995), whereby auditory injury may occur to pinnipeds and cetaceans following prolonged exposure to underwater sound at levels at or above 190 dB re. 1 μPa and 180 dB re. 1 μPa respectively, the source levels were sufficiently low such that the NMFS impact criteria were not exceeded (Kongsberg, 2012).

12.6.3.1.2.1.1. Mitigation

391. A MMMP for drilling activity would be prepared prior to construction, for example with the option of having MMOs on site during drilling activities to ensure marine mammals do not enter a predetermined mitigation zone, based on the maximum potential PTS impact range, e.g. 210m for minke whale. Although, to take into account the deeper water at the MDZ compared to the Wylfa site and the potential for increased noise propagation, the proposed mitigation zone for drilling activity would be a precautionary 500m.

12.6.3.1.2.1.2. Residual Impact

392. After the proposed mitigation, the residual impact would be negligible as marine mammals would be outwith the mitigation zone and potential area for any permanent auditory injury.

Table 12-33 Assessment of impact significance for any permanent auditory injury (PTS) in marine mammals from underwater noise during drilling to install tidal device and hub foundations at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
PTS during drilling to install tidal device and hub foundations	Harbour porpoise	High	Negligible / very low	Minor (not significant)	MMMP	Negligible
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Negligible
	Risso's dolphin		Negligible / very low	Minor (not significant)		Negligible
	Common dolphin		Negligible / very low	Minor (not significant)		Negligible
	Minke whale		Negligible / very low	Minor (not significant)		Negligible
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Negligible

12.6.3.1.2.2. Temporary Auditory Injury (TTS) and Disturbance

393. For all marine mammal species considered, a fleeing response is assumed to occur at the same noise levels as TTS and the potential impact is also described as 'likely disturbance'. The behavioural response of individuals to a noise stimulus will vary, and not all individuals will respond, or in the same way, however, for the purposes of this assessment, it is assumed that at the 'likely disturbance' range of TTS onset, 100% of the individuals exposed to the noise stimulus will respond and flee the area.

394. The maximum predicted impact ranges for TTS using the non-impulsive NMFS (2018) criteria for the proposed drilling operations at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-34**.

395. The maximum predicated impact range for minor behavioural response in harbour porpoise based on the unweighted Lucke *et al*. (2009) criteria of 145 dB re 1 μPa^{2}s (SEL_{ss}) for single strike and not cumulative exposure for two percussive drilling rigs was up to 530m a the Wylfa site. However, it should be noted that this criteria is for possible behavioural response and not all animals within this range would be predicted to be disturbed. Therefore, using the weighted TTS ranges for cumulative exposure based on the NOAA (NMFS, 2018) thresholds and criteria modelled for Wylfa also represents a good indication of the potential disturbance ranges.

Table 12-34 Summary of the maximum predicted TTS / fleeing response impact ranges (and areas) for marine mammal species for drilling operations at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Rotary drilling [570 kW]	Percussive drilling	Two rotary drilling rigs	Two percussive drilling rigs
Range (and area*) for TTS in High Frequency Cetaceans (harbour porpoise) 153 dB re 1 μPa^{2}s Weighted SEL_{cum}	6m (0.0001 km^2)	250m (0.2 km^2)	7m (0.00015 km^2)	320m (0.32 km^2)

Potential Impact	Rotary drilling [570 kW]	Percussive drilling	Two rotary drilling rigs	Two percussive drilling rigs
Range (and area*) for TTS in Mid Frequency Cetaceans (dolphin species) 178 dB re 1 µPa²s Weighted SEL_{cum}	<1m (0.000003 km²)	10m (0.0003 km²)	<1m (0.000003 km²)	20m (0.0013 km²)
Range (and area*) for TTS in Low Frequency Cetaceans (minke whale) 179 dB re 1 µPa²s Weighted SEL_{cum}	60m (0.01 km²)	1.5 km (7.07 km²)	90m (0.025 km²)	2.1 km (13.85 km²)
Range (and area*) for TTS in Pinnipeds in water (grey and harbour seals) 181 dB re 1 µPa²s Weighted SEL_{cum}	7m (0.00015 km²)	240m (0.18 km²)	8m (0.0002 km²)	320m (0.32 km²)

*based on area of a circle

396. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of TTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for two percussive drilling operations are presented in **Table 12-35**.

Table 12-35 Maximum number of individuals (and % of reference population) that could be at risk of temporary auditory injury (TTS) and fleeing response / disturbance from cumulative exposure over a 24 hour period for two percussive drilling operations at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
TTS / fleeing response in harbour porpoise	0.25 individuals (based on density estimate of 0.783/ km²) (0.00024% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in bottlenose dolphin	0.000026 individuals (based on density estimate of 0.02/ km²) (0.0000065% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in Risso's dolphin	0.00004 individuals (based on density estimate of 0.031/ km²) (0.0000005% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in common dolphin	0.0003 individuals (based on density estimate of 0.22/ km²) (0.0000005% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in minke whale	0.24 individuals (based on density estimate of 0.017/ km²) (0.001% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in grey seal	0.05 individuals (based on density estimate of 0.155/ km²) (0.0008% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
TTS / fleeing response in harbour seal	0.00016 individuals (based on density estimate of 0.0005/ km^2) (0.0003% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

397. The magnitude of the potential of TTS / fleeing response is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-35**).

398. Taking into account the medium sensitivity of all marine mammal species to any temporary auditory injury (i.e. receptor has limited capacity to recover from the anticipated impact; **Table 12-6**) and low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species; **Table 12-35**), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any temporary auditory injury or disturbance in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure for two percussive drilling operations over 24 hours has been assessed as **minor (not significant)** for TTS and **negligible** for disturbance (**Table 12-36**).

399. The modelling for PTEC, based on the dB_{ht}(*Species*) criteria that:

- For 90 and above, strong avoidance reaction by virtually all individuals; and
- For 75 and above, some avoidance reaction by the majority of individuals, but habituation or context may limit effect (e.g. in the presence of another biological imperative (such as migration to breeding or feeding grounds or avoiding a predator) individuals may not exhibit any behavioural reaction to the noise source).

400. The maximum range for 90 dB_{ht} is 76m for harbour porpoise, 22m for bottlenose dolphin, 42m for minke whale and 12m for grey and harbour seal and that the maximum range for 75 dB_{ht} is 780m for harbour porpoise, 180m for bottlenose dolphin, 280m for minke whale and 78m for grey and harbour seal (Subacoustech, 2014).

401. For Meygen, in a relatively noisy environment such as the Inner Sound where background noise levels are fairly high (in the range 106 – 139 dB re 1 μP), drilling noise propagates over only short distances (0.5 km) before it falls below background noise levels (Konsberg, 2012).

12.6.3.1.2.2.1. Mitigation

402. The proposed mitigation to reduce the risk of any PTS, for example, 500m mitigation zone and MMOs during drilling activity, will also reduce the risk of animals in the predicted impact area for TTS.

12.6.3.1.2.2.2. Residual Impact

403. After the proposed mitigation, the residual impact would be negligible for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, grey seal and harbour seal, as they would be outwith the mitigation zone (500m) and potential area for any temporary auditory injury. After

the proposed mitigation, the residual impact would be minor (not significant) for minke whale (**Table 12-36**).

Table 12-36 Assessment of impact significance for any temporary auditory injury (TTS) and disturbance in marine mammals from underwater noise during drilling to install tidal device and hub foundations within the MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
TTS during drilling to install tidal device and hub foundations	Harbour porpoise	Medium	Negligible / very low	Minor (not significant)	MMMP	Negligible
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Negligible
	Risso's dolphin		Negligible / very low	Minor (not significant)		Negligible
	Common dolphin		Negligible / very low	Minor (not significant)		Negligible
	Minke whale		Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Negligible
Disturbance during drilling to install tidal device and hub foundations	Harbour porpoise	Low	Negligible / very low	Negligible	No mitigation required.	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.3.1.2.3. Duration of Potential Disturbance during Drilling

404. As outlined in **Table 12-25**, the estimated total maximum duration of drilling for all tidal device and hubs foundation installation for 240MW array is up to 3,990 drilling days. Based on two deployment areas being developed at the same time, this could result in 1,995 days during the 10 year construction period (approximately 55%).

405. The 240MW array would not be installed all at once, but rather in phases with different deployment areas being developed at different times with different devices.

406. Drilling would not be continuous during the phases or construction period, but with gaps in drilling activity as vessels move to different positions within the sites, between different deployment areas being developed, plus any downtime for weather or any technical issues.

407. This assessment also does not take into account that not all foundations will require drilling (i.e. some will be GBS or anchored).

408. As a worst-case scenario it is assumed that marine mammals could be disturbed from areas for two percussive drilling rigs presented in **Table 12-34**, throughout the year for up to 5.5 years during the construction period. However, based on the maximum number of individuals that could potential be disturbed (**Table 12-35**), this is unlikely to result in significant disturbance (**Table 12-36**).

12.6.3.2. Underwater Noise During Other Construction Activities

409. In addition to the installation of the tidal device and hub foundations, other construction activities will include the cable installation and cable protection. Due to the hard substrate (bedrock) in the MDZ there will be very little, if any, seabed preparation.

410. As outlined in **Chapter 4, Project Description** and **Section 12.6.1.1.2**, due to the hard and rocky nature of the seabed, it is expected that the majority of the cables will be free laid with strategic protection (rock bags or concrete mattresses) at locations along the length. Where burial may be possible this will be done using jet trenching.

411. There are no clear indications that underwater noise caused by the installation of sub-sea cables poses a high risk of harming marine fauna (OSPAR, 2009). However, behavioural responses of marine mammals to dredging, an activity emitting comparatively higher underwater noise levels, are predicted to be similar to those during cable installation (OSPAR, 2009).

412. Based on reviews of published sources of underwater noise during dredging activity (e.g. Thomsen *et al*., 2006; CEDA, 2011; Theobald *et al*., 2011; WODA, 2013; Todd *et al*., 2014), sound levels that marine mammals may be exposed to during dredging activities are usually below auditory injury thresholds or PTS exposure criteria; however, TTS cannot be ruled out if marine mammals are exposed to noise for prolonged periods (Todd *et al*., 2014), although marine mammals remaining in close proximity to such activities for long periods of time is unlikely. Therefore, the potential risk of any auditory injury (permanent or temporary) in marine mammals as a result of dredging / cable installation activity is highly unlikely.

413. Underwater noise as a result of dredging activity/cable installation, has the potential to disturb marine mammals. Therefore, there is the potential for short, perhaps medium-term behavioural reactions and disturbance to marine mammals in the area during dredging / cable installation activity. Marine mammals may exhibit varying behavioural reactions intensities as a result of exposure to noise (Southall *et al*., 2007).

12.6.3.2.1. Underwater Noise Assessment

414. Underwater noise modelling has not been conducted for the MDZ, however, underwater noise modelling has been conducted for the nearby Wylfa Newydd Development Area, this included cutter-suction dredging on a hard substrate (HNP, 2018) and was updated to take into account the NOAA (NMFS, 2018) thresholds and criteria (**Table 12-28**).

415. The underwater noise modelling for cutter-suction dredging at Wylfa has been used as a precautionary worst-case scenario for the underwater noise that could be generated during the cable installation and placement of cable protection at the MDZ.

416. Cutter-suction dredging involves the use of a rotating cutter head to loosen rock in conjunction with a suction inlet that sucks up material onto the dredge vessel. Cutter-suction dredgers are often used in areas with harder substrata, such as rock. The dominant noise generated is characterised by short pulses that correspond with the cutter tool on the dredger, although noise from the vessel's engines can also be heard.

417. The source levels used in the underwater noise modelling of cutter-suction dredging for the Wylfa Newydd Development Area are summarised in **Table 12-37**. The source levels were derived using a combination of measurement data and extrapolations based on the differences in methodology, equipment and location. Further details of the underwater noise modelling conducted for the Wylfa Newydd Development Area is provided in **Section 12.6.3.1.1**.

Table 12-37 Summary of predicted source levels used for modelling cutter suction dredging at Wylfa

Noise source	**Predicted unweighted source level** (dB re 1 µPa (RMS) @ 1m)	**Predicted NMFS (2018) weighted source level** (dB re 1 µPa^{2}s @ 1m) (SEL)			
		LF Cetacean	**MF Cetacean**	**HF Cetacean**	**Pinniped**
Cutter-suction dredging	176.1	171.7	150.2	144.7	163.4

418. In addition to the underwater noise modelling for cutter-suction dredging in the Wylfa Newydd Development Area, reference is also made to underwater noise modelling for cable laying, rock placement and trenching in the Southern North Sea.

419. The underwater noise modelling in the Southern North Sea was undertaken for sites with water depths of 45-55m and sandy sediment. Although the sediments are different for the majority of the MDZ, this modelling provides an indication of potential underwater noise for areas where burial using jet trenching may be possible.

420. The underwater noise propagation modelling for the Southern North Sea sites was undertaken using a simple modelling approach for a number of offshore construction activities; using measured sound source data scaled to relevant parameters for the site. The unweighted source levels used were:

- Cable laying: estimated sound source of 171dB re 1µPs @1m (RMS)
  Based on eleven datasets from a pipe laying vessel measuring 300m in length; this is considered a worst-case noise source for cable laying operations.
- Rock placement: estimated sound source of 172dB re 1µPs @1m (RMS)
  Based on four datasets from rock placement vessel 'Rollingstone.'
- Trenching: estimated sound source of 172dB re 1µPs @1m (RMS)
  Based on three datasets of measurements from trenching vessels more than 100m in length.

12.6.3.2.2. Potential Impacts from Underwater Noise During Other Construction Activities

12.6.3.2.2.1. Permanent Auditory Injury (PTS)

421. The maximum predicted impact ranges for the risk of PTS using the non-impulsive NMFS (2018) criteria for the proposed cutter-suction dredging operations at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-38**.

Table 12-38 Summary of the maximum predicted PTS impact ranges (and areas) for marine mammal species for cutter-suction dredging operations at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Cutter-suction dredging
Range (and area*) for PTS in High Frequency Cetaceans (harbour porpoise) 173 dB re 1 µPa^2s Weighted SEL_{cum}	10m (0.0003 km^2)
Range (and area*) for PTS in Mid Frequency Cetaceans (dolphin species) 198 dB re 1 µPa^2s Weighted SEL_{cum}	1m (0.000003 km^2)
Range (and area*) for PTS in Low Frequency Cetaceans (minke whale) 199 dB re 1 µPa^2s Weighted SEL_{cum}	10m (0.0003 km^2)
Range (and area*) for PTS in Pinnipeds in water (grey and harbour seals) 201 dB re 1 µPa^2s Weighted SEL_{cum}	9m (0.00025 km^2)

*based on area of a circle

422. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of PTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for cutter-suction dredging operations / cable installation and protection at MDZ are presented in **Table 12-39**.

423. The magnitude of the potential risk of PTS is assessed as **negligible / very low** for all species, with less than 0.001% of all relevant reference populations anticipated to be exposed to the permanent effect without any mitigation (**Table 12-39**).

Table 12-39 Maximum number of individuals (and % of reference population) that could be at risk of permanent auditory injury (PTS) from cumulative exposure over a 24 hour period for cutter-suction dredging operations / cable installation and protection at MDZ, based on Wylfa modelling

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
PTS in harbour porpoise	0.00024 individuals (based on density estimate of 0.783/ km^2) (0.00000023% of the 104,695 reference population).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in bottlenose dolphin	0.00000006 individuals (based on density estimate of 0.02/ km^2) (0.000000015% of the reference population of 397 bottlenose dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in Risso's dolphin	0.00000009 individuals (based on density estimate of 0.031/ km^2) (0.000000001% of the reference population of 8,794 Risso's dolphin)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in common dolphin	0.00000066 individuals (based on density estimate of 0.22/ km^2) (0.000000001% of the reference population of 56,556 common dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in minke whale	0.000005 individuals (based on density estimate of 0.017/ km^2) (0.00000002% of the reference population of 23,528 minke whale).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in grey seal	0.00004 individuals (based on density estimate of 0.155/ km^2) (0.0000007% of the reference population of 6,000 grey seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in harbour seal	0.0000001 individuals (based on density estimate of 0.0005/ km^2) (0.0000002% of the reference population of 50 harbour seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

424. The maximum predicted impact ranges for the risk of PTS using the impulsive NMFS (2018) criteria for cable laying, rock placement and trenching in the Southern North Sea sites is presented in **Table 12-40**. In this assessment, a fleeing animal model has been used for SEL_{cum}. This more realistically assumes that the animal exposed to high noise levels will swim away from the noise source. For this a constant fleeing speed of 3.25m/s has been assumed for the low frequency (LF) cetaceans group (Blix and Folkow, 1995), based on data for minke whale, and for other receptors a constant rate of 1.5m/s has been assumed, which is a cruising speed for a harbour porpoise (Otani *et al.*, 2000). These are considered 'worst-case' as marine mammals are expected to be able to swim much faster under stress conditions. For example, Kastelein *et al*. (2018) recorded harbour porpoise swimming speeds of 1.97m/s during playbacks of pile driving sounds.

425. The modelling ranges smaller than 100m (cumulative) were not presented for the Southern North Sea sites and could therefore be a lot less than 100m. However, as a worst-case scenario, impact ranges of up to 100m have been assumed.

Table 12-40 Summary of the maximum predicted PTS impact ranges (and areas) for marine mammal species for cable laying, rock placement and trenching at Southern North Sea sites, based on NMFS (2018) weighted SEL_{cum} criteria for impulsive sounds

Potential Impact	Cable laying	Rock placement	Trenching
Range (and area*) for PTS in High Frequency Cetaceans (harbour porpoise) 155 dB re 1 µPa^{2}s Weighted SEL_{cum}	<100m (0.03 km^2)	<100m (0.03 km^2)	<100m (0.03 km^2)
Range (and area*) for PTS in Mid Frequency Cetaceans (dolphin species) 185 dB re 1 µPa^{2}s Weighted SEL_{cum}	<100m (0.03 km^2)	<100m (0.03 km^2)	<100m (0.03 km^2)
Range (and area*) for PTS in Low Frequency Cetaceans (minke whale) 183 dB re 1 µPa^{2}s Weighted SEL_{cum}	<100m (0.03 km^2)	<100m (0.03 km^2)	<100m (0.03 km^2)
Range (and area*) for PTS in Pinnipeds in water (grey and harbour seals) 185 dB re 1 µPa^{2}s Weighted SEL_{cum}	<100m (0.03 km^2)	<100m (0.03 km^2)	<100m (0.03 km^2)

*based on area of a circle

426. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of PTS from cumulative exposure, based on the density estimates for the MDZ and maximum area of impact for cable laying, rock placement and trenching are presented in **Table 12-41**.

427. The magnitude of the potential risk of PTS is again assessed as **negligible / very low** for all species, with less than 0.001% of all relevant reference populations anticipated to be exposed to the permanent effect without any mitigation (**Table 12-41**).

Table 12-41 Maximum number of individuals (and % of reference population) that could be at risk of permanent auditory injury (PTS) from cumulative exposure for cable laying, rock placement and trenching at MDZ, based on Southern North Sea modelling

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
PTS in harbour porpoise	0.024 individuals (based on density estimate of 0.783/ km^2) (0.000023% of the 104,695 reference population).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in bottlenose dolphin	0.0006 individuals (based on density estimate of 0.02/ km^2) (0.00015% of the reference population of 397 bottlenose dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in Risso's dolphin	0.0009 individuals (based on density estimate of 0.031/ km^2) (0.00001% of the reference population of 8,794 Risso's dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in common dolphin	0.0066 individuals (based on density estimate of 0.22/ km^2)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
	(0.00001% of the reference population of 56,556 common dolphin).	reference population anticipated to be exposed to effect).
PTS in minke whale	0.0005 individuals (based on density estimate of 0.017/ km^2) (0.000002% of the reference population of 23,528 minke whale).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in grey seal	0.005 individuals (based on density estimate of 0.155/ km^2) (0.00008% of the reference population of 6,000 grey seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in harbour seal	0.000015 individuals (based on density estimate of 0.0005/ km^2) (0.00003% of the reference population of 50 harbour seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

428. Taking into account the high sensitivity of all marine mammal species to any permanent auditory injury (i.e. receptor has very limited capacity to recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species; **Table 12-39** and **Table 12-41**), the impact significance (as defined in **Table 12-10**) for any permanent auditory injury in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure for cable installation and protection has been assessed as **minor (not significant)** (**Table 12-42**).

12.6.3.2.2.1.1. Mitigation

429. A MMMP for cable installation and cable protection activities would be prepared prior to construction, for example with the option of having MMOs on site to ensure marine mammals do not enter a predetermined mitigation zone, based on the potential PTS impact range, e.g. 100m. Although, the proposed mitigation zone could be a precautionary 500m.

12.6.3.2.2.1.2. Residual Impact

430. After the proposed mitigation, the residual impact would be negligible as marine mammals would be outwith the mitigation zone and potential area for any permanent auditory injury.

Table 12-42 Assessment of impact significance for any permanent auditory injury (PTS) in marine mammals from underwater noise during cable installation and protection at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
PTS during cable installation and cable protection	Harbour porpoise	High	Negligible / very low	Minor (not significant)	MMMP	Negligible
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Negligible
	Risso's dolphin		Negligible / very low	Minor (not significant)		Negligible
	Common dolphin		Negligible / very low	Minor (not significant)		Negligible
	Minke whale		Negligible / very low	Minor (not significant)		Negligible

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Negligible

12.6.3.2.2.2. Temporary Auditory Injury (TTS) and Disturbance

431. The maximum predicted impact ranges for TTS / disturbance using the non-impulsive NMFS (2018) criteria for the cutter-suction dredging operations at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-43**.

432. The maximum predicated impact range for minor behavioural response in harbour porpoise based on the unweighted Lucke *et al*. (2009) criteria of 145 dB re 1 μPa^{2}s (SEL_{ss}) for single strike and not cumulative exposure for cutter-suction dredging was up to 580m a the Wylfa site. However, as previously noted that this criteria is for possible behavioural response and not all animals within this range would be predicted to be disturbed. Therefore, using the weighted TTS ranges for cumulative exposure based on the NOAA (NMFS, 2018) thresholds and criteria modelled for Wylfa also represents a good indication of the potential disturbance ranges.

Table 12-43 Summary of the maximum predicted TTS / fleeing response impact ranges (and areas) for marine mammal species for cutter-suction dredging operations at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Cutter-suction dredging
Range (and area*) for TTS in High Frequency Cetaceans (harbour porpoise) 153 dB re 1 μPa^{2}s Weighted SEL_{cum}	260m (0.21 km^2)
Range (and area*) for TTS in Mid Frequency Cetaceans (dolphin species) 178 dB re 1 μPa^{2}s Weighted SEL_{cum}	10m (0.0003 km^2)
Range (and area*) for TTS in Low Frequency Cetaceans (minke whale) 179 dB re 1 μPa^{2}s Weighted SEL_{cum}	280m (0.25 km^2)
Range (and area*) for TTS in Pinnipeds in water (grey and harbour seals) 181 dB re 1 μPa^{2}s Weighted SEL_{cum}	70m (0.015 km^2)

*based on area of a circle

433. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of TTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for cutter-suction dredging operations / cable installation and protection are presented in **Table 12-44**.

434. The maximum predicted impact ranges for the risk of TTS / fleeing response using the non-impulsive NMFS (2018) criteria for cable laying, rock placement and trenching in the Southern North Sea sites was assessed as less than 100m (0.03 km^2) for all species, with the exception of rock placement for harbour porpoise which had a maximum predicted impact range of up to 990m (3.08 km^2).

435. The magnitude of the potential of TTS / fleeing response is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-44**).

Table 12-44 Maximum number of individuals (and % of reference population) that could be at risk of temporary auditory injury (TTS) and fleeing response / disturbance from cumulative exposure over a 24 hour period for cable installation and cable protection at MDZ, based on worst-case modelling for Wylfa and Southern North Sea sites

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
TTS / fleeing response in harbour porpoise[1]	2.4 individuals in 3.08 km^2 (based on density estimate of 0.783/ km^2) (0.002% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in bottlenose dolphin[2]	0.00006 individuals in 0.03 km^2 (based on density estimate of 0.02/ km^2) (0.00015% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in Risso's dolphin[2]	0.0009 individuals in 0.03 km^2 (based on density estimate of 0.031/ km^2) (0.00001% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in common dolphin[2]	0.007 individuals in 0.03 km^2 (based on density estimate of 0.22/ km^2) (0.000012% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in minke whale[3]	0.004 individuals in 0.25 km^2 (based on density estimate of 0.017/ km^2) (0.00017% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in grey seal[2]	0.005 individuals in 0.03 km^2 (based on density estimate of 0.155/ km^2) (0.00008% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in harbour seal[2]	0.000015 individuals in 0.03 km^2 (based on density estimate of 0.0005/ km^2) (0.00003% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

[1]based on 990m range modelled for rock placement at Southern North Sea Sites; [2]based on 100m range modelled for cable laying, rock placement and trenching at Southern North Sea; [3]based on cutter-suction dredging at Wylfa.

436. Taking into account the medium sensitivity of all marine mammal species to any temporary auditory injury (i.e. receptor has limited capacity to recover from the anticipated impact; **Table 12-6**) and low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any temporary auditory injury or disturbance in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure during cable installation and cable protection activities has been assessed as **minor (not significant)** for TTS and **negligible** for disturbance (**Table 12-45**).

12.6.3.2.2.2.1. Mitigation

437. The proposed mitigation to reduce the risk of any PTS, for example, 500m mitigation zone and MMOs, will also reduce the risk of animals in the predicted impact area for TTS.

12.6.3.2.2.2.2. Residual Impact

438. After the proposed mitigation, the residual impact would be negligible as marine mammals would be outwith the mitigation zone and potential area for any temporary auditory injury.

Table 12-45 Assessment of impact significance for any temporary auditory injury (TTS) and disturbance in marine mammals from underwater noise during cable installation and cable protection at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
TTS during cable installation and cable protection	Harbour porpoise	Medium	Negligible / very low	Minor (not significant)	MMMP	Minor (not significant)
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Negligible
	Risso's dolphin		Negligible / very low	Minor (not significant)		Negligible
	Common dolphin		Negligible / very low	Minor (not significant)		Negligible
	Minke whale		Negligible / very low	Minor (not significant)		Negligible
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Negligible
Disturbance during cable installation and cable protection	Harbour porpoise	Low	Negligible / very low	Negligible	No mitigation required.	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.3.2.2.3. Duration of Potential Disturbance during Other Construction Activities

439. As outlined in **Table 12-25**, the estimated total maximum duration of cable installation for 240MW array is up to 1,310 days, with an additional 108 days for cable protection with would begin up to one month after the start of the export cable laying. Based on two deployment areas being developed at the same time, this could result in 709 days during the 10 year construction period (approximately 19%).

440. The 240MW array would not be installed all at once, but rather in phases with different deployment areas being developed at different times with different devices.

441. Cable installation and cable protection activities would not be continuous during the phases or construction period, but with gaps as vessels move to different positions within the sites, between different deployment areas being developed, plus any downtime for weather or any technical issues.

442. As a worst-case scenario it is assumed that marine mammals could be disturbed from the areas presented in **Table 12-43**, for up to 1,418 days during the construction period. Or for two concurrent installation activities, twice the areas for half the duration (up 709 days). However, based on the maximum number of individuals that could potential be disturbed (**Table 12-44**), this is unlikely to result in significant disturbance (**Table 12-45**).

12.6.3.3. Underwater Noise and Disturbance from Construction Vessels

443. During the construction phase of the proposed scheme, there will be an increase in the number of vessels associated with construction activities. Vessel movements during construction will be within the MDZ and cable corridor area or travelling to and from the site. Installation support ports are likely to be Holyhead, Mostyn, Liverpool or Birkenhead; although ports further afield may be used.

444. As outlined in **Chapter 4, Project Description**, foundations would mainly be installed by a moored barge or Dynamic Positioning (DP) vessel. If a moored barge is used for installation, this will require one or two small support vessels to assist with positioning and anchor deployment. The TECs and supporting structures would then be installed separately using a DP vessel (likely to be the same as for the foundation installation) or a multi-cat vessel.

445. Cables will be installed using specialist cable installation vessel, barge or multi-cat, plus vessel or barge for installation of cable protection (rockbags / mattresses) and additional support vessel(s).

446. It is estimated that there could be up to 14 construction vessels in the MDZ and cable corridor at any one time, however, as a precautionary worst-case scenario the assessment has been based on 16 vessels, to allow for additional guard vessels.

447. Modelling by Heinänen and Skov (2015) indicates that the number of ships represents a relatively important factor determining the density of harbour porpoise in the CIS MU during summer, with markedly lower densities with increasing levels of traffic. A threshold level in terms of impact seems to be approximately 15,000 ships per year (approximately 50 vessels per day within a 5 km^2 area).

448. The number of construction vessels within the MDZ array area (35 km^2) and cable corridor area (4.75 km^2) would be well below this threshold with an estimated two vessels per 5 km^2. If all the vessels were within one development area (e.g. indicative smallest area of 1.85 km^2) and the cable corridor area (4.75 km^2) at any one time, there could be up to 11.5 vessels per 5 km^2.

449. **Chapter 15, Shipping and Navigation** provides a description of the existing marine traffic in and around the MDZ. Most vessel movements are inshore by small vessels such as recreational craft, workboats and small fishing vessels and the ferry route to the north of the MDZ.

450. Current traffic density of larger vessels carrying Automatic Identification System (AIS) is low within the MDZ during winter with less than four transits per month and up to 12 transits per month occurring in the northern most 200m of the MDZ as a result of the ferry route. In addition to ferries, five transits were made by four cruise ship vessels; within the two-week summer 2017 dataset. The cruise ships, while infrequent, are noted occupying a larger portion of the proposed MDZ.

451. Other vessel types which are active in and around the MDZ, include tugs and tows, survey vessels, RNLI vessels, construction and maintenance vessels and cable laying vessels. This vessel category is active across the entirety of the proposed MDZ. Holyhead is one of three main commercial fishing ports in Wales.

452. Holyhead Port is the third busiest port in Wales, providing a link to Ireland. There are approximately 8,500 vessel arrivals at Holyhead Harbour every year, equating to approximately 23 vessel movements (including commercial and recreational) per day.

453. Based on the precautionary worst-case scenario, including existing vessel movements in around the MDZ and cable corridor area, but taking into account that other vessels would be restricted from entering the immediate construction site (with a 500m safety zone around construction vessels and partially installed foundations), the number of vessels would be unlikely to exceed the Heinänen and Skov (2015) threshold level of 50 vessels per day in a 5 km^2 area. Therefore, there is unlikely to be the potential for significant disturbance to harbour porpoise as a result of the increased number of vessels during construction.

454. The construction vessels within the MDZ and cable corridor will be slow moving (or stationary) and most noise emitted is likely to be of a lower frequency, associated with large, slow moving vessels and the use of dynamic positioning systems.

455. Noise levels reported by Malme *et al*. (1989) and Richardson *et al*. (1995) for large surface vessels indicate that physiological damage to auditory sensitive marine mammals is unlikely. However, the levels could be sufficient to cause local disturbance to sensitive marine mammals in the immediate vicinity of the vessel, depending on ambient noise levels.

456. Underwater noise generated by vessels would not be sufficient to cause PTS and the potential for TTS is only likely if the animal remains in very close proximity to a vessel for a prolonged period of time, which is highly unlikely. Disturbance is therefore the only potential impact associated with the presence and underwater noise of vessels.

457. Thomsen *et al*. (2006) reviewed the effects of ship noise on harbour porpoise and seal species. As both species use lower frequency sound for communicating (with acute hearing capabilities at 2kHz) there is the potential for detection, avoidance and masking in both species. Thomsen *et al*. (2006) considered the detection thresholds for harbour porpoises (hearing threshold = 115dB rms re 1 µPa at 0.25 kHz; ambient noise = 91dB rms re 1 µPa at 2kHz) and concluded that ship noise around 0.25kHz could be detected at distances of 1 km; and ship noise around 2kHz could be detected at around 3 km. However, although the ship noise could be detected this does not mean that there would be an adverse reaction or disturbance.

12.6.3.3.1. Underwater Noise Assessment

458. Underwater noise modelling has not been conducted for the MDZ, however, underwater noise modelling has been conducted for vessels at the Wylfa Newydd Development Area (HNP, 2018) and was updated to take into account the NOAA (NMFS, 2018) thresholds and criteria (**Table 12-28**).

459. For the purposes of modelling, vessels were divided into two categories: medium sized and large sized. Medium sized vessels include support boats such as tugs and workboats, while the large sized vessels are equivalent of barges and the vessels used for foundations and cable installation.

460. The underwater noise propagation modelling was undertaken using a simple modelling approach for underwater noise associated with both medium and large sized vessels, using measured sound source data. The source levels used in the underwater noise modelling of large and medium vessels for the Wylfa Newydd Development Area are summarised in **Table 12-46**.

Table 12-46 Summary of predicted source levels used for modelling of vessels at Wylfa

Noise source	Predicted NMFS (2018) weighted source level (dB re 1 µPa^{2}s @ 1m) (SEL)			
	LF Cetacean	MF Cetacean	HF Cetacean	Pinniped
Large vessel movements	162.8	133.9	129.7	164.9
Medium vessel movements	155.0	126.1	121.9	157.1

461. It is important to highlight the transitory nature of underwater noise from passing vessels. Vessels used for foundations and cable installation would operate over an extended period in a defined area, so the cumulative noise exposure in a fixed position would be greater than the exposure from a vessel passing by.

462. For the modelling it was assumed that the vessels are travelling at an average speed of approximately 10 knots; the speed of the vessel would alter the sound level, with faster moving vessels generally creating more noise. The average vessel speed of 10 knots is based on the worst-case scenario, with vessels in and around the construction area typically moving at slower speeds.

463. Ambient underwater sound pressure levels were acquired between 2013 and 2014 to establish a baseline level of noise in the vicinity of Cemlyn Bay, Cemaes Bay and the Wylfa Newydd Development Area. This indicates that existing natural background noise levels for the area, with the mean underwater noise levels recorded between 111.4dB re 1µPa (SPL_{RMS}) and 120.9dB re 1µPa (SPL_{RMS}) (based on all transects measured). The noise levels generated from vessel movements would not be discernible above background noise after approximately 4.4 km for large vessels and 2.4 km for medium vessels (HNP, 2018).

12.6.3.3.2. Potential Impacts for Underwater Noise from Vessels

12.6.3.3.2.1. Permanent Auditory Injury (PTS)

464. The maximum predicted impact ranges for the risk of PTS using the non-impulsive NMFS (2018) criteria for large and medium vessels at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-47**.

Table 12-47 Summary of the maximum predicted PTS impact ranges (and areas) for marine mammal species for large and medium vessels at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Large vessels	Medium vessels
Range (and area*) for PTS in High Frequency Cetaceans (harbour porpoise) 173 dB re 1 µPa^{2}s Weighted SEL_{cum}	4m (0.00005 km^2)	<1m (0.000003 km^2)
Range (and area*) for PTS in Mid Frequency Cetaceans (dolphin species) 198 dB re 1 µPa^{2}s Weighted SEL_{cum}	<1m (0.000003 km^2)	<1m (0.000003 km^2)
Range (and area*) for PTS in Low Frequency Cetaceans (minke whale) 199 dB re 1 µPa^{2}s Weighted SEL_{cum}	10m (0.0003 km^2)	3m (0.00003 km^2)
Range (and area*) for PTS in Pinnipeds in water (grey and harbour seals) 201 dB re 1 µPa^{2}s Weighted SEL_{cum}	<1m (0.000003 km^2)	<1m (0.000003 km^2)

*based on area of a circle

465. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of PTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for large vessels at MDZ are presented in **Table 12-48**.

466. The magnitude of the potential risk of PTS is assessed as **negligible / very low** for all species, with less than 0.001% of all relevant reference populations anticipated to be exposed to the permanent effect (**Table 12-48**).

Table 12-48 Maximum number of individuals (and % of reference population) that could be at risk of permanent auditory injury (PTS) from cumulative exposure over a 24 hour period for large vessels at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)		Magnitude
	One large vessel	Up to 16 large vessels	
PTS in harbour porpoise	0.00004 individuals (based on density estimate of 0.783/ km^2) (0.0000004% of the 104,695 reference population).	0.0006 individuals (based on density estimate of 0.783/ km^2) (0.0000006% of the 104,695 reference population).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in bottlenose dolphin	0.00000006 individuals (based on density estimate of 0.02/ km^2) (0.000000015% of the reference population of 397 bottlenose dolphin).	0.000001 individuals (based on density estimate of 0.02/ km^2) (0.0000002% of the reference population of 397	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)		Magnitude
	One large vessel	Up to 16 large vessels	
PTS in Risso's dolphin	0.00000009 individuals (based on density estimate of 0.031/ km^2) (0.000000001% of the reference population of 8,794 Risso's dolphin)	0.000002 individuals (based on density estimate of 0.031/ km^2) (0.00000002% of the reference population of 8,794 Risso's dolphin)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in common dolphin	0.00000066 individuals (based on density estimate of 0.22/ km^2) (0.000000001% of the reference population of 56,556 common dolphin).	0.00001 individuals (based on density estimate of 0.22/ km^2) (0.00000002% of the reference population of 56,556 common dolphin).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in minke whale	0.000005 individuals (based on density estimate of 0.017/ km^2) (0.00000002% of the reference population of 23,528 minke whale).	0.00008 individuals (based on density estimate of 0.017/ km^2) (0.0000004% of the reference population of 23,528 minke whale).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in grey seal	0.0000005 individuals (based on density estimate of 0.155/ km^2) (0.000000008% of the reference population of 6,000 grey seal).	0.000007 individuals (based on density estimate of 0.155/ km^2) (0.0000001% of the reference population of 6,000 grey seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
PTS in harbour seal	0.0000000015 individuals (based on density estimate of 0.0005/ km^2) (0.000000003% of the reference population of 50 harbour seal).	0.00000002 individuals (based on density estimate of 0.0005/ km^2) (0.00000005% of the reference population of 50 harbour seal).	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

467. Taking into account the high sensitivity of all marine mammal species to any permanent auditory injury (i.e. receptor has very limited capacity to recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species), the impact significance (as defined in **Table 12-10**) for any permanent auditory injury in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure for vessels has been assessed as **minor (not significant)** (**Table 12-49**).

12.6.3.3.2.1.1. Mitigation

468. Given the small impact ranges (10m or less around each vessel) and very small number of marine mammals that could potentially be at risk of any permanent auditory injury (PTS) and the assessment of minor (not significant) impact, no mitigation measures are required or proposed.

12.6.3.3.2.1.2. Residual Impact

469. The residual impact would remain minor (not significant).

Table 12-49 Assessment of impact significance for any permanent auditory injury (PTS) in marine mammals from underwater noise from vessels at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
PTS from large vessels	Harbour porpoise	High	Negligible / very low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Risso's dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Minke whale		Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Minor (not significant)

12.6.3.3.2.2. Temporary Auditory Injury (TTS) and Disturbance

470. The maximum predicted impact ranges for TTS / disturbance using the non-impulsive NMFS (2018) criteria for large and medium vessels at the Wylfa Newydd Development Area, assuming a stationary animal remaining in the vicinity over a 24-hour period, are presented in **Table 12-50**.

Table 12-50 Summary of the maximum predicted TTS / fleeing response impact ranges (and areas) for marine mammal species for large and medium vessels at Wylfa, based on NMFS (2018) weighted SEL_{cum} criteria for non-impulsive sounds

Potential Impact	Large vessels	Medium vessels
Range (and area*) for TTS in High Frequency Cetaceans (harbour porpoise) 153 dB re 1 µPa^{2}s Weighted SEL_{cum}	140m (0.062 km^2)	30m (0.003 km^2)
Range (and area*) for TTS in Mid Frequency Cetaceans (dolphin species) 178 dB re 1 µPa^{2}s Weighted SEL_{cum}	3m (0.00003 km^2)	<1m (0.000003 km^2)
Range (and area*) for TTS in Low Frequency Cetaceans (minke whale) 179 dB re 1 µPa^{2}s Weighted SEL_{cum}	480m (0.72 km^2)	130m (0.053 km^2)
Range (and area*) for TTS in Pinnipeds in water (grey and harbour seals) 181 dB re 1 µPa^{2}s Weighted SEL_{cum}	40m (0.005 km^2)	9m (0.0003 km^2)

*based on area of a circle

471. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of TTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for large vessels are presented in **Table 12-51**.

472. The magnitude of the potential of TTS / fleeing response is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-51**).

Table 12-51 Maximum number of individuals (and % of reference population) that could be at risk of temporary auditory injury (TTS) and fleeing response / disturbance from cumulative exposure over a 24 hour period for large vessels at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)		Magnitude
	One large vessel	Up to 16 large vessels	
TTS / fleeing response in harbour porpoise	0.05 individuals (based on density estimate of 0.783/ km^2) (0.00005% of the 104,695 reference population).	0.78 individuals (based on density estimate of 0.783/ km^2) (0.0007% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in bottlenose dolphin	0.0000006 individuals (based on density estimate of 0.02/ km^2) (0.00000015% of the reference population of 397 bottlenose dolphin).	0.00001 individuals (based on density estimate of 0.02/ km^2) (0.000002% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in Risso's dolphin	0.0000009 individuals (based on density estimate of 0.031/ km^2) (0.00000001% of the reference population of 8,794 Risso's dolphin).	0.00001 individuals (based on density estimate of 0.031/ km^2) (0.0000002% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in common dolphin	0.000007 individuals (based on density estimate of 0.22/ km^2) (0.00000001% of the reference population of 56,556 common dolphin).	0.0001 individuals (based on density estimate of 0.22/ km^2) (0.0000002% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in minke whale	0.01 individuals (based on density estimate of 0.017/ km^2) (0.00004% of the reference population of 23,528 minke whale).	0.20 individuals (based on density estimate of 0.017/ km^2) (0.0008% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in grey seal	0.0008 individuals (based on density estimate of 0.155/ km^2) (0.00001% of the reference population of 6,000 grey seal).	0.01 individuals (based on density estimate of 0.155/ km^2) (0.0002% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in harbour seal	0.0000025 individuals (based on density estimate of 0.0005/ km^2) (0.000005% of the reference population of 50 harbour seal).	0.00004 individuals (based on density estimate of 0.0005/ km^2) (0.00008% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

473. Taking into account the medium sensitivity of all marine mammal species to any temporary auditory injury (i.e. receptor has limited capacity to recover from the anticipated impact; **Table 12-6**) and low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any temporary auditory injury or disturbance in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal from cumulative exposure from vessels has been assessed as **minor (not significant)** for TTS and **negligible** for disturbance (**Table 12-53**).

12.6.3.3.2.2.1. Mitigation

474. No mitigation measures are required or proposed.

12.6.3.3.2.2.2. Residual Impact

475. The residual impact would remain minor (not significant) for TTS and negligible for disturbance.

Table 12-52 Assessment of impact significance for any temporary auditory injury (TTS) and disturbance in marine mammals from underwater noise from vessels at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
TTS from vessels	Harbour porpoise	Medium	Negligible / very low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Risso's dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Minke whale		Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Minor (not significant)
Disturbance from vessels	Harbour porpoise	Low	Negligible / very low	Negligible	None required or proposed	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.3.3.2.3. Duration of Potential Disturbance from Construction Vessels

476. As outlined in **Table 12-24** and **Table 12-25**, there could be up to 16 vessels within the MDZ throughout the construction period. However, the activities and number of vessels required will vary throughout the construction period and it is unlikely that construction activities and the number of vessels on site would be continuous during the construction period.

477. As a worst-case scenario it is assumed that marine mammals could be disturbed from areas presented in **Table 12-50** throughout the construction period. However, based on the maximum number of individuals that could potential be disturbed (**Table 12-51**), this is unlikely to result in significant disturbance (**Table 12-52**).

12.6.3.4. Potential Barrier Effects from Underwater Noise During Construction

478. Underwater noise during construction could have the potential to create a barrier effect, preventing movement or migration of marine mammals between important feeding and / or breeding areas, or potentially increasing swimming distances if marine mammals avoid the site and go around it.

479. The worst-case scenario in relation to barrier effects as a result of underwater noise is based on the maximum spatial and temporal (i.e. longest duration) scenarios. This assumes the maximum potential disturbance and possible barrier effects during construction, in that there could be at any one time:

- Up to two drilling activities;
- Up to two cable installation activities;
- Up to two cable protection activities; and
- Up to 16 vessels on site.

480. The maximum duration for this potential combination of activities could be up to 709 days based on the maximum duration for two concurrent cable installation and protection activities, which could be underway at the same time as drilling activities for the foundation installation.

481. This assessment is precautionary as the vessels have been assessed separately, but in reality, these would be within the potential areas of disturbance for drilling, cable installation and cable protection activities.

482. The maximum predicted impact area for any potential barrier effects has been assessed based on the maximum predicted ranges for TTS / disturbance using the non-impulsive NMFS (2018) criteria for drilling, cable installation, cable protection and vessels (**Table 12-53**).

Table 12-53 Summary of the maximum predicted barrier effects for marine mammal species during construction, based on NMFS (2018) weighted SEL_{cum} criteria for TTS / fleeing response

Potential Impact	Two percussive drilling rigs	Cable installation and protection	Up to 16 large vessels	Maximum total area (% of MDZ and ECC area)
Area* for TTS / fleeing response in	0.32 km^2	6.58 km^2	0.99 km^2	7.89 km^2 (20%)

Potential Impact	Two percussive drilling rigs	Cable installation and protection	Up to 16 large vessels	Maximum total area (% of MDZ and ECC area)
High Frequency Cetaceans (harbour porpoise)				
Area* for TTS / fleeing response in Mid Frequency Cetaceans (dolphin species)	0.0013 km^2	0.12 km^2	0.0005 km^2	0.12 km^2 (0.3%)
Area* for TTS / fleeing response in Low Frequency Cetaceans (minke whale)	13.85 km^2	1 km^2	11.5 km^2	26.35 km^2 (66.3%)
Area* for TTS / fleeing response in Pinnipeds in water (grey and harbour seals)	0.32 km^2	0.12 km^2	0.08 km^2	0.52 km^2 (1.3%)

*based on area of a circle

483. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of potential barrier effects during construction has been based on the maximum areas for TTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for drilling, cable installation, cable protection and vessels (**Table 12-54**).

484. The magnitude of the potential of TTS / fleeing response is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-54**).

Table 12-54 Maximum number of individuals (and % of reference population) that could be impacted by any potential barrier effects from underwater noise during construction at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
TTS / fleeing response in harbour porpoise	6.2 individuals (based on density estimate of 0.783/ km^2) (0.006% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in	0.002 individuals (based on density estimate of 0.02/ km^2)	Temporary effect with negligible / very low magnitude (less than 1% of the reference

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
bottlenose dolphin	(0.0006% of the reference population of 397 bottlenose dolphin).	population anticipated to be exposed to effect).
TTS / fleeing response in Risso's dolphin	0.004 individuals (based on density estimate of 0.031/ km^2) (0.00004% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in common dolphin	0.03 individuals (based on density estimate of 0.22/ km^2) (0.00005% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in minke whale	0.45 individuals (based on density estimate of 0.017/ km^2) (0.0019% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in grey seal	0.08 individuals (based on density estimate of 0.155/ km^2) (0.001% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in harbour seal	0.0003 individuals (based on density estimate of 0.0005/ km^2) (0.0005% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

485. There is unlikely to be any potential barrier effects that could significantly affect the movements of marine mammals in or through the MDZ and ECC area during construction. As outlined in **Table 12-53**, the maximum area for disturbance and any barrier effects as a result of underwater noise during construction in relatively small in relation to the MDZ array and ECC area and when put into the context of the marine mammal MUs.

486. The potential for displacement from underwater noise is unlikely to result in any significant increase in energy expenditure that could be required by harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, grey seal and harbour seal to temporary avoid the maximum potential areas of disturbance in **Table 12-53**. Although the potential area of disturbance for minke whale is greater than for the other species, however, taking into account the movements and areas covered by minke whale, along with the number of whales that could be present in the area, again this is unlikely to result in any significant impacts (**Table 12-55**).

487. It is highly unlikely two drilling activities, two cable installation activities, two cable protection activities and 16 vessels on site, would occur all at the same time or for any prolonged period of time. Any disturbance during construction would be limited to the area around the activity within the MDZ array area and / or ECC, rather than across the entire site and as such there is unlikely to be any barrier effects as animals would be able to move around these discrete areas. For example, two drilling foundations installation events would be within two different deployment areas and likewise the related cable installation, protection and vessels would be associated with the two different deployment areas.

488. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact and the potential magnitude of

the effect (negligible/ very low for all species), the impact significance (based on the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any potential barrier effects as a result of underwater noise during construction for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal has been assessed as **negligible** (**Table 12-55**).

12.6.3.4.1. Mitigation

489. No mitigation measures are required or proposed.

12.6.3.4.2. Residual Impact

490. The residual impact would remain negligible.

Table 12-55 Assessment of impact significance for any temporary disturbance and barrier effects as a result of underwater noise during construction at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Barrier effects from underwater noise	Harbour porpoise	Low	Negligible / very low	Negligible	None required or proposed	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.3.5. Disturbance at Seal Haul-Out Sites

491. Hauled-out seals are sensitive to disturbance, particularly if they are in their breeding or moult periods. For grey seal, this is from August to December with a peak in October-November (see **Section 12.5.6.4**). There are no harbour seal haul-out sites in the vicinity of the MDZ (see **Plate 12-12**).

492. Studies on the distance of disturbance, on land or in the water, from hauled-out seals have found that the closer the disturbance, the more likely seals are to move into the water. For the grey seal, mothers responded by moving into the water more due to boat speed rather than as a result of the distance, although movement into the water was generally observed to occur at distances of between 20 and 70m, with no detectable disturbance at 150m (Wilson, 2014; Strong and Morris, 2010). However, grey seals have also been reported to move into the water when vessels are at a distance of approximately 200m to 300m (Wilson, 2014).

493. As outlined in **Table 12-20**, the closest grey seal pupping sites (based on Clarke *et al*., 2018) are located at Arw Cleft, 69m from the nearest point of the MDZ cable corridor area, however, no pups were recorded at this site during the 2017 survey. The rest of the grey seal sites are

beyond 200m from the nearest point of the MDZ cable area, with the closest located at Parliament House site 220m from the cable corridor area (**Figure 12-4, Volume II**).

494. There are no haul-out sites identified in the area for the proposed landfall at Abraham's Bosom on the west coast of Holy Island (**Figure 12-4, Volume II**).

495. Taking into account the distance of the proposed cable corridor area from the nearest grey seal pupping site (over 200m) and the proximity of current vessel movements to these sites (see **Chapter 15, Shipping and Navigation**), there is unlikely to be any increased disturbance at grey seal pupping sites as a result of vessels and any cable laying activity in the MDZ cable corridor area.

496. With the proximity of vessel movements, including current vessel routes to and from Holyhead Port, it is likely that seals hauled-out along these routes and in the area of the port would be habituated to the noise, movements and presence of vessels. Therefore, the sensitivity of grey seals at haul-out sites to disturbance from vessels during construction is likely to be negligible. As a very precautionary approach, it is proposed that sensitivity during the breeding season and annual moult could be slightly higher and has therefore been considered as low in this assessment for any activity in the cable corridor area at this time.

497. Vessel movements to the offshore project area would use direct routes and are unlikely to be close to the shore (i.e. within a few hundred metres) except when near the landfall site or port to avoid the risk of collision and grounding.

498. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible / very low), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any potential disturbance at grey seal haul-out sites has been assessed as **negligible** (**Table 12-56**).

12.6.3.5.1. Mitigation

499. No mitigation measures are required or proposed.

12.6.3.5.2. Residual Impact

500. The residual impact would remain negligible.

Table 12-56 Assessment of impact significance for any disturbance at grey seal haul-out sites during construction at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Disturbance haul-out sites	Grey seal	Low	Negligible / very low	Negligible	No mitigation is required or proposed	Negligible

12.6.3.6. Increased Collision Risk with Vessels

501. Marine mammals are able to detect and avoid vessels. However, vessel strikes are known to occur, possibly due to distraction whilst foraging and socially interacting, or due to the marine mammals' inquisitive nature (Wilson *et al*., 2007). Therefore, increased vessel movements, especially those out-with recognised vessel routes, can pose an increased risk of vessel collision to harbour porpoise, bottlenose dolphin, common dolphin, Risso's dolphin, minke whale, grey seal and harbour seal.

502. Studies have shown that larger vessels are more likely to cause the most severe or lethal injuries, with vessels over 80m in length causing the most damage to marine mammals (Laist *et al*., 2001). Vessels travelling at high speeds are considered to be more likely to collide with marine mammals, and those travelling at speeds below 10 knots would rarely cause any serious injury (Laist *et al*., 2001).

503. Harbour porpoise are small and highly mobile and given their responses to vessel noise (e.g. Thomsen *et al*., 2006; Evans *et al*.,1993; Polacheck and Thorpe, 1990), are expected to largely avoid vessel collisions. The Heinänen and Skov (2015) report indicates a negative relationship between the number of ships and the distribution of harbour porpoise in the Celtic and Irish Seas, suggesting that the species could exhibit avoidance behaviour which reduces the risk of strikes.

504. Of the 274 reported harbour porpoise strandings in 2015 (latest UK Cetacean Stranding's Investigation Programme (CSIP) Report currently available), 53 were investigated at post mortem (27 were conducted in England, 13 in Scotland and 13 in Wales). A cause of death was established in 51 examined individuals (approximately 96% of examined cases). Of these, four (8%) had died from physical trauma of unknown cause, which could have been vessel strikes (CSIP, 2015). Approximately 4% of all harbour porpoise post mortem examinations from the Baltic, North East Atlantic, Irish and North Seas (ASCOBANS area) are thought to have evidence of interaction with vessels (Evans *et al*., 2011). The UK CSIP report for 2015 reported a total of 18 minke whale stranding's; four of which were investigated at post mortem with none showing signs of vessel strike (CSIP, 2015). A total of 20 minke post mortems undertaken through the ASCOBANS area revealed that three (15%) show signs of physical trauma (Evans *et al*., 2011).

505. There is limited information on which to quantity the collision risk of marine mammals from the vessels likely to be used during construction. Although the risk of collision is likely to be low, as a precautionary worse-case scenario, the number of harbour porpoise, bottlenose dolphin, common dolphin, Risso's dolphin, minke whale, grey seal and harbour seal that could be at increased collision risk with vessels during construction of the proposed scheme has been assessed based on precautionary 5% to 10% of the number of individuals that could be present in the area potentially being at increased collision risk.

506. As outlined in **Section 12.6.3.3**, Holyhead Port is the third busiest port in Wales, and there are approximately 8,500 vessel arrivals at Holyhead Harbour every year, equating to approximately 23 vessel movements (including commercial and recreational) per day. Therefore, marine mammals in and around the MDZ would be custom to the presence and movements of vessels and would therefore be expected to detect and avoid vessels. Taking into account the potential

disturbance as a result of underwater noise (as assessed in **Section 12.6.3.3**) and that the construction vessels within the MDZ and cable corridor will be slow moving or stationary, harbour porpoise, bottlenose dolphin, common dolphin, Risso's dolphin, minke whale, grey seal and harbour seal are considered to have a low sensitivity to the risk of a vessel strike.

507. During the construction there will be an increase in vessel movements to and from the MDZ. However, where possible, vessels will follow established shipping routes to the relevant ports in order to minimise vessel traffic in the wider area.

508. As outlined in **Table 12-25**, the potential for increased collision risk with vessels during construction has been based on up to 16 vessels on site at any one time, with up to 16 vessel movements to and from the site per day. The maximum area of potential risk has been estimated based on construction vessels in indicative examples of the two potentially largest deployment areas (3 km^2 and 3 km^2); plus, vessels in ECC area (4.75 km^2). In addition, increased collision risk has also been estimated based on the potential vessel route area to and from Holyhead Harbour, based on a precautionary 250m buffer either side of the vessels.

Table 12-57 Estimated number of individuals (and % of reference population) that could be at increased collision risk with vessels during construction at MDZ

Species	Increased collision risk (5-10% of individuals in area at increased risk)			
	Two indicative deployment areas and cable corridor area (10.75 km^2).	**Vessel route to Holyhead Port (4.34 km^2)**	**Number of individuals (% of reference population) at potential increased risk in total area (15.09 km^2)**	**Magnitude**
Harbour porpoise	0.42-0.84 individuals (based on density estimate of 0.783/ km^2) (0.0004-0.008% of the 104,695 reference population).	0.17-0.34 individuals (based on density estimate of 0.783/ km^2) (0.0002-0.0003% of the 104,695 reference population).	0.59-1.18 individuals (0.0006-0.0011% of MU)	Potential permanent effect with negligible to low magnitude (0.01% or less of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.011-0.022 individuals (based on density estimate of 0.02/ km^2) (0.003-0.0054% of the reference population of 397 bottlenose dolphin)	0.0043-0.009 individuals (based on density estimate of 0.02/ km^2) (0.0011-0.0022% of the reference population of 397 bottlenose dolphin)	0.015-0.031 individuals (0.0038-0.0076% of MU)	Potential permanent effect with low magnitude (between 0.001% and 0.01% of the reference population anticipated to be exposed to effect).
Risso's dolphin	0.017-0.033 individuals (based on density estimate of 0.031/ km^2) (0.0002-0.0004% of the reference population of 8,794 Risso's dolphin).	0.007-0.014 individuals (based on density estimate of 0.031/ km^2) (0.0001-0.0002% of the reference population of 8,794 Risso's dolphin).	0.024-0.047 individuals (0.0003-0.0005% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).

Species	Increased collision risk (5-10% of individuals in area at increased risk)			
	Two indicative deployment areas and cable corridor area (10.75 km^2).	**Vessel route to Holyhead Port (4.34 km^2)**	**Number of individuals (% of reference population) at potential increased risk in total area (15.09 km^2)**	**Magnitude**
Common dolphin	0.12-0.24 individuals (based on density estimate of 0.22/ km^2) (0.0002-0.0004% of the reference population of 56,556 common dolphin).	0.05-0.096 individuals (based on density estimate of 0.22/ km^2) (0.0001-0.0002% of the reference population of 56,556 common dolphin).	0.17-0.336 individuals (0.0003-0.0006% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
Minke whale	0.009-0.02 individuals (based on density estimate of 0.017/ km^2) (0.00004-0.0001% of the reference population of 23,528 minke whale).	0.004-0.007 individuals (based on density estimate of 0.017/ km^2) (0.00002-0.00003% of the reference population of 23,528 minke whale).	0.013-0.027 individuals (0.0001-0.0001% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
Grey seal	0.083-0.17 individuals (based on density estimate of 0.155/ km^2) (0.0014-0.003% of the reference population of 6,000 grey seal).	0.034-0.067 individuals (based on density estimate of 0.155/ km^2) (0.0006-0.0011% of the reference population of 6,000 grey seal).	0.117-0.237 individuals (0.0019%-0.0039% of MU)	Potential permanent effect with negligible to low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Harbour seal	0.0003-0.0005 individuals (based on density estimate of 0.0005/ km^2) (0.0005-0.0011% of the reference population of 50 harbour seal).	0.0001-0.0002 individuals (based on density estimate of 0.0005/ km^2) (0.0002-0.0004% of the reference population of 50 harbour seal).	0.0004-0.0007 individuals (0.0008-0.0015% of MU)	Potential permanent effect with negligible to low magnitude (0.01% or less of the reference population anticipated to be exposed to effect).

509. Taking into account the low sensitivity of all marine mammal species to increased collision risk with vessels and the potential magnitude of the effect (negligible or low for all species), the impact significance for any permanent impact on harbour porpoise, bottlenose dolphin, grey seal and harbour seal has been assessed as **minor (not significant)** and **negligible** for Risso's dolphin, common dolphin and minke whale (**Table 12-58**).

12.6.3.6.1. Mitigation

510. Where possible, all vessel movements will be kept to the minimum number that is required to reduce any potential collision risk. Additionally, vessel operators will use good practice to reduce any risk of collisions with marine mammals. No further mitigation is proposed.

12.6.3.6.2. Residual Impact

511. The residual impact would remain negligible or minor (not significant).

Table 12-58 Assessment of impact significance for increased collision risk with vessels during construction at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Increased collision risk with vessels	Harbour porpoise	Low	Negligible to low	Negligible to minor (not significant)	No mitigation is required or proposed	Negligible to minor (not significant)
	Bottlenose dolphin		Low	Minor (not significant)		Minor (not significant)
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible to low	Negligible to minor (not significant)		Negligible to minor (not significant)

12.6.3.7. Potential Changes in Water Quality

512. As outlined in **Chapter 8, Marine Water and Sediment Quality**, the potential impacts on marine water quality are:

- Changes in marine water quality as a result of sediment re-suspension caused by seabed disturbance;
- Change in marine water quality as a result of mobilisation of contaminants adsorbed onto potentially re-suspended seabed sediments; and
- Impacts on marine water quality and sediment quality as a result of potential accidental discharge and spillage of oils, fuels and materials.

513. During the construction phase there is the potential for disturbance and re-suspension of sediments, either directly from the sea bed, or from sub-seabed cuttings, and for these re-suspended sediments to be dispersed through the water column as a plume. This has the potential to increase the suspended sediment concentrations and potentially increase turbidity around the MDZ.

514. Based on a 240MW capacity, the worst-case volume of cuttings for the entire site would amount to 117,780m^3. This is the total for all foundations and foundations will be installed sequentially. A single device requiring four drilled piles will produce 160m^3 of cuttings.

515. The maximum envisaged effect associated with sediment plumes arising from the foundation installation activities will cause a small increase in suspended sediment concentration (typically less than 1mg/l a short distance from the release point) over only a small geographical area (a few hundred metres). The effects will be temporary, with a return to very low background concentrations occurring rapidly upon cessation of installation activities (i.e. the effect is temporary only). Other than at the immediate release point, such a change would be

immeasurable and has been assessed as negligible in **Chapter 8, Marine Water and Sediment Quality**, with no mitigation required.

516. The free-laying of cables and the placement of cable protection would not cause plumes along the offshore sections of the cable corridor because the sea bed is characterised by bedrock or, where sparse sediment cover does exist, by sediments with a particle size that cannot be suspended in the water column.

517. In the nearshore, the bedrock is overlain by sand which has the potential to be disturbed. The assessment in **Chapter 8, Marine Water and Sediment Quality**, indicates that there could be a minor adverse (not significant) impact via increased suspended sediments in the area around the sandwave field and close to shore. However, the likely increase in suspended sediment concentration in areas with sand cover nearer to shore (including at the landfall) will remain within the natural variation that are governed by storm waves and surge effects. Any increase in suspended sediments would reduce rapidly with distance from the point of disturbance to a few mg/l over a small geographical area (within a few hundred metres, along the axis of tidal currents). Furthermore, these effects will be one-off and temporary in duration, with a return to the very low background concentrations occurring rapidly upon cessation of installation.

518. Marine mammals often inhabit turbid environments and cetaceans utilise sonar to sense the environment around them and there is little evidence that turbidity affects cetaceans directly (Todd *et al*., 2014). Pinnipeds are not known to produce sonar for prey detection purposes; however, it is likely that other senses are used instead of, or in combination with, vision. Studies have shown that vision is not essential to seal survival, or ability to forage (Todd *et al*., 2014).

519. Increased turbidity is unlikely to have a substantial direct impact on marine mammals that often inhabit naturally turbid or dark environments. This is likely because other senses are utilised, and vision is not relied upon solely. Therefore, harbour porpoise, bottlenose dolphin, common dolphin, Risso's dolphin, minke whale, grey seal and harbour seal have negligible sensitivity to increases in suspended sediments during construction.

520. The re-suspension of sediments during construction activities could also lead to the release of any contaminants that may be present within them. However, as outlined in **Chapter 8, Marine Water and Sediment Quality**, sediment contamination within the MDZ is low, due to the dynamic hydrological regime and generally low level of industrial activity in this region. The low proportion of fine sediments within the MDZ is another factor that indicates low sediment contamination levels. Therefore, the assessment determined a negligible impact on general water quality in the MDZ via release of contaminated sediments, as even though mobilisation of the relatively limited amount of sediments in the MDZ will occur via construction works, none of these sediments are known to have high levels of contaminants.

521. During construction there is the potential for changes in water quality as a result of accidental discharge and spillage of oils, fuels and materials. As outlined in **Chapter 8, Marine Water and Sediment Quality**, the liquid inventory for the Project indicates that there are large amounts of chemicals including oil, grease and hydraulic fluid that could be accidentally released/leaked from project components. Other sources of potential chemicals include drilling fluids from any drilled pin-piles. However, Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. An Marine Pollution Contingency Plan (MPCP) would be in

place and agreed with NRW in line with the Integrated Pollution Prevention and Control (IPPC) Directive such that any potential risk is minimised. Any permitted discharges would be small volumes, intermittent and dilute and disperse quickly.

522. If any such substances were accidentally released/leaked, quantities would likely be small due to relatively small amounts being present in individual devices. Due to the dynamic nature of the tidal and wave regime in and around the MDZ, lateral and vertical dispersion rates of any spilled substances would be expected to be high.

523. The assessment in **Chapter 8, Marine Water and Sediment Quality**, indicates the magnitude of this potential effect is considered to be low, as it is not anticipated to significantly affect local water quality and would also be temporary in nature (established controls would prevent further spillage/leakage once an event was detected).

524. Due to the limited chance of exposure of marine mammals to any contaminants released from the re-suspension of sediments or from the accidental discharge and spillage of oils, fuels and materials, the sensitivity of marine mammals has been classed as negligible.

525. Taking into account the negligible sensitivity of all marine mammal species to any changes in water quality and the potential magnitude of the effect (negligible or low), the impact significance for any temporary impact on harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale grey seal and harbour seal has been assessed as negligible (**Table 12-59**).

12.6.3.7.1. Mitigation

526. As outlined above and in **Chapter 8, Marine Water and Sediment Quality**, mitigation would include adherence to project-specific Environmental Management Plans (EMPs) and Marine Pollution Contingency Plans (MPCP). No further mitigation for marine mammals in proposed.

12.6.3.7.2. Residual Impact

527. The residual impact would remain negligible.

Table 12-59 Assessment of impact significance for any changes in water quality during construction at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Increased suspended sediments	Harbour porpoise	Negligible	Negligible	Negligible	EMP and MPCP	Negligible
	Bottlenose dolphin		Negligible	Negligible		Negligible
	Risso's dolphin		Negligible	Negligible		Negligible
	Common dolphin		Negligible	Negligible		Negligible
	Minke whale		Negligible	Negligible		Negligible
	Grey and harbour seal		Negligible	Negligible		Negligible

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Release of contaminants from re-suspension of sediments	Harbour porpoise	Negligible	Negligible	Negligible		Negligible
	Bottlenose dolphin		Negligible	Negligible		Negligible
	Risso's dolphin		Negligible	Negligible		Negligible
	Common dolphin		Negligible	Negligible		Negligible
	Minke whale		Negligible	Negligible		Negligible
	Grey and harbour seal		Negligible	Negligible		Negligible
Accidental discharge and spillage of oils, fuels and materials	Harbour porpoise	Negligible	Low	Negligible		Negligible
	Bottlenose dolphin		Low	Negligible		Negligible
	Risso's dolphin		Low	Negligible		Negligible
	Common dolphin		Low	Negligible		Negligible
	Minke whale		Low	Negligible		Negligible
	Grey and harbour seal		Low	Negligible		Negligible

12.6.3.8. Potential Changes in Prey Availability

528. Potential impacts on marine mammal prey species which could result in changes to prey availability include

- Underwater noise (that could lead to mortality, physical injury, auditory injury or behavioural responses);
- Physical disturbance and temporary loss of seabed habitat; and
- Increased suspended sediment concentrations and sediment re-deposition.

529. The diet of the harbour porpoise consists of a wide variety of prey species and varies geographically and seasonally, reflecting changes in available food resources. Harbour porpoise have relatively high daily energy demands and need to capture enough prey to meet its daily energy requirements. It has been estimated that, depending on the conditions, harbour porpoise can rely on stored energy (primarily blubber) for three to five days, depending on body condition (Kastelein *et al*., 1997). Harbour porpoise are therefore considered to have low to medium sensitivity to changes in prey resources.

530. Bottlenose and common dolphins are opportunistic feeders that have large foraging ranges (Santos *et al*., 2001; Reid *et al*., 2003; Sea Watch Foundation, 2012) and are therefore considered to have low sensitivity to changes in prey resources. Risso's dolphins have a more restricted diet than other dolphin species, feeding mostly on cephalopods (Santos *et al*., 1994) and are therefore are considered to have medium sensitivity to changes in prey resource.

531. Minke whale feed on a variety of prey species, but in some areas, they have been found to prey upon specific species at the population level. Therefore, minke whale are considered to have a medium sensitivity to changes in prey resource.

532. Grey and harbour seal feed on a variety of prey species. Both species are considered to be opportunistic feeders that are able to forage in other areas and have relatively large foraging ranges. Grey seal and harbour seal are therefore considered to have low sensitivity to changes in prey resources.

12.6.3.8.1. Prey Impacts from Underwater Noise during Construction

533. As outlined in the assessments for underwater noise on marine mammals, underwater noise modelling has not been conducted for the MDZ, however, underwater noise modelling has been conducted for the nearby Wylfa Newydd Development Area for drilling into a hard substrate, cutter-suction dredging as a proxy for cable installation and cable protection, and for large vessels (**Table 12-60**). The modelling was conducted based on the Popper *et al*. (2014) thresholds and criteria.

534. Fish responses to noise are in part related to the anatomy of their hearing mechanisms. The presence of a swim bladder enhances hearing sensitivity as the bladder acts as a pressure transducer, converting sound pressure to particle velocity. Those species where the swim bladder is near to or connected to the ear have increased hearing sensitivity. The hearing range of fish varies extensively amongst species, and it is not only related to anatomy, for example, cod and Atlantic salmon both have a swim bladder, but cod is sensitive to pressure at higher frequencies (Popper *et al*., 2014).

535. The categories for fish are based on the presence or absence of a swim bladder and the potential for the swim bladder to enhance hearing sensitivity:

- Fish with no swim bladder or other gas chamber, e.g. flatfish. These species generally only detect particle motion and are less sensitive to sound pressure.
- Fish with swim bladders in which hearing does not involve the swim bladder or other gas volume, e.g. Atlantic salmon. These species hear through particle motion.
- Fish in which hearing involves a swim bladder or other gas volume, e.g. herring and cod. These species detect sound pressure and particle velocity.

536. Fish with swim bladders involved in hearing are more sensitive to underwater noise and have the greatest potential impact ranges, therefore the results have been presented for these species as a worst-case scenario. The results are based on the stationary animal model (**Table 12-60**).

537. The number of marine mammals that could affected by any changes in prey availability has been assessed, based on the maximum potential area of impact (TTS) for prey species (based on two percussive drilling rigs, two cable installation activities, two cable protection activities (4 x cutter-suction dredging area) and up to 16 large vessels in **Table 12-61**.

538. It is important to note that the potential impact areas for marine mammals are greater than those predicted for their prey, therefore there would be no further impact as marine mammals would already be disturbed from the area of potential prey displacement.

Table 12-60 Summary of the maximum predicted impact ranges (and areas) for marine mammal prey species for drilling, cutter-suction dredging operations and large vessels at Wylfa, based on Popper *et al*. (2014) criteria for continuous sounds and predicted maximum total area of impact on prey species during construction

Potential Impact	Two percussive drilling rigs	Cutter-suction dredging / cable installation and protection	Large vessel	Maximum total area during construction*
Recoverable injury (fish with swim bladders involved in hearing) (48h) 170 dB re 1 µPa (SPL_{RMS})	13m (0.00053 km^2)	2m (0.000013 km^2)	<1m (0.000003 km^2)	0.00063 km^2
TTS (fish with swim bladders involved in hearing) (12h) 158 dB re 1 µPa (SPL_{RMS})	100m (0.031 km^2)	13m (0.00053 km^2)	4m (0.00005 km^2)	0.034 km^2

Areas based on area of a circle
*based on maximum area for two percussive drilling rigs, two cable installation activities, two cable protection activities and up to 16 large vessels.

539. The magnitude of the potential displacement due to changes in prey availability as a result of underwater noise during construction is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-61**).

Table 12-61 Maximum number of individuals (and % of reference population) that could be impacted by any changes of prey availability as a result of underwater noise during construction at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
Displacement of harbour porpoise due to changes in prey availability	0.3 individuals (based on density estimate of 0.783/ km^2) (0.00003% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of bottlenose dolphin due to changes in prey availability	0.0007 individuals (based on density estimate of 0.02/ km^2) (0.00017% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of Risso's dolphin due to changes in prey availability	0.001 individuals (based on density estimate of 0.031/ km^2) (0.000012% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of common dolphin due to	0.0075 individuals (based on density estimate of 0.22/ km^2)	Temporary effect with negligible / very low magnitude (less than 1% of the reference

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
changes in prey availability	(0.000013% of the reference population of 56,556 common dolphin).	population anticipated to be exposed to effect).
Displacement of minke whale due to changes in prey availability	0.001 individuals (based on density estimate of 0.017/ km^2) (0.000002% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of grey seal due to changes in prey availability	0.001 individuals (based on density estimate of 0.155/ km^2) (0.0001% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of harbour seal due to changes in prey availability	0.00002 individuals (based on density estimate of 0.0005/ km^2) (0.00003% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

540. The assessment in **Chapter 10 Fish and Shellfish Ecology**, has determined that the potential impacts of underwater noise on prey species would result a low magnitude of the effect, coupled with the medium sensitivity of the receptors, the impact significance was assessed as minor adverse on the receptors during construction. No mitigation measures were considered to be required.

12.6.3.8.2. Prey Impacts from Temporary Loss of Seabed Habitat during Construction

541. As outlined in **Chapter 10 Fish and Shellfish Ecology** and in **Table 12-25**, the worst-case scenario for temporary habitat loss during construction could be up to 0.42 km^2, based on area for post-lay burial of cables (27,259m^2), deployment of anchor blocks by barges during cable installation (100,240m^2), deployment of anchor blocks by barges during TEC device installation (248,000m^2) and deployment of anchor blocks by barges during hub installation(48,000m^2).

542. The magnitude of the potential displacement due to changes in prey availability as a result of temporary habitat loss during construction is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-63**).

Table 12-62 Maximum number of individuals (and % of reference population) that could be impacted by any changes of prey availability as a result of temporary habitat loss during construction at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
Displacement of harbour porpoise due to changes in prey availability	0.33 individuals (based on density estimate of 0.783/ km^2) (0.0003% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
Displacement of bottlenose dolphin due to changes in prey availability	0.0084 individuals (based on density estimate of 0.02/ km^2) (0.002% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of Risso's dolphin due to changes in prey availability	0.013 individuals (based on density estimate of 0.031/ km^2) (0.00015% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of common dolphin due to changes in prey availability	0.09 individuals (based on density estimate of 0.22/ km^2) (0.0002% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of minke whale due to changes in prey availability	0.007 individuals (based on density estimate of 0.017/ km^2) (0.00003% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of grey seal due to changes in prey availability	0.07 individuals (based on density estimate of 0.155/ km^2) (0.0011% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Displacement of harbour seal due to changes in prey availability	0.0002 individuals (based on density estimate of 0.0005/ km^2) (0.0004% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

543. The assessment in **Chapter 10, Fish and Shellfish Ecology**, has determined that the potential impacts of temporary habitat disturbance on prey species would result a low magnitude of the effect, coupled with the medium sensitivity of the receptors, the impact significance was assessed as minor adverse on the receptors during construction. No mitigation measures were considered to be required.

12.6.3.8.3. Prey Impacts from Increased Suspended Sediment and Sediment Re-Deposition during Construction

544. As outlined in **Section 12.6.3.7**, any changes in water quality will be negligible.

545. The assessment in **Chapter 10, Fish and Shellfish Ecology**, has also determined that the potential impacts of increased suspended sediment concentrations and sediment deposition on prey species would result a low magnitude of the effect, coupled with the medium sensitivity of the receptors, the impact significance was assessed as minor adverse on the receptors during construction. No mitigation measures were considered to be required.

12.6.3.8.4. Mitigation

546. No mitigation measures are required or proposed.

12.6.3.8.5. Residual Impact

547. The residual impact would remain negligible or minor (not significant).

Table 12-63 Assessment of impact significance for any displacement as a result of any changes to prey availability during construction at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Displacement due to underwater noise impact on prey species	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Negligible / very low	Negligible		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible
Displacement due to temporary habitat loss impact on prey species	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Negligible / very low	Negligible		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible
Displacement due to increased suspended sediment concentrations and sediment re-deposition impact on prey species	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Negligible / very low	Negligible		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible

12.6.4. Assessment of Potential Impacts During Operation, Maintenance and Repowering

12.6.4.1. Underwater Noise from Operational Tidal Devices

12.6.4.1.1. Review of Tidal Device Operational Noise

548. There is currently limited information on the underwater noise generated from operational tidal devices. However, some consented projects have taken turbine noise measurements from scaled down test devices and extrapolated these to provide a predicted source level. This has been reviewed and summarised below.

549. A study by Malinka *et al*. (2018) of the turbine at Strangford Lough found that metal flaps used to reduce the inflow of silt to the turbine produced regular low frequency (0.7 – 1.4 kHz) clanging noises with a source level of up to 185 - 198 dB re 1 μPa^2 which is approximately 96 dB above the auditory threshold for harbour porpoises at 1kHz (Kastelein *et al.,* 2002). Hydraulic pumps that rotate the turbine into the current were also a significant source of noise and caused false whistle detections at 13 kHz. However, the infrequent nature of this noise meant changes to average background noise levels were not deemed to be significant (Malinka *et al.,* 2018).

550. Measurements of noise emitted by a single tidal current turbine were taken in France using 19 drifting transects at varying distances (100 – 2,400m) from the device. Measured source level (SL) was between 118 to 152 dB re 1 μ Pa at 1m in third octave bands at frequencies between 40 and 8,192 Hz. This level was compared to a 19m boat travelling at 10 knots. The ‘acoustic footprint’ of the device was modelled and was found to extend to a radius of 1.5 km, however physiological injury to mammals, fish and invertebrates was considered to be improbable. Behavioural disturbance was estimated to occur within 1 km for harbour porpoises (Lossent *et al.,* 2018).

551. Schmitt *et al*. (2018) characterised the noise emitted by a subsea tidal kite and found broadband noise between 0.2 and 0.7 kHz. Sound levels varied in a repetitive cycle every seven seconds. Emitted noise levels decreased when rotations per minute were reduced from 500-700 rpm to 300-500 rpm from 105 dB re μPa to 95 re μPa. At higher kite speeds (4 to 5.5ms^{-1}) emitted noise levels were observed over a wider range of frequencies (0.05 to 0.9 kHz) (Schmitt *et al.,* 2018).

552. Robertson *et al.* (2018) conducted field trials in spring, summer and autumn 2017 where marine mammals were observed from land over a trial period of two weeks during each season. For half of each trial period, an underwater projector played recordings of tidal turbine sound at a broadband source level of 158 dB re μPa at 1m. Harbour seals did not show a significant behavioural response to the simulated turbine noise, however harbour seals would have needed to have been 10m away from the playback location to experience noise levels equivalent to previous studies that found a significant effect (Hastie *et al.,* 2017). During trial 1 (spring) calculated distances suggest harbour porpoise avoided the playback location by 300m, however in trial 2 (summer) this distance was reduced to 100m and during trial 3 (autumn) this distance disappeared and was reduced to zero. This change could suggest that the harbour porpoise became tolerant or habituated to the turbine noise (Robertson *et al.,* 2018).

553. Halvorsen *et al*. (2011) measured a turbine in the Bay of Fundy and found no change in ambient noise level greater than 200m away from the turbine and a source level of 162 dB re µm referred to 1m.

554. Vertical Axis turbines in Cobscook Bay, USA emit noise lower than the NOAA threshold for behavioural harassment by continuous noise (120 dB). Noise produced depended on if the turbine was freewheeling or generating, with a peak in source level of 110 dB at 105 Hz whilst freewheeling (Ocean Renewable Power Company, 2014).

555. The Brims Underwater Noise Assessment (Xodus, 2015) indicated that for 30 turbines, the extent of the potential disturbance for marine mammals for the operational tidal array was a radius of approximately 1 km from the centre of the array, and for 170 turbines, the extent of the potential disturbance could be 2 to 4 km. These noise ranges relate to device operation during full tidal flow, however during these periods the background noise will also be at its highest and this is not taken into consideration in the underwater noise modelling.

556. A study by Lossent *et al*. (2018) for a 16 m diameter, 0.5 MW, OpenHydro turbine, predicted a source noise level of 152 dB SPL_{RMS} and an acoustic spectrum with most energy in the 125 Hz ⅓ octave frequency band. Outside of this band, noise levels are a minimum of 10 dB lower. The low frequency for the OpenHydro turbine is below the peak hearing sensitivity of both pinniped and harbour porpoise, where at the greatest sensitivity range for these species the predicted octave-band source noise level from the device is at least 25 and 35 dB, respectively, below the low frequency peak. These noise levels are considerably below any which could potentially lead to PTS or TTS in the species. Moving away from the source location, this will fall quickly to the order of background noise levels and Lossent *et al*. (2018) estimated that this 'footprint' would be of the order of 1.0 to 1.5 km^2 around a turbine (**Appendix 12.4, Appendix III**).

557. For PTEC, a wide variety of tidal device designs and models were used to inform the Rochdale Envelope of the development site, these included:

- An axial flow device, mounted on a tripod base, secured with pin piles to the seabed. An example of this is the Deep Gen by Tidal Generation Ltd (TGL) Alstom, which has a rotor diameter of 18m.
- An axial flow device, mounted to the seabed using a monopile base; this has a higher rotational speed than the tripod base axial flow device with a tip speed of up to 41m/s. An example of this is the hyTyde by Voith Hydro, which has a rotor diameter of 16m.
- A bottom mounted pile with a surface piercing tower, for example, the SeaGen S by Marine Current Turbines, which is available with a rotor diameter of up to 24m.
- A ducted device, which is mounted to the seabed using a gravity base. Example of this includes the Tidal Turbine Generator by Clean Current Power Systems, which could have a rotor diameter of up to 10m and OpenHydro with a rotor diameter of up to 16m.
- Floating, surface piercing, multiple tidal energy convertors (TECs), such as the Scotrenewables Tidal Turbine or BlueTEC, which has two TECs, each with a rotor diameter of up to 24m for axial flow TECs or 10m diameter by 15m long vertical transverse axis TECs.

- Multiple buoyant, mid-water column, TECs attached to a single platform. An example of this is the PLAT-O by SME, which features two up to 12m diameter rotors.
- A bottom mounted, single platform with multiple TECs, for example the Deltastream by Tidal Energy Limited, which has 3 TECs mounted on a frame, each with rotor diameters of up to 20m.
- Transverse axis devices, for example the Turbine generator unit by Kepler, which uses a horizontal rotor which is up to 15m in diameter and 90m long.
- Multiple TECs on a single platform attached to a surface piercing structure attached to seabed, for example the Triton system by Tidal Stream Limited, which can be configured with up to 6 large rotors (up to 20m diameter) or 36 small TECs (around 4.5m in diameter).

558. Previous measurements of operational tidal devices undertaken by Subacoustech Environmental (Parvin *et al*., 2005; Parvin *et al*., 2008a) have shown that, using the information available, the level of noise introduced by the tidal devices was directly linked to the size of the tidal device, i.e. the larger the tidal device, the greater the sound it will produce while operational.

559. Therefore, in order to cover all of these designs in the underwater noise modelling for PTEC, three rotor diameters were chosen to give an idea of the sound from small, medium and large TECs; the three diameters were 10m, 15m and 20m. This covered all of the sizes of TEC considered for PTEC, as well as encompassing models where several smaller TECs are used on the same platform such as the device type with multiple small (approximately 4.5m) diameter rotors noted above; this range of TEC sizes also gives conservative estimates for any smaller size TECs.

560. Modelling of an operational tidal device with a rotor diameter of 24m was also been undertaken as a worst-case scenario in terms of rotor size and location for noise propagation at PTEC.

561. It should also be noted that this approximation was based on the data available at the time of the assessment (Subacoustech, 2014). The overall noise level does increase when a larger TEC is used but the frequency characteristics of the resulting noise will also differ due to mechanical differences in the TEC. For example, the tonal characteristics of noise from the gearbox of the tidal devices listed above, or the different types of rotors (open, ducted, transverse, etc.), may be different from the devices previously measured by Subacoustech Environmental (Subacoustech, 2014).

562. For the MeyGen project in the Pentland Firth, the predicted noise levels were up to 177 dB SPL_{RMS} for a 2.4MW turbine (extrapolated from a measured 0.3MW turbine in Strangford Lough, Northern Ireland). Most noise energy for this turbine was below 100Hz, although there were also significant peaks in the 1,500Hz and 5,000Hz bands (Kongsberg, 2012).

12.6.4.1.2. Potential Impacts for Underwater Noise from Operational Tidal Devices

563. The noise measurements and modelling for a range of different operational tidal devices, indicates that the noise levels would not be sufficient to result in any auditory injury. Therefore, the only potential impact is disturbance.

564. For PTEC, the source levels for the operational tidal device noise were estimated to be 155.8, 162.2, and 165.4 dB re 1 µPa@1 m (RMS) for the 10m, 15m, and 20m rotor diameters respectively, were below the 240 and 220 dB re 1 µPa (SPL_{peak}) criteria for lethal effect and physical injury (Subacoustech, 2014).

565. The modelling for MeyGen indicates that the source levels for operational noise from either the 1MW turbine or the 2.4MW turbine were below the levels at which lethal injury to species of marine mammal might occur (240 dB re. 1 µPa). It was therefore considered unlikely that any marine animals would be killed as a consequence of the underwater noise from any operational turbines in the Inner Sound development area (Konsberg, 2012).

566. The modelling for MeyGen also indicates that peak source levels associated with operational noise from either the 1MW or 2.4MW turbines were below the levels at which hearing damage from the underwater noise might occur (230 dB re. 1µPa and 224 dB re. 1µPa for the onset of PTS and TTS in cetaceans and 218 dB re. 1µPa and 212 dB re. 1µPa for the onset of PTS and TTS in pinnipeds). Even taking into account the more conservative criteria proposed by Lucke *et al*. (2009) for harbour porpoises (193.7 dB re 1 µPa) and NMFS (1995), whereby auditory injury may occur to pinnipeds and cetaceans following prolonged exposure to underwater sound at levels at or above 190 dB re. 1 µPa and 180 dB re. 1 µPa respectively, the source levels for operational noise for each turbine were sufficiently low such that the NMFS impact criteria were not exceeded (Konsberg, 2012).

Potential Disturbance from Underwater Noise of Operational Turbines

567. Although the noise levels are below injury levels, they may still be high enough to lead to avoidance behaviour. For example, Hastie *et al*. (2018) studied the reaction of harbour seals to simulated turbine noise in Kyle Rhea on the west coast of Scotland. The study found a reduction in seal abundance of between 11% and 41% at the source location. At up to 500m the reduction was just under 10%. The source used by Hastie *et al*. (2018) was based on a 1.2MW turbine design measured at SeaGen at Strangford Lough (**Appendix 12.4, Appendix III**).

568. The underwater noise modelling for PTEC predicted that the largest impact ranges were for harbour porpoise with a maximum range for 90 dB_{ht}(*Species*) level where a strong behavioural avoidance reaction is likely of 450m and a maximum range for 75 dB_{ht}(*Species*) of 7 km where some avoidance reaction could occur; both of these impact ranges are estimated for the largest 20m rotor diameter. The estimated impact ranges for the 24m diameter rotor were expected to extend the furthest for harbour porpoise, with a maximum 90 dB_{ht} impact range out to 610m and a 75 dB_{ht} impact range out to 9.1 km (Subacoustech, 2014; **Table 12-64**).

569. For PTEC, using the levels where the onset of TTS was found to occur in a harbour porpoise by Kastelein *et al*. (2012), a receptor would have to be present at a range of 800m around an operational 20m rotor diameter for an hour (Subacoustech, 2014).

Table 12-64 Summary of the modelled ranges for 90 and 75 dB_{ht}(*Species*) levels from an operational tidal device with a rotor diameter of 24m at PTEC

Potential Impact	90 dB_{ht}(*Species*) maximum range (m)	75 dB_{ht}(*Species*) maximum range (m)
Disturbance of harbour porpoise	610m	9,100m
Disturbance of bottlenose dolphin (dolphin species)	95m	2,200m
Disturbance of minke whale	400m	4,700m
Disturbance of grey and harbour seal	75m	2,000m

570. The underwater noise modelling for MeyGen indicates that odontocetes such as the harbour porpoise and dolphin species (bottlenose dolphin, Risso's dolphin and common dolphin) may not show signs of strong behavioural reactions from each 1MW turbine, while mysticetes such as minke whales, may respond out to 14m. Mild reactions in odontocetes and mysticetes may be seen at distances up to 140m and 364m, respectively, from the 1MW turbines. When exposed to 2.4MW turbine, odontocetes may exhibit strong behavioural reactions up to 14m from the turbines and mild behavioural reactions up to 350m and for mysticetes (minke whale) there could be mild behavioural reactions out to 1,736m (**Table 12-65**; Konsberg, 2012).

Table 12-65 Summary of the modelled ranges for 90 and 75 dB_{ht}(*Species*) levels from 2.4MW operational tidal devices at MeyGen

Potential Impact	90 dB_{ht}(*Species*) maximum range (m) (strong avoidance)	75 dB_{ht}(*Species*) maximum range (m) (mild avoidance)
Disturbance of harbour porpoise	14m	336m
Disturbance of bottlenose dolphin (dolphin species)	14m	336m
Disturbance of minke whale	42m	1,736m
Disturbance of grey and harbour seal	13m	28m

571. Based on the worst-case scenario for the PTEC noise modelling (**Table 12-64**), the number of marine mammals that could be disturbed from the underwater of operational turbines at MDZ has been estimated for one device based on the possible mild avoidance range for 75 dB_{ht}(*Species*) and 90 dB_{ht}(*Species*) (**Table 12-66**).

572. For full deployment the assessment has been based on the more realistic possible strong avoidance (90 dB_{ht}(*Species*) range from the worst-case scenario of the modelling for PTEC. The assessment for the full deployment has been based on arrays rather than individual tidal devices, as individual marine mammals would be more likely to be disturbed by the closest turbine they approach rather than all individual turbines within the array. As an indicative precautionary worst-case, the assessment has been based on up to 10 arrays, however the maximum number of arrays at the MDZ is likely to be eight. The areas are based on an area of a circle and assessment also assumes no overlap in disturbance areas between arrays / groups of turbines (**Table 12-66**).

Table 12-66 Maximum number of individuals (and % of reference population) that could be disturbed as a result of underwater from operational tidal devices at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)			Magnitude
	One device (possible mild avoidance (75dB$_{ht}$))	One device (possible strong avoidance (90dB$_{ht}$))	Full deployment* (possible strong avoidance (90dB$_{ht}$))	
Disturbance of harbour porpoise	204 individuals in 260.2 km^2 (based on density estimate of 0.783/ km^2) (0.195% of the 104,695 reference population).	0.92 individuals in 1.17 km^2 (based on density estimate of 0.783/ km^2) (0.0009% of the 104,695 reference population).	9.2 individuals in 11.7 km^2 (0.009% of MU)	Long term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of bottlenose dolphin	0.3 individuals in 15.21 km^2 (based on density estimate of 0.02/ km^2) (0.08% of the reference population of 397 bottlenose dolphin).	0.0006 individuals in 0.028 km^2 (based on density estimate of 0.02/ km^2) (0.00015% of the reference population of 397 bottlenose dolphin).	0.006 individuals in 0.28 km^2 (0.0015% for MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of Risso's dolphin	0.47 individuals in 15.21 km^2 (based on density estimate of 0.031/ km^2) (0.005% of the reference population of 8,794 Risso's dolphin).	0.0009 individuals in 0.028 km^2 (based on density estimate of 0.031/ km^2) (0.00001% of the reference population of 8,794 Risso's dolphin).	0.009 individuals in 0.28 km^2 (0.0001% for MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of common dolphin	3.35 individuals in 15.21 km^2 (based on density estimate of 0.22/ km^2) (0.006% of the reference population of 56,556 common dolphin).	0.006 individuals in 0.028 km^2 (based on density estimate of 0.22/ km^2) (0.00001% of the reference population of 56,556 common dolphin).	0.06 individuals in 0.28 km^2 (0.0001% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of minke whale	1.18 individuals in 69.4 km^2 (based on density estimate of 0.017/ km^2) (0.005% of the reference population of 23,528 minke whale).	0.0085 individuals (0.5 km^2; based on density estimate of 0.017/ km^2) (0.00004% of the reference population of 23,528 minke whale).	0.0085 individuals in 5 km^2 (0.0004% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of grey seal	1.95 individuals in 12.75 km^2 (based on density estimate of 0.155/ km^2) (0.003% of the reference population of 6,000 grey seal).	0.012 individuals in 0.018 km^2 (based on density estimate of 0.155/ km^2) (0.0002% of the reference population of 6,000 grey seal).	0.03 individuals in 0.18 km^2 (0.0005% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of harbour seal	0.006 individuals in 12.75 km^2 (based on density estimate of 0.0005/ km^2)	0.000009 individuals in 0.018 km^2 (based on density estimate of 0.0005/ km^2)	0.00009 individuals in 0.18 km^2 (0.00018% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of

Potential Impact	Maximum number of individuals and (% of reference population)			Magnitude
	One device (possible mild avoidance (75dBht))	One device (possible strong avoidance (90dBht))	Full deployment* (possible strong avoidance (90dBht))	
	(0.013% of the reference population of 50 harbour seal).	(0.000018% of the reference population of 50 harbour seal).		the reference population anticipated to be exposed to effect).

573. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect of very low / negligible for all marine mammal species, the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any possible long-term disturbance in harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal has been assessed as **negligible** (**Table 12-67**).

Table 12-67 Assessment of impact significance for long-term disturbance of marine mammals from underwater noise of operational tidal devices at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Disturbance from operational tidal devices	Harbour porpoise	Low	Very low / negligible	Negligible	No mitigation required or proposed.	Negligible
	Bottlenose dolphin		Very low / negligible	Negligible		Negligible
	Risso's dolphin		Very low / negligible	Negligible		Negligible
	Common dolphin		Very low / negligible	Negligible		Negligible
	Minke whale		Very low / negligible	Negligible		Negligible
	Grey and harbour seal		Very low / negligible	Negligible		Negligible

12.6.4.1.2.1.1. Mitigation

574. No mitigation measures are required or proposed.

12.6.4.1.2.1.2. Residual Impact

575. The residual impact would remain minor (not significant) for disturbance from operational turbines.

12.6.4.2. Underwater Noise and Disturbance from Maintenance and Repowering Activities

576. Although impacts will be less than during construction, as a worst-case scenario assessment has been based on assessment for construction in **Sections 12.6.3.1.2**, **12.6.3.2.2** and **12.6.3.4**.

577. As a precautionary worst-case scenario, the assessment is based on the assessment of potential barrier effects as a result of underwater noise during construction, which assumed

there could be up to two drilling activities; two cable installation activities; two cable protection activities; and up to 16 vessels on site (**Table 12-68**).

Table 12-68 Maximum number of individuals (and % of reference population) that could be disturbed by underwater noise during maintenance and repowering activities at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
Disturbance of harbour porpoise	1.7 individuals (based on density estimate of 0.783/ km^2) (0.0016% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of bottlenose dolphin	0.00006 individuals (based on density estimate of 0.02/ km^2) (0.000015% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of Risso's dolphin	0.00009 individuals (based on density estimate of 0.031/ km^2) (0.000001% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of common dolphin	0.0007 individuals (based on density estimate of 0.22/ km^2) (0.0000012% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of minke whale	0.45 individuals (based on density estimate of 0.017/ km^2) (0.0019% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of grey seal	0.07 individuals (based on density estimate of 0.155/ km^2) (0.0012% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of harbour seal	0.00023 individuals (based on density estimate of 0.0005/ km^2) (0.00046% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

578. It is highly unlikely two drilling activities, two cable installation activities, two cable protection activities and 16 vessels on site, would occur all at the same time or for any prolonged period of time. Any disturbance would be limited to the area around the activity within the MDZ array area and / or ECC.

579. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species), the impact significance (based on the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any disturbance as a result of underwater noise during maintenance and repowering activities for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal has been assessed as **negligible** (**Table 12-69**).

12.6.4.2.1. Mitigation

580. No mitigation measures are required or proposed.

12.6.4.2.2. Residual Impact

581. The residual impact would remain negligible.

Table 12-69 Assessment of impact significance for any temporary disturbance as a result of underwater noise during maintenance and repowering activities at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Disturbance during maintenance and repowering activities	Harbour porpoise	Low	Negligible / very low	Negligible	None required or proposed	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.4.3. Underwater Noise and Disturbance from Vessels

582. Although impacts from vessels during operation, maintenance and repowering will be less than during construction, as a worst-case scenario assessment has been based on assessment for construction in **Section 12.6.3.3**. However, it should be noted that vessels have also been included in the assessment for underwater noise and disturbance from maintenance and repowering activities in Section 12.6.4.2. Therefore, this is not an additional impact.

583. The maximum number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of TTS from cumulative exposure over a 24 hour period, based on the density estimates for the MDZ and maximum area of impact for large vessels are presented in **Table 12-75**.

584. The magnitude of the potential of TTS / fleeing response is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the temporary effect (**Table 12-75**).

Table 12-70 Maximum number of individuals (and % of reference population) that could be at risk of temporary auditory injury (TTS) and fleeing response / disturbance from cumulative exposure over a 24 hour period for large vessels at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)		Magnitude
	One large vessel	Up to 16 large vessels	
TTS / fleeing response in harbour porpoise	0.05 individuals (based on density estimate of 0.783/ km^2) (0.00005% of the 104,695 reference population).	0.78 individuals (based on density estimate of 0.783/ km^2) (0.0007% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)		Magnitude
	One large vessel	Up to 16 large vessels	
TTS / fleeing response in bottlenose dolphin	0.0000006 individuals (based on density estimate of 0.02/ km^2) (0.00000015% of the reference population of 397 bottlenose dolphin).	0.00001 individuals (based on density estimate of 0.02/ km^2) (0.000002% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in Risso's dolphin	0.0000009 individuals (based on density estimate of 0.031/ km^2) (0.00000001% of the reference population of 8,794 Risso's dolphin).	0.00001 individuals (based on density estimate of 0.031/ km^2) (0.0000002% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in common dolphin	0.000007 individuals (based on density estimate of 0.22/ km^2) (0.00000001% of the reference population of 56,556 common dolphin).	0.0001 individuals (based on density estimate of 0.22/ km^2) (0.0000002% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in minke whale	0.01 individuals (based on density estimate of 0.017/ km^2) (0.00004% of the reference population of 23,528 minke whale).	0.20 individuals (based on density estimate of 0.017/ km^2) (0.0008% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in grey seal	0.0008 individuals (based on density estimate of 0.155/ km^2) (0.00001% of the reference population of 6,000 grey seal).	0.01 individuals (based on density estimate of 0.155/ km^2) (0.0002% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
TTS / fleeing response in harbour seal	0.0000025 individuals (based on density estimate of 0.0005/ km^2) (0.000005% of the reference population of 50 harbour seal).	0.00004 individuals (based on density estimate of 0.0005/ km^2) (0.00008% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

585. Taking into account the medium sensitivity of all marine mammal species to any temporary auditory injury (i.e. receptor has limited capacity to recover from the anticipated impact; **Table 12-6**) and low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible/ very low for all species), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) has been assessed as **minor (not significant)** for TTS and **negligible** for disturbance for all species.

12.6.4.3.1.1.1. Mitigation

586. No mitigation measures are required or proposed.

12.6.4.3.1.1.2. Residual Impact

587. The residual impact would remain minor (not significant) for TTS and negligible for disturbance.

Table 12-71 Assessment of impact significance for any temporary auditory injury (TTS) and disturbance in marine mammals from underwater noise from vessels at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
TTS from vessels	Harbour porpoise	Medium	Negligible / very low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Risso's dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin		Negligible / very low	Minor (not significant)		Minor (not significant)
	Minke whale		Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal		Negligible / very low	Minor (not significant)		Minor (not significant)
Disturbance from vessels	Harbour porpoise	Low	Negligible / very low	Negligible	None required or proposed	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.4.4. Acoustic Deterrent Devices (ADDs)

588. Acoustic deterrent devices (ADDs) may be used as part of the mitigation plan to deter. The principle behind the use of ADDs is that they produce an aversive signal that causes a marine mammal to move away and out of the area of potential collision risk. ADDs have been used widely in an attempt to deter mammals from aquaculture facilities and fishing gear. ADDs have also been adopted as a method of deterring marine mammals to a 'safe distance' from the potential impact area surrounding a piling event to reduce the risk of permanent auditory injury (Gordon *et al*., 2007). ADDs are presently employed as a voluntary supplement to the 'standard' components of a Marine Mammal Management Plan (MMMP) in the UK and have been used recently for piling at UK offshore windfarm (OWF) sites including, for example, Beatrice, Dudgeon and Galloper. Several other UK wind farm projects are known to be including them in their current plans. In contrast, several European countries stipulate the use of ADDs as a standard component of their MMMPs for OWFs.

589. A potential disadvantage of ADDs is that their use introduces additional noise into the marine environment. ADDs rely on behavioural disturbance to work, although the risk of marine mammals receiving a dose of sound sufficient to cause auditory injury from ADDs is very low. The Joint Nature Conservation Committee (JNCC) guide to selection of ADDs (McGarry *et al*., 2018) modelled the potential for auditory injury from ADDs, assuming a swim speed of 2.5m/s

and 30 minutes of ADD activation. The results showed that the NOAA (NMFS, 2018) PTS threshold for all mammals was not exceeded beyond 100m for any of the devices modelled, with the exception of the SaveWave Orcasaver where PTS could potentially occur up to 130m from the device. It was therefore concluded that the risk of injury due to ADD deployment is low for all devices (McGarry *et al*., 2018).

590. There is a risk that using ADDs may add to the degree of disturbance and displacement, however their use in reducing the risk of collision with operational turbines, which theoretically has the potential to result in permanent or fatal injuries, is deemed beneficial compared to the relatively small area of their range over which disturbance and displacement could occur. For example, the Sea Mammal Research Unit (SMRU) assessed the potential for impact on marine mammals from the use of ADDs and concluded that although a disturbing noise source prior to piling could result in an approximately 6% increase in the duration of disturbing sound levels, the benefit of reducing the likelihood of injury was more important than the disturbance for a limited duration (Sparling *et al*., 2015).

591. The mitigation plan to reduce the collision risk with operational turbines will be developed in the pre-construction period, so that it is based upon best available information, methodologies, industry best practice, latest scientific understanding, current guidance and detailed project design. An outline mitigation and monitoring plan outlining the potential options and approach to be considered and developed in the pre-construction period has be included with the submission (**Document MOR/RHDHV/DOC/0072**). However, as the use ADDs could be considered as part of the mitigation, the potential disturbance effect of ADDs have been assessed.

592. In the JNCC guide to selection of ADDs in industry, which describes the commercially available ADDs and their applications (McGarry *et al*., 2018), the Offshore Renewables Joint Industry Project (ORJIP) review on the effectiveness of ADD for mitigation purposes (Herschel *et al*., 2013; 2014) and a review of the effectiveness of ADDs on minke whale (McGarry *et al*., 2017), the Lofitech device has been shown to be the most consistent and effective device for deterring seals, harbour porpoise and minke whale. The Lofitech device has successfully been used in a number of projects for a range of industries, including for aquaculture projects and the offshore wind industry. Therefore, this device has been used, as an example, in this assessment (**Table 12-73**). The Lofitech device has been designed to have a source noise level of 189 dB, with numerous field measurements confirming the device to have recorded source levels of 179 to 194 dB (Coram *et al*., 2014).

593. Studies have shown the Lofitech device to be effective for harbour porpoise with an immediate response on activation of the device (Brandt *et al*., 2012, 2013; McGarry *et al*., 2018). In tests of the effectiveness of the Lofitech device on harbour porpoise at a site in the German North Sea, the Lofitech device was active for four continuous hours and a total of ten trials were conducted (Brandt *et al*., 2013). During these trials, a significant decline in harbour porpoise detection was observed even at the furthest CPOD at 7.5 km from the source (Brandt *et al*., 2013). Harbour porpoise were not habituated to the device over trials of 4-6 months (Brandt *et al*., 2012). During construction at Dan Tysk offshore windfarm, the Lofitech device was found to deter porpoise between 12 km and up to 18 km (although not statistically significant for the latter). There was also no evidence of reduced effectiveness over the construction period (Dähne *et al*., 2017). The device noise source levels are below the sound level that could result

in PTS onset in harbour porpoise (202 dB re 1µPa SPL_{peak}) and TTS onset (196 dB re 1µPa SPL_{peak}) based on the NOAA criteria (NMFS, 2018).

594. There is no information available on the effectiveness of the Lofitech device on dolphin species. However, studies on the effectiveness of ADDs in captive dolphins has shown startle responses in bottlenose dolphins at ADD source levels of 135 dB re 1µPa RMS (Janik and Götz, 2015). It could therefore be assumed that the deterrence range of bottlenose dolphins from an ADD emitting a sound source level of 190 dB re 1 µPa with a high frequency could be more than 4 km (McGarry *et al*., 2017). However, it should be noted that this is untested.

595. There is very little information on the effect of ADDs on other dolphin species, such as Risso's dolphin and common dolphin. However, as they are classed as mid frequency cetaceans with a typical hearing range of 150 Hz to 160 Hz (NMFS, 2018), they would be expected to have a similar response as bottlenose dolphins. Acoustic devices are used to reduce by-catch of dolphin species. In trials of some of these devices there have been significantly lower detection rates of dolphin vocalisations. Leeny *et al*. (2007) also found during these trials, that continuous and responsive devices caused dolphins to leave the area rapidly.

596. The Lofitech device has been proven to effect minke whale behaviour up to 1 km from the source (McGarry *et al*., 2017). Within 15 minutes of ADD activation, minke whale were shown to travel to a minimum distance of 1.7 km from the ADD location, with a maximum deterrence range of 4.5 km detected. Mean swim speeds of minke whale away from the active device was found to be 15 km/h (± 4.7 km/h) (McGarry *et al*., 2017). This would be the equivalent of 4.2m/s. The device noise source levels are below the sound level that could result in PTS onset in minke whale (219 dB re 1µPa SPL_{peak}) and TTS onset (213 dB re 1µPa SPL_{peak}) based on the NMFS criteria (NMFS, 2018).

597. A number of different trials have shown that the Lofitech device is effective at deterring harbour and grey seals to a distance of 1 km from the device location (Brandt *et al*., 2012; 2013; Harris *et al*., 2014; Gordon *et al*., 2015). There was no habituation of harbour seals in field trials that occurred over several weeks (Gordon *et al*., 2015). However, some trials have indicated a potential deterrent range of 60m to 473m (Götz and Janik 2010; Gordon *et al*., 2015; McGarry *et al*., 2018). The noise source level from the Lofitech device (of a maximum 194 dB re 1 µPa) is also lower than the injury thresholds for seals in water, with PTS onset at 218 dB re 1µPa SPL_{peak} and TTS onset at 212 dB re 1µPa SPL_{peak} (NMFS, 2018).

598. In addition, as a precautionary approach, the assessment has also been based on a potential average disturbance range of approximately 1 km (3.14 km^2) for a range of ADD devices for all species, based on the JNCC guide for the selection and deployment of acoustic deterrent devices (McGarry *et al*., 2018) (**Table 12-72**).

Table 12-72 Summary of ADD deterrence distances from JNCC guide for the selection and deployment of acoustic deterrent devices (McGarry *et al*., 2018)

Species	ADD type	Range of deterrence distances[1]
Harbour porpoise	Lofitech Seal Scarer	300-1,200m
	Ace Aquatech: MMD (High Frequency)	50 – 6,000m

Species	ADD type	Range of deterrence distances[1]
	Ace Aquatech: Universal Scrammer	Likely avoidance between 200m and 1.2 km. Potential exclusion up to 6 km
	Terecos Ltd: DSMS-4	301m – 1.2 km
	Seamarco: Fauna Guard – FG Porpoise	Observed efficacy of at least 1,000m
	Airmar dB plus II	200m – 3,500 km
	Aquamark 848	Up to 1,500m
	DDD, DID from STM Products	1.2 to 3 km
Dolphin species	Ace Aquatech: MMMD (Mid Frequency)	50 – 1,000m
	Aquamark 848	Up to 1,500m
	DDD and DID (STM Products) [	1.2 to 3 km
Minke whale	Lofitech	1,000m
	Aquamark 848	Up to 1,500m
Seals	Lofitech Seal Scarer	60 to 473m. Behavioural response when seals within 1 km of sound source.
	Ace Aquatech MMMD (LOW)	50 – 1,000m
	Ace Aquatech: MMMD (High Frequency)	50 – 2,000m
	Ace Aquatech: Universal Scrammer	Between 200m and 1.4 km

[1]These ranges are likely to be influenced by factors such as local propagation characteristics, as well as animal's motivation, previous exposures to device and background noise levels.

599. As outlined in **Appendix 12.4** (**Volume III**), all of the devices are significantly above the background noise in the area and so this should not interfere with the audibility for the target species when in the vicinity of the devices. Although the source noise level, presented as an overall, broadband level, may be lower than the figure presented for a TEC, it must be taken into account that the acoustic frequency produced by each device is critical. For an ADD, to be effective in being audible to a marine mammal, it will operate at a much higher frequency, typically >5,000 Hz, than the dominant frequencies that will be produced by a TEC, and will thus remain clearly audible.

600. Commonly used ADDs, for example as supplied by Lofitech (Seal Scarer) and Ace Aquatech (e.g. the Marine Mammal Mitigation Device (MF) for pinnipeds and cetaceans) have a stated source level of 204 dB and 195 dB respectively, operating at frequency ranges of 10-20 kHz and 8-24 kHz. These are likely to be over 80 dB louder than the TECs at around 10m from the turbine (**Appendix 12.4, Volume III**).

601. As outlined in **Appendix 12.4** (**Volume III**), it is important to note, that audibility of the ADDs should not be considered the same as disturbance or displacement. The differences in the frequencies of typical ambient coastal noise, TEC machinery and an ADD means that there will be negligible interference with ADD audibility within the near vicinity of a TEC, where physical harm from a potential collision could occur. An ADD would therefore still be effective mitigation in the MDZ.

602. The requirements for ADD use has still to be determined during the development of the mitigation plan. Therefore, for this assessment a precautionary indicative example has been assumed in that there could be four ADDs at each of the arrays with a worst-case scenario of up to ten arrays, although a maximum of eight arrays are proposed for the MDZ (**Table 12-73**).

603. However, it is proposed that the ADDs would only be activated when marine mammals are in close proximity to the arrays and therefore not all 40 ADDs would ever be activated at the same time.

Table 12-73 Number of individuals (and % of reference population) that could be disturbed during ADD activation based on Lofitech device and average 1 km (3.24 km²) disturbance range

Potential Impact	One Lofitech device (maximum potential range)	Number of individuals and (% of reference population)			Magnitude
		One ADD (3.14 km²)	Full deployment for up to 10 ADDs (31.4 km²)	Full deployment for up to 40 ADDs (125.6 km²)	
Disturbance of harbour porpoise	Up to 7.5 km (177 km²) 139 individuals (0.13% of MU)	2.46 individuals (based on density estimate of 0.783/ km²) (0.002% of the 104,695 reference population).	24.6 individuals (based on density estimate of 0.783/ km²) (0.02% of the 104,695 reference population).	98 individuals (based on density estimate of 0.783/ km²) (0.09% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of bottlenose dolphin	Up to 4 km (50.3 km²) 1 individual (0.25% of MU)	0.06 individuals (based on density estimate of 0.02/ km²) (0.015% of the reference population of 397 bottlenose dolphin).	0.6 individuals (based on density estimate of 0.02/ km²) (0.15% of the reference population of 397 bottlenose dolphin).	2.5 individuals (based on density estimate of 0.02/ km²) (0.63% of the reference population of 397 bottlenose dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of Risso's dolphin	Up to 4 km (50.3 km²) 1.6 individual (0.02% of MU)	0.1 individuals (based on density estimate of 0.031/ km²) (0.001% of the reference population of 8,794 Risso's dolphin).	1 individual (based on density estimate of 0.031/ km²) (0.01% of the reference population of 8,794 Risso's dolphin).	4 individuals (based on density estimate of 0.031/ km²) (0.04% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of common dolphin	Up to 4 km (50.3 km²) 11 individual (0.02% of MU)	0.69 individuals (based on density estimate of 0.22/ km²) (0.001% of the reference population of 56,556 common dolphin).	7 individuals (based on density estimate of 0.22/ km²) (0.01% of the reference population of 56,556 common dolphin).	28 individuals (based on density estimate of 0.22/ km²) (0.05% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of minke whale	Up to 4.5 km (64 km²) 1 individual (0.004 of MU)	0.05 individuals (based on density estimate of 0.017/ km²)	0.05 individuals (based on density estimate of 0.017/ km²)	2 individuals (based on density estimate of 0.017/ km²)	Temporary effect with negligible / very low magnitude

Potential Impact	One Lofitech device (maximum potential range)	Number of individuals and (% of reference population) One ADD (3.14 km^2)	Full deployment for up to 10 ADDs (31.4 km^2)	Full deployment for up to 40 ADDs (125.6 km^2)	Magnitude
		(0.0002% of the reference population of 23,528 minke whale).	(0.0002% of the reference population of 23,528 minke whale).	(0.01% of the reference population of 23,528 minke whale).	(less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of grey seal	Up to 1 km (3.14 km^2) 0.49 individuals (0.008% of MU)	0.49 individuals (based on density estimate of 0.155/ km^2) (0.008% of the reference population of 6,000 grey seal).	5 individuals (based on density estimate of 0.155/ km^2) (0.08% of the reference population of 6,000 grey seal).	19.5 individuals (based on density estimate of 0.155/ km^2) (0.32% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of harbour seal	Up to 1 km (3.14 km^2) 0.002 individuals (0.004% of MU)	0.002 individuals (based on density estimate of 0.0005/ km^2) (0.004% of the reference population of 50 harbour seal).	0.02 individuals (based on density estimate of 0.0005/ km^2) (0.04% of the reference population of 50 harbour seal).	0.06 individuals (based on density estimate of 0.0005/ km^2) (0.13% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

604. The duration of the ADD activation has also still to be determined, therefore as a precautionary approach the assessment has been based on possible 10 and 20 minute activation and the distance marine mammals could be disturbed based on them swimming away for the ADD during this activation time (**Table 12-74**). For minke whale the average swimming speed of 3.25m/s has been used (Blix and Folkow, 1995) and for all other species an average marine mammal swimming speed of 1.5m/s (Otani *et al*., 2000) has been assumed.

Table 12-74 Number of individuals (and % of reference population) that could be disturbed during ADD activation for 10 and 20 minutes

Potential Impact	Number of individuals and (% of reference population)		Magnitude
	10 minute ADD activation	20 minute ADD activation	
Disturbance of harbour porpoise (1.5m/s swim speed)	2 individuals (2.54 km^2; based on density estimate of 0.783/ km^2) (0.002% of the 104,695 reference population).	8 individuals (10.18 km^2; based on density estimate of 0.783/ km^2) (0.008% of the 104,695 reference population).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of bottlenose dolphin	0.05 individuals (2.54 km^2; based on density estimate of 0.02/ km^2) (0.01% of the reference	0.2 individuals (10.18 km^2; based on density estimate of 0.02/ km^2) (0.05% of the reference	Temporary effect with negligible / very low magnitude (less than 1% of the reference population

Potential Impact	Number of individuals and (% of reference population)		Magnitude
	10 minute ADD activation	20 minute ADD activation	
(1.5m/s swim speed)	population of 397 bottlenose dolphin).	population of 397 bottlenose dolphin).	anticipated to be exposed to effect).
Disturbance of Risso's dolphin (1.5m/s swim speed)	0.08 individuals (2.54 km^2; based on density estimate of 0.031/ km^2) (0.001% of the reference population of 8,794 Risso's dolphin).	0.32 individuals (10.18 km^2; based on density estimate of 0.031/ km^2) (0.004% of the reference population of 8,794 Risso's dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of common dolphin (1.5m/s swim speed)	0.56 individuals (2.54 km^2; based on density estimate of 0.22/ km^2) (0.001% of the reference population of 56,556 common dolphin).	2.24 individuals (10.18 km^2; based on density estimate of 0.22/ km^2) (0.003% of the reference population of 56,556 common dolphin).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of minke whale (3.25m/s swim speed)	0.2 individuals (11.95 km^2; based on density estimate of 0.017/ km^2) (0.001% of the reference population of 23,528 minke whale).	0.81 individuals (47.78 km^2; based on density estimate of 0.017/ km^2) (0.001% of the reference population of 23,528 minke whale).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of grey seal (1.5m/s swim speed)	0.39 individuals (2.54 km^2; based on density estimate of 0.155/ km^2) (0.01% of the reference population of 6,000 grey seal).	1.6 individuals (10.18 km^2; based on density estimate of 0.155/ km^2) (0.03% of the reference population of 6,000 grey seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).
Disturbance of harbour seal (1.5m/s swim speed)	0.001 individuals (2.54 km^2; based on density estimate of 0.0005/ km^2) (0.003% of the reference population of 50 harbour seal).	0.005 individuals (10.18 km^2; based on density estimate of 0.0005/ km^2) (0.01% of the reference population of 50 harbour seal).	Temporary effect with negligible / very low magnitude (less than 1% of the reference population anticipated to be exposed to effect).

605. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect (negligible / very low for all species), the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for disturbance as a result of ADDs has been assessed as **negligible** (**Table 12-75**).

Table 12-75 Assessment of impact significance for possible disturbance of marine mammals from underwater noise during ADD activation at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Disturbance during ADD activation	Harbour porpoise	Low	Negligible / very low	Negligible	No mitigation required.	Negligible
	Bottlenose dolphin		Negligible / very low	Negligible		Negligible
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible / very low	Negligible		Negligible

12.6.4.4.1. Mitigation

606. No further mitigation measures are required or proposed.

12.6.4.4.2. Residual Impact

607. The residual impact would remain negligible.

12.6.4.5. Collision Risk with Tidal Devices

608. There is considerable uncertainty regarding the collision risk of marine mammals with all tidal turbine types. The moving rotors of tidal energy devices pose a potential collision risk for marine mammals. However, there is currently limited understanding and empirical data relating interactions between marine mammals with tidal devices and there have been no recorded incidents at any operational tidal arrays, including the following projects in the UK:

- Several years of operation of the SeaGen tidal turbine (Strangford Lough) 1.4MW tidal device;
- Ongoing monitoring of multiple deployments of single tidal devices in the Falls of Warness (EMEC, Orkney) test site since 2007; and
- Ongoing monitoring of Phase 1a (6MW) of the MeyGen (Caithness) array, the full phase 1 (86MW) of which is now consented.

609. SeaGen as it was deployed in 2008 and there were no marine mammal collision incidents reported during its operational monitoring. Although the SeaGen device has now been removed, data from its monitoring programmes are still being analysed. The European Marine Energy Centre (EMEC) at Orkney has tested many different devices and no incidents involving collisions with marine mammals have been recorded (SLR, 2015).

610. There is an absence of data to determine the ability of animals to avoid coming into contact with devices, either through close-range evasion, where animals take last minute evasive action, or through avoidance, which may operate at a wider scale with animals avoiding the area the devices are located in (Sparling and Smith, 2019). Data from telemetry studies around the SeaGen device in Strangford Lough, Northern Ireland, suggest that harbour seal may be exhibiting a degree of avoidance, with peaks in transit approximately 250m either side of the device (Sparling *et al*., 2016).

611. There is also uncertainty associated with the potential for a collision to result in fatality, and the potential physical effect of collision impacts on marine mammals. Thompson *et al.* (2016) and Onoufriou *et al*. (2019), carried out empirical tests with grey seal carcasses and concluded that collisions at blade speeds of 5.2 ms^{-1} or less did not result in any significant muscle or skeletal

damage and would be unlikely to result in serious injury or mortality. Incorporating this into the collision risk model (CRM) resulted in a reduction of predicted collision risk across a range of simulations of between 20% and 75%, depending on the proportion of predicted collisions which are below this speed. Above this speed, the probability of death or serious injury will increase with rotor speed, as will the likelihood of a collision. Therefore, rotor speeds and the relationship between rotor speed and current speed are clearly important factors. However, rotor speeds vary widely by device type and size. The size of moving parts, and therefore the area swept by them, is also an important determinant of the risk of collision. Larger blades sweep a larger area, putting a higher proportion of animals at risk of collision. However, larger blades are also likely to be slower than smaller blades and therefore collision probability will be lower for a given passage rate and animal speed. The variety in collision probability as a result of variation in different turbine parameters is therefore difficult to predict (Sparling and Smith, 2019).

612. The position of the devices in the water column will also have a significant effect on the predicted collision risk (Sparling and Smith, 2019). Therefore, the depth distribution of the marine mammals using a particular site is an important consideration and will often vary by species and potentially between sites. Many marine mammals are benthic foragers and divide their time primarily between the surface to breathe, and the seabed to feed, with relatively less time spent mid-water. For example, a study of grey seal juveniles tagged at Anglesey, Bardsey Island and Ramsey Sound found that tagged animals spent the majority of their time either at the surface or at the bottom of a dive with little time spent in the mid water depths (Thompson, 2012). Whereas other species may spend considerable time in other parts of the water column. For example, studies indicate that bottlenose dolphins may spent little time in waters deeper than 10m, based on a depth distribution for bottlenose dolphins obtained from a vertical array of hydrophones (Hastie *et al*., 2006) and dolphin dive data from satellite-linked, time–depth recorders (Corkeron and Martin, 2004; Klatsky *et al*., 2007; Sparling and Smith, 2019). Studies also indicate the harbour porpoises spent about half their time within the top 2m of the water column (Teilmann *et al*., 2007, 2013). Therefore, for species that spend a considerable amount of their time near the surface, such as bottlenose dolphins and harbour porpoises, TECs close to the surface would represent the worst-case scenario for collision risk. Whereas, where animals are foraging on the seabed, midwater devices with adequate clearance above and below could represent a lower risk than devices situated close to the seabed or the water surface (Sparling and Smith, 2019).

613. The total number of TECs is also be a major factor in determining collision risk. As outlined by Sparling and Smith (2019), currently there is no way of realistically modelling the collision risk posed by multiple devices, other than simply multiplying the risk for a single device by the total number of devices. However, this is likely to be unrealistic as it is difficult to predict how animals might respond to an array of devices. For example, the probability of avoidance is likely to be modified as a result of a close range encounters with preceding devices. There is the possibility that animals might learn from encountering and avoiding the first device and then subsequently avoid additional devices at a greater distance. However, there could also be the possibility that avoiding one device might bring an animal into the path of a subsequent device with an increased probability of collision, although this will depend on device spacing. Although collision risk may not scale linearly with the number of TECs in an array, given current uncertainty regarding marine mammal behaviour, and a lack of empirical data, most assessments make the assumption that there will be a linear increase in risk with the total number of devices installed.

614. There are a number of different features of tidal devices and arrays which can have an effect on the magnitude of potential collision risk for marine mammals (Sparling and Smith, 2019), including:

- The number and size of Tidal Energy Converters (TEC) moving parts (e.g. for horizontal axial flow designs; number of rotors and rotor dimensions and shape);
- The total number of devices with moving parts;
- The speed of movement of moving parts; and
- The position of TECs in the water column (in relation to the depth distribution of marine mammals).

615. These factors have been taken into account when determining the realistic worst-case parameters for the collision risk assessment, as outlined in **Section 12.6.4.5.1**.

12.6.4.5.1. Parameters used Collision Risk Assessment

12.6.4.5.1.1. CRM and ERM models

616. For the marine mammal collision risk assessment two methods, Encounter Rate Modelling (ERM) and Collision Risk Modelling (CRM), using the Scottish Natural Heritage guidance for assessing collision risk between underwater turbines and marine wildlife (SNH, 2016) and accompanying spreadsheets. This approach was agreed with NRW at the 2nd Marine Mammal TWG in February 2019.

617. The ERM, based on the work by the Scottish Association for Marine Science (SAMS) (Wilson *et al*., 2007), is designed to predict potential encounters with predator and prey. The model considers the volume swept by each rotor blade (predator) and the number of individuals (prey) present within that volume and estimates how many encounters on this basis and scales up to relevant time period. Key device parameters include number of rotors, number of blades, blade depth, blade length, rotation speed.

618. The CRM was originally developed as the “Band Model” to assess collision risk to flying birds with wind turbines. The model considers the number of animals likely to pass through each rotor, and the probability of collision for each such passage and estimates how many collisions on this basis and scales up to relevant time period. Key device parameters include number of rotors, number of blades, blade width, blade length, rotation speed.

619. The difference in the models and the parameters used result in different results for different devices and scenarios. Therefore, the collision risk assessments were conducted using both the ERM and CRM for all marine mammal species.

620. It should be noted, as acknowledged by SNH (2016), that the ERM and CRM methods will provide at best, an order of magnitude estimate of collision risk.

12.6.4.5.1.2. Tidal Devices and Array Scenarios

621. The tidal sector is an emerging industry with a wide range of technology types that are still being developed and optimised. As a result, Morlais may attract a wide spectrum of tidal devices over

the life of the project. The range and flexibility sought within the consent application has been limited by careful consideration of development scenarios designed to rationalise the likely approach to development and to set workable limits on potential impacts. As a result, a series of key design principles have been identified and used to shape the impact assessments undertaken. This approach allows a range or “envelope” of design parameters, and the likely worst case of each parameter, to be defined. This approach is tested in planning law and referred to as the ‘Rochdale Envelope’ approach, often called a Project Design Envelope (PDE).

622. It is important to note that because a wide range of designs at varying scales are currently available (and may be available in the future), the technologies referred to are provided as examples for reference only and are to be considered representative of the range of device types that could be utilised at Morlais. A review of these potential tidal technologies has allowed the identification of realistic worst-case parameters for each device type (as outlined in **Table 12-76**).

623. The worst-case parameters used to define the PDE in terms of the device parameters and the relevant worst-case scenarios for the Project have been used in the impact assessments.

624. The device types outlined represent the device type parameters which fall within the PDE. There are a number of novel device types available. The device types included in this assessment are deemed to represent the most suitable parameters for deployment at Morlais.

12.6.4.5.1.3. Marine Mammal Parameters

625. The density estimates and reference populations used in the assessments are presented in **Table 12-22**. These were agreed with NRW at the 2nd marine mammal TWG meeting on the 19th February 2019.

626. **Table 12-77** outlines the marine mammal dimensions, based on the SNH guidance (SNH, 2016), used for the collision risk assessment. The SNH guidance (SNH, 2016) does not provide data for dolphin species, therefore for bottlenose dolphin, Risso's dolphin and common dolphin these have been determined based on Cetacean Stranding's Investigation Programme (CSIP) strandings records from Wales and data collected by Marine Environmental Monitoring (1994-2017). Further details are provided in **Appendix 12.2** (**Volume III**).

Table 12-77 Marine mammal dimensions used in the Morlais collision risk assessments

Species	Length (m)	Effective radius/body width (m)	Source
Harbour porpoise	1.48m	0.32m	SNH (2016); Thompson (2015)
Bottlenose dolphin	2.57m	0.64m	Calculated from Welsh strandings data (1994-2017)
Risso's dolphin	2.36m	0.59m	Calculated from Welsh strandings data (1994-2017)
Common dolphin	1.77m	0.44m	Calculated from Welsh strandings data (1994-2017)
Minke whale	8.8m	2.2m	SNH (2016); Horwood (1990)
Grey seal	1.86m	0.42m	SNH (2016); Thompson (2015)
Harbour seal	1.41m	0.34m	SNH (2016)

627. **Table 12-78** outlines the marine mammal swim speeds and dive profiles, based on the SNH guidance (SNH, 2016) used for the Morlais collision risk assessments. The SNH guidance (SNH, 2016) does not provide data for dolphin species, therefore for bottlenose dolphin these have been determined based on other sources, where available. Currently there is no or limited suitable data for Risso's and common dolphin, so where required values for bottlenose dolphin have been used. Further details are provided in **Appendix 12.2** (**Volume III**).

Table 12-78 Marine mammal swim speeds and dive profile used in the Morlais collision risk assessments

Species	Mean swim speed (m/s)	Mean dive time (s)	Mean surface time (s)	Depth distribution type / dive profile	Source
Harbour porpoise	1.4m/s	26.2s	3.9s	Harbour porpoise	SNH (2016); Westgate *et al*. (1995); Otani *et al*. (2000)
Bottlenose dolphin	1.8m/s	25.8s	3.7s	Uniform	Skrovan *et al*. (1999); Mate *et al*. (1995)
Risso's dolphin	1.7m/s	25.8s	3.7s	Uniform	N/A based on BND parameters
Common dolphin	1.7m/s	25.8s	3.7s	Uniform	N/A based on BND parameters

Species	Mean swim speed (m/s)	Mean dive time (s)	Mean surface time (s)	Depth distribution type / dive profile	Source
Minke whale	2.1m/s	87s	3.5s	Uniform	SNH (2016); Williams (2009); Stern (1992)
Grey seal	1.8m/s	297s	165s	Grey seal	SNH (2016); Thompson (2015); Beck *et al*. (2000)
Harbour seal	1.8m/s	180s	39.5s	Harbour seal	SNH (2016); Thompson (2015); Thompson *et al.* (2014); Chudzinska (2009)

12.6.4.5.1.4. Avoidance Rates

628. As outlined in **Section 12.6.4.1**, underwater noise from operational turbines will be detected by marine mammals and has the potential to cause disturbance. However, given the potential for masking of the devices operational noise due to high background noise levels, 100% avoidance behaviour cannot be assumed to occur in response to tidal device noise.

629. EMEC (2014) assumed avoidance rates of 98% for harbour porpoise, 95-98% for minke whale, 98% for harbour and grey seal in the collision risk modelling at the Falls of Warness tidal site. Band (2015) recommends presenting collision risk results using a range of avoidance rates 0%, 50%, 95%, 98% and 99%.

630. Avoidance rates of 0%, 50%, 90%, 95%, 98% and 99% have been presented for all species in **Appendix 12.2** (**Volume III**). However, the assessment of the potential impacts and effects have been based on the avoidance rates in **Table 12-79**.

Table 12-79 Marine mammal avoidance rates used in the Morlais collision risk assessments

Species	Avoidance rate
Harbour porpoise	98%
Bottlenose dolphin	98%
Risso’s dolphin	98%
Common dolphin	98%
Minke whale	98%
Grey seal	98%
Harbour seal	98%

12.6.4.5.2. Collision Risk Assessments

631. The indicative scenarios conducted for the maximum number of each type of device combined where the predicted collision risk is less than one bottlenose dolphin, have been conducted for each species, with no mitigation. **Table 12-80** and **Table 12-81** provides indicative scenarios for the maximum number of each type of device combined for collision risk of less than one bottlenose dolphin, using the ERM and CRM (number of individuals per year and percentage of reference population), respectively, based on 98% avoidance.

632. The assessments are based on the indicative scenarios for the combination of different types of devices where the collision risk is predicted to be less than one bottlenose dolphin (based on the scenarios with the current maximum MW). Each stage of deployment would only progress based on updated assessments and that the regular reviewing of the monitoring and mitigation indicated that there was no increased collision risk.

633. The approach will be to deploy to a level where the risk is less than one bottlenose dolphin. This deployment will then be monitored with mitigation, such as the use of ADDs if animals come too close to the tidal devices and arrays. The next phase of deployment would only proceed when a review of the monitoring and requirements for mitigation (e.g. how often ADDs were activated), indicates that there is no increased collisions risk. This would be done through the adaptive management and mitigation plan (EMMP) and in consultation with NRW. Therefore, the assessments, including the in-combination assessment, is based on the scenarios for less than one bottlenose dolphin, as this would be the worst-case scenario.

634. **Section 12.6.4.5.3** outlines the proposed monitoring and mitigation for the phased deployments.

635. It is important to note that the output of the devices (MW) used in the assessments are indicative and have been based on the current minimum rating, as a worst-case scenario and prior to deployment it is expected that the rating (MW) for the devices deployed would be higher, although the other parameters are unlikely to change. Further assessments will be conducted prior to deployment as part of the adaptive management and mitigation plan (EMMP; **Document MOR/RHDHV/DOC/0072**).

636. In addition to the indicative scenarios conducted for the maximum number of each type of device combined where the predicted collision risk is less than one bottlenose dolphin in **Table 12-82**, **Table 12-83** outlines the maximum number of each type of device for one device type only, where the predicted collision risk is less than one bottlenose dolphin. Further details on the assessment of these scenarios for the different species are presented in **Appendix 12.2** (**Volume III**).

637. Indicative assessments for 30MW and 40MW of each type of device and an indicative 240MW scenario are also presented in **Appendix 12.2** (**Volume III**), however, these would only be developed once the monitoring and mitigation indicates that the collision risk would be less than one bottlenose dolphin.

Table 12-84 Number of individuals (and % of reference population) that could be at risk of collision with operational tidal devices at Morlais (based on scenarios for less than one bottlenose dolphin)

Species	Magnitude (ERM and CRM)
Harbour porpoise	20-23 individuals (0.02% of MU). Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.99 individuals (0.25% of MU). Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Risso's dolphin	1.4 individuals (0.02% of MU). Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Common dolphin	8 individuals (0.01% of MU) Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Minke whale	2-3 individuals (0.01%) Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Grey seal	4-5 individuals (0.08% of MU) Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).
Harbour seal	0.01 individuals (0.03% of MU) Potential permanent effect with medium magnitude (0.01-1% of the reference population anticipated to be exposed to effect).

638. As for increased collision risk with vessels, the sensitivity has been assessed as low for all marine mammal species. This has been determined based on no incidents reported for marine mammals with any operational tidal devices, the ability of marine mammal to detect the physical structures of the devices before they encounter the blades and the underwater noise generated by the operational devices, even with high ambient noise levels. The sensitivity classification of the Welsh marine mammal populations from Sparling *et al*. (2015), as outlined in **Section 12.5.11** and **Table 12-23** has also been included for context.

639. Taking into account the sensitivity and the potential magnitude of the effect for the different scenarios, the impact significance for any permanent impacts on harbour porpoise, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal has been assessed as **minor (not significant)** (**Table 12-85**).

640. The number of animals that can be 'removed' from a population varies but is largely dependent on the growth rate of the population; populations with low growth rates can

sustain the removal of a smaller proportion of the population. The JNCC *et al*. (2010) draft EPS guidance provides some indication on how many animals may be removed from a population without causing detrimental effects to the population at FCS.

641. JNCC *et al*. (2010) draft EPS guidance considered 4% as the maximum potential growth rate in harbour porpoise, and the 'default' rate for cetaceans. Therefore, beyond natural mortality, up to 4% of the population could theoretically be permanently removed before population growth would be halted.

642. The collision risk assessments have been based on the worst-case scenarios, does not take into account the proposed phased deployment, monitoring and mitigation measures and assumes that all encounter or collisions would be fatal.

643. Taking this into account, along with the JNCC *et al*. (2010) draft EPS guidance, it is therefore unlikely that the potential collision risk would result in any significant population effects for bottlenose dolphin, harbour porpoise, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal.

644. A threshold of 1.7% of the relevant harbour porpoise population above which a population decline is inevitable has been agreed with Parties to the Agreement on the Conservation of Small Cetaceans of the Baltic and North Seas (ASCOBANS), with an intermediate precautionary objective of reducing the impact to less than 1% of the population (Defra, 2003; ASCOBANS, 2015). This threshold relates to impacts from fisheries by-catch on harbour porpoise where the impact on the harbour porpoise is permanent, i.e. up to 1.7% of the population may be caught as by-catch before a population decline is inevitable.

645. The percentage of the reference population that could be at risk of collision with operational tidal devices at Morlais, based on scenarios for less than one bottlenose dolphin scenarios, is considerably less than 1.7% for bottlenose dolphin, harbour porpoise, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal, with a maximum of 0.25% or less of the reference population for bottlenose dolphin (**Table 12-84**).

646. As outlined in **Section 12.6.4.5.5**, the potential population level effects of collision risk with operational tidal turbines on marine mammals have been assessed in **Appendix 12.2** (**Volume III**). The result of the PVA indicate that population trajectories of the baseline and collision risk scenarios of 1, 2 and 3 animals are very similar, with only a potential for a decline when more than three adults per year are removed from the population of 397 bottlenose dolphins in the Irish Sea MU.

Table 12-85 Assessment of impact significance for collision risk with operational turbines at MDZ

Potential Impact	Receptor	Sensitivity (sensitivity of Welsh population)	Magnitude	Significance	Mitigation	Residual Impact
Collision risk for less than one bottlenose dolphin scenarios	Harbour porpoise	Low (Low)	Medium	Minor	Phased deployment, monitoring and mitigation (EMMP)	Minor (not significant)
	Bottlenose dolphin	Low (High)	Medium	Minor		Minor (not significant)
	Risso's dolphin	Low (Low)	Medium	Minor		Minor (not significant)
	Common dolphin	Low (Low)	Medium	Minor		Minor (not significant)
	Minke whale	Low (Low)	Medium	Minor		Minor (not significant)
	Grey seal	Low (Low)	Medium	Minor		Minor (not significant)
	Harbour seal	Low (Low)	Medium	Minor		Minor (not significant)

12.6.4.5.3. Mitigation

647. As outlined in **Section 12.6.2**, the deployment, monitoring and adaptive management plan will be developed in the pre-construction period and based upon best available information, methodologies, industry best practice, latest scientific understanding, current guidance and detailed project design.

648. This plan will consider the most suitable and effective monitoring and mitigation measures to, detect marine mammals in and around the arrays (for example, using remotely monitored PAM, underwater cameras, autonomous recorders, and / or high definition (HD) and thermal imaging camera systems). There would also be the use of active sonar to detect marine mammals in close proximity to the arrays / devices to trigger mitigation measures, such as the automatic activation of ADDs to deter marine mammals from a predetermined mitigation zone around the arrays / devices.

649. The approach would be based on deployment, monitoring and adaptive management, with regular reviews of the installation at appropriate increments directly related to collision risk to marine mammals, specially bottlenose dolphin, to ensure that in that no more than one bottlenose dolphin could be at risk.

12.6.4.5.4. Residual Impacts

650. With the effective and appropriate mitigation proposed any risk of collisions will be greatly reduced. As a precautionary approach the residual impacts have been assessed as minor (not significant) for most species and a very precautionary minor to moderate for bottlenose dolphin and the 30MW and 240MW scenarios. Although is expected to be lower, taking into account that bottlenose dolphins have not been

recorded in the MDZ and are more likely to move along the coast than through the MDZ array area.

12.6.4.5.5. Assessment of Potential Population Level Effects

651. The potential population level effects of collision risk with operational tidal turbines on marine mammals have been assessed in **Appendix 12.3**.

652. The potential population effects have been assessed in a separate appendix as this will continue to be updated and developed as part of the mitigation and monitoring plan (**Document MOR/RHDHV/DOC/0072**).

12.6.4.6. Increased Collision Risk with Vessels

653. Although impacts will be less than during construction, as a worst-case scenario assessment has been based on assessment for construction in **Section 12.6.3.6**.

654. The potential for increased collision risk with vessels has been based on up to 16 vessels on site at any one time, with up to 16 vessel movements to and from the site per day. The maximum area of potential risk has been estimated based on construction vessels in indicative examples of the two largest potential deployment areas (3 km^2 and 3 km^2); plus, vessels in ECC area (4.75 km^2). In addition, increased collision risk has also been estimated based on the potential vessel route area to and from Holyhead Harbour, based on a precautionary 250m buffer either side of the vessels (**Table 12-86**).

Table 12-86 Estimated number of individuals (and % of reference population) that could be at increased collision risk with vessels at MDZ

Species	Increased collision risk (5-10% of individuals in area at increased risk)			
	Two indicative deployment areas and cable corridor (10.75 km^2) area.	**Vessel route to Holyhead Port (4.34 km^2)**	**Number of individuals (% of reference population) at potential increased risk in total area (15.09 km^2)**	**Magnitude**
Harbour porpoise	0.42-0.84 individuals (based on density estimate of 0.783/ km^2) (0.0004-0.008% of the 104,695 reference population).	0.17-0.34 individuals (based on density estimate of 0.783/ km^2) (0.0002-0.0003% of the 104,695 reference population).	0.59-1.18 individuals (0.0006-0.0011% of MU)	Potential permanent effect with negligible to low magnitude (0.01% or less of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.011-0.022 individuals (based on density estimate of 0.02/ km^2)	0.0043-0.009 individuals (based on density estimate of 0.02/ km^2) (0.0011-0.0022% of the reference	0.015-0.031 individuals (0.0038-0.0076% of MU)	Potential permanent effect with low magnitude (between 0.001% and 0.01% of the

Species	Increased collision risk (5-10% of individuals in area at increased risk)			
	Two indicative deployment areas and cable corridor (10.75 km²) area.	**Vessel route to Holyhead Port (4.34 km²)**	**Number of individuals (% of reference population) at potential increased risk in total area (15.09 km²)**	**Magnitude**
	(0.003-0.0054% of the reference population of 397 bottlenose dolphin)	population of 397 bottlenose dolphin)		reference population anticipated to be exposed to effect).
Risso's dolphin	0.017-0.033 individuals (based on density estimate of 0.031/ km²) (0.0002-0.0004% of the reference population of 8,794 Risso's dolphin).	0.007-0.014 individuals (based on density estimate of 0.031/ km²) (0.0001-0.0002% of the reference population of 8,794 Risso's dolphin).	0.024-0.047 individuals (0.0003-0.0005% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
Common dolphin	0.12-0.24 individuals (based on density estimate of 0.22/ km²) (0.0002-0.0004% of the reference population of 56,556 common dolphin).	0.05-0.096 individuals (based on density estimate of 0.22/ km²) (0.0001-0.0002% of the reference population of 56,556 common dolphin).	0.17-0.336 individuals (0.0003-0.0006% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
Minke whale	0.009-0.02 individuals (based on density estimate of 0.017/ km²) (0.00004-0.0001% of the reference population of 23,528 minke whale).	0.004-0.007 individuals (based on density estimate of 0.017/ km²) (0.00002-0.00003% of the reference population of 23,528 minke whale).	0.013-0.027 individuals (0.0001-0.0001% of MU)	Potential permanent effect with negligible / very low magnitude (less than 0.001% of the reference population anticipated to be exposed to effect).
Grey seal	0.083-0.17 individuals (based on density estimate of 0.155/ km²) (0.0014-0.003% of the reference population of 6,000 grey seal).	0.034-0.067 individuals (based on density estimate of 0.155/ km²) (0.0006-0.0011% of the reference population of 6,000 grey seal).	0.117-0.237 individuals (0.0019%-0.0039% of MU)	Potential permanent effect with negligible to low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Harbour seal	0.0003-0.0005 individuals (based on density estimate of 0.0005/ km²) (0.0005-0.0011% of the reference	0.0001-0.0002 individuals (based on density estimate of 0.0005/ km²) (0.0002-0.0004% of the reference	0.0004-0.0007 individuals (0.0008-0.0015% of MU)	Potential permanent effect with negligible to low magnitude (0.01% or less of the reference population

Species	Increased collision risk (5-10% of individuals in area at increased risk)			
	Two indicative deployment areas and cable corridor (10.75 km^2) area.	**Vessel route to Holyhead Port (4.34 km^2)**	**Number of individuals (% of reference population) at potential increased risk in total area (15.09 km^2)**	**Magnitude**
	population of 50 harbour seal).	population of 50 harbour seal).		anticipated to be exposed to effect).

655. Taking into account the low sensitivity of all marine mammal species to increased collision risk with vessels and the potential magnitude of the effect (negligible or low for all species), the impact significance for any permanent impact on harbour porpoise, bottlenose dolphin, grey seal and harbour seal has been assessed as **minor (not significant)** and **negligible** for Risso's dolphin, common dolphin and minke whale (**Table 12-87**).

12.6.4.6.1. Mitigation

656. Where possible, all vessel movements will be kept to the minimum number that is required to reduce any potential collision risk. Additionally, vessel operators will use good practice to reduce any risk of collisions with marine mammals. No further mitigation is proposed.

12.6.4.6.2. Residual Impact

657. The residual impact would remain negligible or minor (not significant).

Table 12-87 Assessment of impact significance for increased collision risk with vessels at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Increased collision risk with vessels	Harbour porpoise	Low	Negligible to low	Negligible to minor (not significant)	No mitigation is required or proposed	Negligible to minor (not significant)
	Bottlenose dolphin		Low	Minor (not significant)		Minor (not significant)
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Negligible to low	Negligible to minor (not significant)		Negligible to minor (not significant)

12.6.4.7. Potential Overall Collision Risk for Operational Turbines and Vessels

658. As a precautionary approach the number of marine mammals (and percentage of the reference populations) has been assessed for the potential collision risk with operational turbines (**Section 12.6.4.5.2**) and possible increased collision risk with vessels (**Section 12.6.4.6**).

659. The assessment has been based on the worst-case scenario that there could be up to 16 vessels on site at the same time as the scenario for less than one bottlenose dolphin (**Table 12-88**). However, it is highly unlikely that 16 vessels would be on site during operation, also when vessels are on site during operation this is likely to be for maintenance and repowering activities, which would result in a number of devices to be non-operational during these activities.

Table 12-88 Estimated number of individuals (and % of reference population) that could be at increased collision risk with vessels and operational tidal devices at MDZ (based on scenarios for less than one bottlenose dolphin)

Species	Number of individuals (% of reference population)			Magnitude
	Increased collision risk with vessels (5-10% of individuals in total area; 15.09 km^2)	**Collision risk for one bottlenose dolphin scenario (ERM and CRM)**	**Total (maximum based on worst-case scenario)**	
Harbour porpoise	0.59-1.18 individuals (0.0006-0.0011% of MU)	20-23 individuals (0.02% of MU).	Up to 25 individuals (0.024%)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.015-0.031 individuals (0.0038-0.0076% of MU)	0.99 individuals (0.25% of MU)	Up to 1 individual (0.25% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Risso's dolphin	0.024-0.047 individuals (0.0003-0.0005% of MU)	1.4 individuals (0.02% of MU)	Up to 1.5 individuals (0.02% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).

Species	Number of individuals (% of reference population)			Magnitude
	Increased collision risk with vessels (5-10% of individuals in total area; 15.09 km^2)	Collision risk for one bottlenose dolphin scenario (ERM and CRM)	Total (maximum based on worst-case scenario)	
Common dolphin	0.17-0.336 individuals (0.0003-0.0006% of MU)	8 individuals (0.01% of MU)	Up to 9 individuals (0.02% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Minke whale	0.013-0.027 individuals (0.0001-0.0001% of MU)	2-3 individuals (0.01%)	Up to 3 individuals (0.01% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Grey seal	0.117-0.237 individuals (0.0019%-0.0039% of MU)	4-5 individuals (0.08% of MU)	Up to 5 individuals (0.08% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Harbour seal	0.0004-0.0007 individuals (0.0008-0.0015% of MU)	0.01 individuals (0.03% of MU)	Less than 1 individual (0.03% of MU)	Potential permanent effect with **medium** magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).

660. Taking into account the sensitivity and the potential magnitude of the effect the impact significance for any permanent impacts on harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal has been assessed as **minor (not significant)**, without mitigation (**Table 12-89**).

661. As outlined in **Section 12.6.4.5.5**, the potential population level effects of collision risk with operational tidal turbines on marine mammals have been assessed in **Appendix 12.2** (**Volume III**). The result of the PVA indicate that population trajectories of the baseline and collision risk scenarios of 1, 2 and 3 animals are very similar, with only a

potential for a decline when more than three adults per year are removed from the population of 397 bottlenose dolphins in the Irish Sea MU.

12.6.4.7.1. Mitigation

662. As outlined in **Section 12.6.2** and **12.6.4.5.3**.

12.6.4.7.2. Residual Impacts

663. With the effective and appropriate mitigation proposed any risk of collisions will be greatly reduced. As a precautionary approach the residual impacts have been assessed as minor (not significant) for all species.

Table 12-89 Assessment of impact significance for potential overall collision risk with vessels and operational turbines at MDZ (based on scenarios for less than one bottlenose dolphin)

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Maximum overall collision risk with vessels and operational turbines	Harbour porpoise	Low	Medium	Minor	Phased deployment, monitoring and mitigation	Minor (not significant)
	Bottlenose dolphin		Medium	Minor		Minor (not significant
	Risso's dolphin		Medium	Minor		Minor (not significant)
	Common dolphin		Medium	Minor		Minor (not significant)
	Minke whale		Medium	Minor		Minor (not significant)
	Grey seal		Medium	Minor		Minor (not significant)
	Harbour seal		Medium	Minor		Minor (not significant)

12.6.4.8. Potential Entanglement with Moorings

664. To date, there have been no recorded instances of marine mammal entanglement from mooring systems of renewable devices (Sparling *et al*., 2013; Isaacman and Daborn, 2011), or for anchored floating production, storage and offloading (FPSO) vessels in the oil and gas industry (Benjamins *et al*., 2014) with similar mooring lines.

665. The level of risk to become entangled varies with species (Benjamins *et al*., 2014), these factors include:

- Body size;
- Flexibility of movement;
- The ability to detect mooring lines and ropes; and
- The feeding ecology of the species.

666. Toothed whales have a lower risk than baleen whales, primarily due to their small size and manoeuvrability. Seal species have a similar risk level to small toothed cetaceans, with an increase in manoeuvrability.

667. Benjamins *et al*. (2014) provides a qualitative assessment of relative entanglement risk across different marine megafauna groups, taking into account both biological risk factors such as animal size, sensory capabilities and foraging methods, and physical risk factors such as mooring flexibility, pre-tension and footprint. **Table 12-90** summarises the results of this assessment.

Table 12-90 Relative risk assessment for marine mammals and mooring scenarios relevant to the Morlais site (based on biological and physical risk parameters; Benjamins *et al.*, 2014)

Species	Catenary & chain	Taut & accessory buoy
Harbour porpoise	Low	Low
Bottlenose dolphin	Low	Low
Risso's dolphin	Low	Low
Common dolphin	Low	Low
Minke whale	High	High
Grey seal	Low	Low
Harbour seal	Low	Low

668. Taking into account that there have been no recorded instances of marine mammal entanglement from mooring systems of renewable devices or similar mooring lines, the sensitivity of marine mammals to potential entanglement at the MDZ is assessed to be low.

669. In addition, the tidal devices and moorings would be regular checked (approximately 15 times annually for both planned and unplanned maintenance activities), this would ensure that there was no material such as discarded nets, ropes or other debris which could increase the risk of entanglement for marine mammals or interfere with the optimal operation of the tidal devices.

670. As a precautionary approach, the potential magnitude of effect has been based on the on the relative risk assessment for marine mammals by Benjamins *et al*. (2014) for the mooring scenarios which most represent those likely to be used at MDZ (i.e. catenary & chain and taut & accessory buoy) (**Table 12-90**).

671. The impact significance for the possible entanglement with mooring lines disturbance has been assessed as minor for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, grey and harbour seal and minor to moderate for minke whale (**Table 12-91**).

12.6.4.8.1. Mitigation

672. The mitigation and monitoring measures to reduce the risk of collision with operational turbines would also reduce the risk of entablement with mooring lines.

12.6.4.8.2. Residual Impact

673. As a precautionary approach the residual impacts have been assessed as minor (not significant) for all species.

Table 12-91 Assessment of impact significance for possible entanglement of marine mammals with mooring lines at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Entanglement with mooring lines	Harbour porpoise	Low	Low	Minor	Phased deployment, monitoring and mitigation	Minor (not significant)
	Bottlenose dolphin		Low	Minor		Minor (not significant)
	Risso's dolphin		Low	Minor		Minor (not significant)
	Common dolphin		Low	Minor		Minor (not significant)
	Minke whale		Low to High	Minor to Moderate		Minor (not significant)
	Grey and harbour seal		Low	Minor		Minor (not significant)

12.6.4.9. Potential Electromagnetic Field (EMF) Effects

674. Potential pathways for effects from electromagnetic fields (EMF) would be from the presence of cables within the MDZ and ECC.

675. Normandeau *et al*. (2011) modelled expected magnetic fields using design characteristics taken from a range of undersea cable projects. For eight of the ten AC cables modelled it was found that the intensity of the magnetic field (B) was approximately a direct function of voltage (ranging from 33kV to 345kV) although separation between the cables and burial depth also influenced field strengths. Similarly, the modelling carried out for nine DC cables also found that the B field was a function of voltage (ranging from 75 to 500kV) and cable configuration. For both AC and DC cables, the predicted B fields were strongest directly over the cables and decreased rapidly with vertical and horizontal distance from the cables (**Table 12-92**).

Table 12-92 Averaged magnetic field strength values from AC and DC cables buried 1m (Normandeau *et al.*, 2011)

Distance (m) below seabed	Magnetic Fields Strength (μT)					
	Horizontal distance (m) from cable					
	0m AC	0m DC	4m AC	4m DC	10m AC	10m DC
0	7.85	78.27	1.47	5.97	0.22	1.02
5	0.35	2.73	0.29	1.92	0.14	0.75
10	0.13	0.83	0.12	0.74	0.08	0.46

676. Although it is assumed that marine mammals are capable of detecting small differences in magnetic field strength, this is unproven and is based on circumstantial information. There is also, at present, no evidence to suggest that existing subsea cables have influenced cetacean or seal movements. For example, harbour porpoise move in and out of the Baltic Sea with several crossings over operating subsea HVDC cables in the Skagerrak and western Baltic Sea without any apparent effect on their migration pattern. There is no evidence that pinnipeds respond to electromagnetic fields (Gill *et al*., 2005).

677. In addition, data from operational windfarms show no evidence of exclusion of marine mammals, such as harbour porpoise or seals (for example, Diederichs *et al*., 2008; Lindeboom *et al*., 2011; Marine Scotland, 2012; McConnell *et al*., 2012; Russell *et al*., 2014; Scheidat *et al*., 2011; Teilmann *et al*., 2006; Tougaard *et al*., 2005, 2009a, 2009b).

678. Therefore, harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey and harbour seal have been assessed as having negligible sensitivity to any potential EMF effects.

679. The number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be affected by any potential EMF effects have been assessed based on the cable area (0.042 km^2; **Table 12-25**) in the MDZ and ECC (**Table 12-93**).

Table 12-93 Number of individuals (and % of reference population) that could be affected by any potential EMF effects

Species	Maximum number of individuals and (% of reference population)	Magnitude
Harbour porpoise	0.03 individuals (based on density estimate of 0.783/ km^2) (0.00003% of the 104,695 reference population).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.001 individuals (based on density estimate of 0.02/ km^2) (0.0002% of the reference population of 397 bottlenose dolphin).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Risso's dolphin	0.001 individuals (based on density estimate of 0.031/ km^2) (0.00001% of the reference population of 8,794 Risso's dolphin).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Common dolphin	0.01 individuals (based on density estimate of 0.22/ km^2) (0.00002% of the reference population of 56,556 common dolphin).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Minke whale	0.001 individuals (based on density estimate of 0.017/ km^2) (0.000003% of the reference population of 23,528 minke whale).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Grey seal	0.01 individuals (based on density estimate of 0.155/ km^2)	Long-term effect with negligible magnitude (less than 0.01% of the

Species	Maximum number of individuals and (% of reference population)	Magnitude
	(0.0001% of the reference population of 6,000 grey seal).	reference population anticipated to be exposed to effect).
Harbour seal	0.00002 individuals (based on density estimate of 0.0005/ km^2) (0.00004% of the reference population of 50 harbour seal).	Long-term effect with negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).

680. The magnitude of the potential for any EMF effects is assessed as **negligible** for all species, with less than 0.01% of all relevant reference populations anticipated to be exposed to the long-term effect (**Table 12-35**).

681. Taking into account the negligible sensitivity of all marine mammal species and the potential negligible magnitude of the effect, the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any long-term effects over the duration of the Project has been assessed as **negligible** (**Table 12-94**).

12.6.4.9.1. Mitigation

682. No mitigation measures are required or proposed.

12.6.4.9.2. Residual Impact

683. The residual impact would remain negligible.

Table 12-94 Assessment of impact significance for possible EMF on marine mammals

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
EMF effects	Harbour porpoise	Negligible	Negligible	Negligible	No mitigation required.	Negligible
	Bottlenose dolphin		Negligible	Negligible		Negligible
	Risso's dolphin		Negligible	Negligible		Negligible
	Common dolphin		Negligible	Negligible		Negligible
	Minke whale		Negligible	Negligible		Negligible
	Grey and harbour seal		Negligible	Negligible		Negligible

12.6.4.10. Potential Barrier Effects

684. The physical presence of the tidal array could have the potential to create a physical barrier, preventing movement or migration of marine mammals between important

feeding and / or breeding areas, or potentially increasing swimming distances if marine mammals avoid the site and go around it.

685. As outlined in **Chapter 4, Project Description**, the final array layout will be identified post consent, following the berth selection and allocation process. The final detailed device locations will be developed based on further site investigation works conducted post-consent to determine detailed construction constraints. However, the assessment has been based on indicative spacings and potential area of the tidal arrays.

686. Seabed mounted devices may have a spacing of 70m to 150m between centres of devices perpendicular to the flow and 180m to 250m parallel to the flow. Such spacings may need to be modified to allow for seabed conditions, and this could alter spacings considerably, resulting in larger spacings.

687. Floating tidal devices sharing moorings may require up to 150m between structure centres perpendicular to the flow and 250m parallel to the flow.

688. Each device could move by up to 80m (±40m) in the direction parallel to the flow and 60m (±30m) in the direction perpendicular to the flow. Therefore, the overall surface area covered by device movement (including device yawing) is up to 4,800m^2 for a single floating device.

689. This equates to a maximum area taken up by all arrays, including spaces between devices (i.e. not the seabed footprint) of up to 12.5 km^2 for the full 240MW capacity project (**Table 12-25**).

690. As illustrated by the three indicative layouts (each totalling 240MW), each with a different combination of device arrays (sub-categories) in different locations, as outlined in **Chapter 4, Project Description**, there would be space between the different deployment areas and the rows of tidal arrays in each deployment areas.

691. The number of harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal that could be at risk of potential barrier effects has been based on the maximum area of 12.5 km^2 (**Table 12-95**).

692. As for underwater noise, the sensitivity of marine mammals to any disturbance or displacement has been assessed as low.

693. The magnitude of the potential impact is assessed as low or negligible with less than 0.01% or 1% of all relevant reference populations anticipated to be exposed to the long-term effect (**Table 12-95**).

Table 12-95 Number of individuals (and % of reference population) that could be impacted by any potential barrier effects from the physical presence of the tidal arrays

Species	Maximum number of individuals and (% of reference population)	Magnitude
Harbour porpoise	Up to 10 individuals (based on density estimate of 0.783/ km^2) (0.01% of the 104,695 reference population).	Long-term effect with low magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Bottlenose dolphin	0.25 individuals (based on density estimate of 0.02/ km^2) (0.063% of the reference population of 397 bottlenose dolphin).	Long-term effect with low magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Risso's dolphin	0.4 individuals (based on density estimate of 0.031/ km^2) (0.005% of the reference population of 8,794 Risso's dolphin).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Common dolphin	Up to 3 individuals (based on density estimate of 0.22/ km^2) (0.005% of the reference population of 56,556 common dolphin).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Minke whale	0.2 individuals (based on density estimate of 0.017/ km^2) (0.0009% of the reference population of 23,528 minke whale).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Grey seal	Up to 2 individuals (based on density estimate of 0.155/ km^2) (0.03% of the reference population of 6,000 grey seal).	Long-term effect with low magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Harbour seal	0.006 individuals (based on density estimate of 0.0005/ km^2) (0.012% of the reference population of 50 harbour seal).	Long-term effect with low magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).

694. There is unlikely to be any potential barrier effects that could significantly affect the movements of marine mammals in or through the MDZ and ECC area. The maximum area for disturbance and any displacement from any barrier effects is relatively small in relation to the marine mammal MUs.

695. The potential for displacement is also unlikely to result in any significant increase in energy expenditure that could be required by harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal to avoid the area.

696. Taking into account the low sensitivity to any disturbance or displacement (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of effect, the impact significance (based on the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any potential barrier effects for harbour porpoise, bottlenose dolphin, grey seal and harbour seal has been assessed as minor and for Risso's dolphin, common dolphin and minke whale as negligible (**Table 12-96**).

12.6.4.10.1. Mitigation

697. The proposed phased development and monitoring measures to reduce the risk of collision with operational turbines would also allow the potential for any displacement effects, e.g. changes in use of the site or movements in and around the site, to be assessed, and if required, be taken into account for the installation of subsequent arrays.

12.6.4.10.2. Residual Impact

698. As a precautionary approach the residual impact would remain negligible or minor (not significant).

Table 12-96 Assessment of impact significance for any disturbance and displacement for any barrier effects at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Barrier effects	Harbour porpoise	Low	Low	Minor	None required or proposed	Minor (not significant)
	Bottlenose dolphin		Low	Minor		Minor (not significant)
	Risso's dolphin		Negligible / very low	Negligible		Negligible
	Common dolphin		Negligible / very low	Negligible		Negligible
	Minke whale		Negligible / very low	Negligible		Negligible
	Grey and harbour seal		Low	Minor		Minor (not significant)

12.6.4.11. Potential Changes in Water Quality

699. During the operational phase of the project there is a potential risk to water quality via accidental spillage or release of materials such as grease and oils during maintenance work, from vessels or during any major cable repair works and/or repowering activities.

700. As outlined for construction, Menter Môn is committed to the use of best practice and pollution prevention guidelines at all times. An MPCP would be in place and agreed with NRW in line with the IPPC Directive such that any potential risk is minimised. Any permitted discharges would be small volumes, intermittent and dilute and disperse quickly.

701. As for the construction phase, if any such substances were accidentally released/leaked, quantities would likely be small due to relatively small amounts being present in individual devices. Due to the dynamic nature of the tidal and wave regime in and around the MDZ, lateral and vertical dispersion rates of any spilled substances would be expected to be high. For the assessment in **Chapter 8, Marine Water and**

Sediment Quality, the magnitude of this potential effect was considered to be low, as it is not anticipated to significantly affect local water quality and would also be temporary in nature (established controls would prevent further spillage/leakage once an event was detected. Therefore, any changes to water quality was assessed as a minor adverse impact.

702. During the operational phase of the project repowering of devices will occur. As a worst-case scenario, it has been assumed that up to 50 % of all devices will be replaced (repowered) over the lifetime of the project. In addition, it has been assumed that there would be up to 10 cable repair events, totalling up to 7,500m of cable disturbance.

703. These activities will create similar effects as previously assessed for the construction phase. The potential removal and re-installation of seabed mounted devices and/or seabed anchor systems for floating devices coupled with potential cable de-burial and re-burial in sedimentary areas will all result in creation of localised sediment plumes and subsequent deposition. The magnitude of this effect will be less than for the main construction phase due to a lower amount of seabed disturbance via these operational phase activities. Therefore, for assessment in **Chapter 8, Marine Water and Sediment Quality**, the magnitude was assessed as negligible, resulting in a negligible impact.

704. As outlined in **Chapter 8, Marine Water and Sediment Quality**, placing any structure on the seabed has the potential to result in scour around the structure, leading in turn to mobilisation of any available sediment in the area around the structure via plumes.

705. In areas of the MDZ where the sea bed is comprised of bare bedrock or where this is covered with boulders, cobbles or gravels there is unlikely to be any scouring effects, therefore there will be no change in suspended sediment concentrations. Where devices are placed in areas of the MDZ characterised by sands (e.g. southwest section and in the vicinity of the sand ridge in the north) there is potential for locally accelerated flows around foundations to increase suspended sediment concentrations, but since flows in these areas are very high in the baseline conditions, this will unlikely to result in any significant change from the current conditions. Therefore, given the nature of the sea bed morphology, comprised mostly of exposed bedrock, the potential for adverse effects of this nature is extremely limited.

706. For the majority of the site, where sediment cover is absent/limited, **Chapter 8, Marine Water and Sediment Quality** assessed the magnitude of this effect to be negligible, with a negligible impact.

707. In areas where there is some sediment cover and, thus where scour may occur, the magnitude of effect was assessed to be low, resulting in a minor adverse impact.

708. As for construction, taking into account the negligible sensitivity of all marine mammal species to any changes in water quality and the potential magnitude of the effect (negligible or low), the impact significance for any temporary impact on harbour

porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale grey seal and harbour seal has been assessed as negligible (**Table 12-97**).

12.6.4.11.1. Mitigation

709. As outlined for construction and in **Chapter 8, Marine Water and Sediment Quality**, mitigation would include adherence to project-specific Environmental Management Plans (EMPs) and Marine Pollution Contingency Plans (MPCP). No further mitigation for marine mammals in proposed.

12.6.4.11.2. Residual Impact

710. The residual impact would remain negligible.

Table 12-97 Assessment of impact significance for any changes in water quality during operation

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Change in water quality due to sediment plumes generated by repowering and/or cable repair works	Harbour porpoise	Negligible	Negligible	Negligible	EMP and MPCP	Negligible
	Bottlenose dolphin		Negligible	Negligible		Negligible
	Risso's dolphin		Negligible	Negligible		Negligible
	Common dolphin		Negligible	Negligible		Negligible
	Minke whale		Negligible	Negligible		Negligible
	Grey and harbour seal		Negligible	Negligible		Negligible
Change in water quality due to sediment plumes produced via scour around seabed mounted project infrastructure	Harbour porpoise	Negligible	Negligible to Low	Negligible		Negligible
	Bottlenose dolphin		Negligible to Low	Negligible		Negligible
	Risso's dolphin		Negligible to Low	Negligible		Negligible
	Common dolphin		Negligible to Low	Negligible		Negligible
	Minke whale		Negligible to Low	Negligible		Negligible
	Grey and harbour seal		Negligible to Low	Negligible		Negligible
Change in water quality due to accidental	Harbour porpoise	Negligible	Low	Negligible		Negligible
	Bottlenose dolphin		Low	Negligible		Negligible

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
spillages/leaks from operational devices	Risso's dolphin		Low	Negligible		Negligible
	Common dolphin		Low	Negligible		Negligible
	Minke whale		Low	Negligible		Negligible
	Grey and harbour seal		Low	Negligible		Negligible

12.6.4.12. Potential Changes in Prey Availability

711. In **Chapter 10, Fish and Shellfish Ecology**, the potential impacts assessed for the operational and maintenance phase were

- Underwater Noise;
- Long-term habitat loss via placement of project infrastructure (project footprint);
- Barrier Effects;
- Collision Risk;
- Electromagnetic Fields; and
- Repowering.

12.6.4.12.1. Prey Impacts from Underwater Noise of Operational Turbines

712. The underwater noise assessment in **Chapter 10, Fish and Shellfish Ecology** was based on the modelling conducted for operational noise for the PTEC project, for 24m rotor (worst case scenario for the PTEC project). The largest range at which a behavioural reaction was predicted (i.e. levels of 75 dB_{ht} are reached) was 36m, for cod species. The largest range at which a startle response was predicted (i.e. levels of 90 dB_{ht} are reached) was 3m, also for cod.

713. These ranges are less than those predicted for marine mammal species (**Table 12-64**), therefore there will be no further impact on marine mammals as a result of any changes in prey availability due to underwater noise from operational turbines, as marine mammals will be displaced from the area that any changes in prey distribution could occur.

12.6.4.12.2. Prey Impacts from Permanent Habitat Loss

714. As outlined in **Chapter 10 Fish and Shellfish Ecology** and in **Table 12-25**, the worst-case scenario for permanent habitat loss would be up to 2.18 km^2, based on area for Gravity Base Structures (GBS) (74,790m^2), swept area of catenary cables (2,055,000m^2), export cable footprint (cables and protection systems; 11,745m^2), array

cable footprint (cables and protection systems; 30,040m^2), additional cable protection material (4,860m^2), cable tails (120m^2), trench for 9 x landfall cables (7,400m^2), footprint of navigation marker buoys (540m^2), footprint of Acoustic Doppler Current Profiler (ADCP) moorings (280m^2), footprint of seabed mounted environmental monitoring units (112m^2) and footprint of mooring for floating environmental monitoring units (45m^2).

715. The magnitude of the potential displacement due to changes in prey availability as a result of permanent habitat loss is assessed as **negligible / very low** for all species, with less than 1% of all relevant reference populations anticipated to be exposed to the effect (**Table 12-98**).

Table 12-98 Number of individuals (and % of reference population) that could be impacted by any changes of prey availability as a result of permanent habitat loss at MDZ

Potential Impact	Maximum number of individuals and (% of reference population)	Magnitude
Displacement of harbour porpoise due to changes in prey availability	1.71 individuals (based on density estimate of 0.783/ km^2) (0.0016% of the 104,695 reference population).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Displacement of bottlenose dolphin due to changes in prey availability	0.04 individuals (based on density estimate of 0.02/ km^2) (0.011% of the reference population of 397 bottlenose dolphin).	Long-term effect low magnitude (between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Displacement of Risso's dolphin due to changes in prey availability	0.07 individuals (based on density estimate of 0.031/ km^2) (0.0008% of the reference population of 8,794 Risso's dolphin).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Displacement of common dolphin due to changes in prey availability	0.48 individuals (based on density estimate of 0.22/ km^2) (0.00085% of the reference population of 56,556 common dolphin).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Displacement of minke whale due to changes in prey availability	0.04 individuals (based on density estimate of 0.017/ km^2) (0.0016% of the reference population of 23,528 minke whale).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Displacement of grey seal due to changes in prey availability	0.34 individuals (based on density estimate of 0.155/ km^2) (0.006% of the reference population of 6,000 grey seal).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Displacement of harbour seal due to changes in prey availability	0.001 individuals (based on density estimate of 0.0005/ km^2) (0.002% of the reference population of 50 harbour seal).	Long-term effect with negligible / very low magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).

716. The assessment in **Chapter 10, Fish and Shellfish Ecology**, determined that the potential impacts of permanent habitat loss on prey species would result in a low magnitude of the effect, coupled with the medium sensitivity of the receptors, the

impact significance was assessed as minor adverse. No mitigation measures were considered to be required.

12.6.4.12.3. Prey Impacts from Barrier Effects

717. Barrier effects to the movements of fish and shellfish through the water column can arise during the Project due to the presence of tidal devices and associated infrastructure, including mooring chains and catenaries. The worst-case scenario (arising during full site deployment) assessed in **Chapter 10, Fish and Shellfish Ecology** was for the swept area of TEC's of 84,500m^2 based on seabed-mounted multiple rotor platform device types with rotors up to 27m in diameter. However, the assessment found it unlikely to present a complete barrier to fish due to the separation distance (70m distance in the shortest dimension).

718. The assessment in **Chapter 10, Fish and Shellfish Ecology**, determined that the potential impacts of any barrier effects on prey species would result in a medium magnitude of the effect and coupled with the low sensitivity of the receptor there is a minor adverse impact. No mitigation measures were considered to be required.

719. For marine mammals, the potential magnitude for any changes in prey availability is considered to be low, taking into marine sensitivity to changes in prey availability, the impact significance has been assessed as minor (not significant) for all species (**Table 12-99**).

12.6.4.12.4. Prey Impacts from Collision Risk

720. Collision risks can arise from fish coming into contact with the operational tidal devices. The area within which collision risk could occur is equivalent to the maximum swept area (84,500m^2).

721. As outlined in **Chapter 10, Fish and Shellfish Ecology**, it can be assumed that if fatal collisions do occur, it is likely to only be to a small proportion of individuals and not result in a population level effect. The loss of individuals, in the context of the total loss of individuals for a population, are considered to be within the natural levels of mortality due to other factors, therefore the magnitude of the effect at a population was considered to be very low/negligible.

722. Therefore, the combination of a low sensitivity and a very low/negligible magnitude results in a negligible impact significance. However, due to the uncertainty over this assessment, the impact significance was augmented to minor adverse as a precautionary measure.

723. For marine mammals, the potential magnitude for any changes in prey availability is considered to be low, taking into marine sensitivity to changes in prey availability, the impact significance has been assessed as minor (not significant) for all marine mammal species (**Table 12-99**).

12.6.4.12.5. Prey Impacts from Electromagnetic Fields

724. The potential impact of EMF on prey would be the same as those assessed for marine mammals in **Section 12.6.4.9**.

725. The assessment in **Chapter 10, Fish and Shellfish Ecology**, has determined that the potential impacts of any EMF effects on prey species would result in a low magnitude of the effect and coupled with the low sensitivity of the receptor there is a minor adverse impact. No mitigation measures were considered to be required, other than the proposed cable protection.

726. For marine mammals, the potential magnitude for any changes in prey availability is considered to be low, taking into marine sensitivity to changes in prey availability, the impact significance has been assessed as minor (not significant) for all marine mammal species (**Table 12-99**).

12.6.4.12.6. Prey Impacts from Repowering

727. The potential impacts would be the same or less than those assessed for construction in **Sections 12.6.3.8.1**, **12.6.3.8.2** and **12.6.3.8.3**.

728. For marine mammals, the potential magnitude for any changes in prey availability is considered to be negligible / very low, taking into marine sensitivity to changes in prey availability, the impact significance has been assessed as negligible to minor (not significant) for marine mammal species (**Table 12-99**).

12.6.4.12.7. Mitigation

729. No mitigation measures are required or proposed.

12.6.4.12.8. Residual Impact

730. The residual impact would remain negligible or minor (not significant), as detailed in Table 12.99, below.

Table 12-99 Assessment of impact significance for any displacement as a result of any changes to prey availability during operation at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Displacement due to underwater noise impact on prey species	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Negligible / very low	Negligible		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible
Displacement due to permanent habitat loss impact on prey species	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Low	Minor (not significant)		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible
Displacement due to changes in prey availability from barrier effects	Harbour porpoise	Low to medium	Low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Risso's dolphin	Medium	Low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Minke whale	Medium	Low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Low	Minor (not significant)		Minor (not significant)
Displacement due to changes in prey availability from collision risk	Harbour porpoise	Low to medium	Low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Risso's dolphin	Medium	Low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Minke whale	Medium	Low	Minor (not significant)		Minor (not significant)

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
	Grey and harbour seal	Low	Low	Minor (not significant)		Minor (not significant)
Displacement due to changes in prey availability from EMF	Harbour porpoise	Low to medium	Low	Minor (not significant)	None required or proposed	Minor (not significant)
	Bottlenose dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Risso's dolphin	Medium	Low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Low	Minor (not significant)		Minor (not significant)
	Minke whale	Medium	Low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Low	Minor (not significant)		Minor (not significant)
Displacement due changers in prey availability from repowering	Harbour porpoise	Low to medium	Negligible / very low	Negligible to Minor (not significant)	None required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Negligible / very low	Negligible		Negligible
	Risso's dolphin	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Common dolphin	Low	Negligible / very low	Negligible		Negligible
	Minke whale	Medium	Negligible / very low	Minor (not significant)		Minor (not significant)
	Grey and harbour seal	Low	Negligible / very low	Negligible		Negligible

12.6.4.13. Overall Potential Disturbance During Operation

731. The overall maximum area of possible disturbance during ADD activation in-combination with the underwater noise from the operational turbines would be the same area as assessed for ADDs, for example, up to 31.4 km^2 if ten ADDs were activated at the same time (**Table 12-73**), as the area of disturbance would be greater than the area of potential disturbance for underwater noise from operational turbines for the full deployment of up to 11.7 km^2 for harbour porpoise, 0.28 km^2 for dolphin species, 5 km^2 for minke whale and 0.18 km^2 for seals (**Table 12-66**).

732. As a precautionary approach the maximum area of potential disturbance has been assessed for underwater water noise from operational turbines for the full deployment (240MW; **Table 12-66**) at the same time as underwater water noise from any maintenance, repowering and vessels, based on the worst-case scenarios and

maximum potential impact ranges for two drilling activities, two cable laying activities, two cable protection activities and up to 16 vessels (**Table 12-53**). However, during maintenance and repowering activities it is likely that a number of devices or array(s) would be none operational.

733. The magnitude of the long-term effect for the overall potential disturbance is assessed as low for harbour porpoise and very low / negligible for all other species (**Table 12-100**).

Table 12-100 Maximum number of individuals (and % of reference population) that could be disturbed as a result of underwater from maintenance, repowering, vessels and operational tidal devices at MDZ

Potential Impact	**Maximum number of individuals and (% of reference population)**			**Magnitude**
	Maintenance, repowering and vessels	**Full deployment* (possible strong avoidance ($90dB_{ht}$))**	**Total (maximum based on worst-case scenario)**	
Disturbance of harbour porpoise	6.2 individuals in 7.89 km^2 (based on density estimate of 0.783/ km^2) (0.006% of the 104,695 reference population).	9.2 individuals in 11.7 km^2 (0.009% of MU)	15.4 individuals in 19.59 km^2 (0.015% of MU)	Long term effect with low magnitude (with between 0.01% and 1% of the reference population anticipated to be exposed to effect).
Disturbance of bottlenose dolphin	0.002 individuals in 0.12 km^2 (based on density estimate of 0.02/ km^2) (0.0006% of the reference population of 397 bottlenose dolphin).	0.006 individuals in 0.28 km^2 (0.0015% for MU)	0.008 individuals in 0.4 km^2 (0.002% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of Risso's dolphin	0.004 individuals in 0.12 km^2 (based on density estimate of 0.031/ km^2) (0.00004% of the reference population of 8,794 Risso's dolphin).	0.009 individuals in 0.28 km^2 (0.0001% for MU)	0.013 individuals in 0.4 km^2 (0.00015% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).

Potential Impact	Maximum number of individuals and (% of reference population)			Magnitude
	Maintenance, repowering and vessels	**Full deployment* (possible strong avoidance ($90dB_{ht}$))**	**Total (maximum based on worst-case scenario)**	
Disturbance of common dolphin	0.03 individuals in 0.12 km^2 (based on density estimate of 0.22/ km^2) (0.00005% of the reference population of 56,556 common dolphin).	0.06 individuals in 0.28 km^2 (0.0001% for MU)	0.09 individuals in 0.4 km^2 (0.00016% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of minke whale	0.45 individuals in 26.35 km^2 (based on density estimate of 0.017/ km^2) (0.0019% of the reference population of 23,528 minke whale).	0.0085 individuals in 5 km^2 (0.0004% for MU)	0.9 individuals in 31.35 km^2 (0.004% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of grey seal	0.08 individuals in 0.52 km^2 (based on density estimate of 0.155/ km^2) (0.001% of the reference population of 6,000 grey seal).	0.03 individuals in 0.18 km^2 (0.0005% for MU)	0.11 individuals in 0.7 km^2 (0.0018% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).
Disturbance of harbour seal	0.0003 individuals in 0.52 km^2 (based on density estimate of 0.0005/ km^2) (0.0005% of the reference population of 50 harbour seal).	0.00009 individuals in 0.18 km^2 (0.00018% for MU)	0.00039 individuals in 0.7 km^2 (0.0008% of MU)	Long-term effect with very low / negligible magnitude (less than 0.01% of the reference population anticipated to be exposed to effect).

734. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact; **Table 12-6**) and the potential magnitude of the effect, the impact significance (based in the impact significance matrix (**Table 12-9**) and as defined in **Table 12-10**) for any possible long-term disturbance in harbour porpoise has been assessed as **minor (not significant)** and **negligible** for bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal (**Table 12-101**).

Table 12-101 Assessment of impact significance for long-term disturbance of marine mammals from underwater noise from maintenance, repowering, vessels and operational tidal devices at MDZ

Potential Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Disturbance from maintenance, repowering, vessels and operational tidal devices	Harbour porpoise	Low	Low	Minor	No mitigation required or proposed.	Minor (not significant)
	Bottlenose dolphin		Very low / negligible	Negligible		Negligible
	Risso's dolphin		Very low / negligible	Negligible		Negligible
	Common dolphin		Very low / negligible	Negligible		Negligible
	Minke whale		Very low / negligible	Negligible		Negligible
	Grey and harbour seal		Very low / negligible	Negligible		Negligible

12.6.4.13.1. Mitigation

735. No mitigation measures are required or proposed.

12.6.4.13.2. Residual Impact

736. The residual impact would remain minor (not significant) for harbour porpoise and negligible for all other species for the potential overall disturbance from maintenance, repowering, vessels and operational turbines.

12.6.5. Assessment of Potential Impacts During Decommissioning

12.6.5.1. Underwater Noise and Disturbance

737. Decommissioning would most likely involve the removal of the accessible installed components comprising: all of the tidal device components; part of the foundations (those above seabed level); and the sections of the array cables close to the offshore structures, as well as sections of the export cables. The process for removal of foundations is generally the reverse of the installation process. There would be no drilling, but foundations may be cut to an appropriate level.

738. It is not possible to provide details of the methods that will be used during decommissioning at this time. However, is it expected that the activity levels will be comparable to construction (with the exception of drilling noise which would not occur).

739. For this assessment it is assumed that the potential impacts from underwater noise during decommissioning would be comparable or less than those assessed for drilling (**Section 12.6.3.1**), other construction activities (**Section 12.6.3.2**), vessels (**Section 12.6.3.3**) and potential barrier effects (**Section 12.6.3.4**).

12.6.5.2. Disturbance at Seal Haul-Out Sites

740. For this assessment, it is assumed that the potential impacts from any disturbance at seal haul-out sites during decommissioning would be comparable or less than those assessed for construction (**Section 12.6.3.5**).

12.6.5.3. Possible Increased Collision Risk with Vessels

741. For this assessment, it is assumed that the potential impacts from possible increased collision risk with vessels during decommissioning would be comparable or less than those assessed for construction (**Section 12.6.3.6**).

12.6.5.4. Potential Changes in Water Quality

742. For this assessment, it is assumed that the potential impacts from any changes in water quality during decommissioning would be comparable or less than those assessed for construction (**Section 12.6.3.7**).

12.6.5.5. Potential Changes in Prey Availability

743. For this assessment, it is assumed that the potential impacts from potential changes in prey availability during decommissioning would be comparable or less than those assessed for construction (**Section 12.6.3.8**).

12.6.5.6. Mitigation

744. It is proposed the MMMPs would be prepared for decommissioning activities that could have potential underwater noise impacts, such as the removal of tidal devices and cables. These MMMPs would be similar to those proposed in **Sections 12.6.3.1.2.1.1** and **12.6.3.2.2.1.1**.

745. To reduce any potential impacts from changes in water quality, mitigation would include adherence to project-specific EMPs and MPCPs.

12.6.5.7. Residual Impacts

746. The residual impact would be the same as for construction, negligible or minor adverse.

12.6.6. Assessment of Potential Cumulative Impacts

12.6.6.1. Screening for Cumulative Impacts

747. The potential effects from the Project that were screened in for assessment for the project alone were further screened for the potential for cumulative effects with other projects. This process is detailed in **Table 12-102**.

Table 12-102 Cumulative Impact Assessment screening for marine mammals

Impact	Potential for Cumulative Impact	Confidence of Prediction	Justification
Underwater noise and disturbance	Yes	High	There is the potential for cumulative impacts from underwater noise, such as construction activities and vessels from other projects which could have a cumulative impact on marine mammals. A number of projects have been identified that have the potential for cumulative impacts and therefore a more detailed assessment will be carried out for construction, operation and decommissioning impacts of other projects. There is no potential for cumulative impacts for auditory injury as MMMPs for each project will reduce the risk of PTS and therefore any potential cumulative impacts.
Potential barrier effects	No	High	It has been identified that there is no potential for cumulative barrier impacts with other projects, based on the location and distances of the projects.
Disturbance at seal haul-out sites	No	High	No projects have been identified that have the potential for cumulative impacts on the seal haul-out site near the MDZ and ECC.
Increased collision risk with vessels	Yes	High	There is the potential for an increased risk of collision with vessels from a number of different projects, and therefore a more detailed assessment will be carried out for construction, operation and decommissioning impacts of other projects.
Potential changes in water quality	No	High	There is no potential for any changes to water quality to impact on marine mammal species in and around the MDZ and ECC, therefore there is no potential for cumulative impacts with other projects.
Potential changes in prey availability from habitat loss	Yes	High	There is the potential for changes to prey availability to impact on marine mammal species from a number of other projects, therefore a more detailed assessment will be carried out for construction, operation and decommissioning impacts of other projects.
Collision risk with tidal devices	Yes	High	It has been identified that there is the potential for collision risk from tidal devices from at least one other project, and therefore a more detailed assessment will be carried out for the operational impacts of other projects.
Potential entanglement with moorings for floating devices	Yes	High	It has been identified that there is the potential for entanglement from the mooring of floating devices from at least one other project, and therefore a more detailed

Impact	Potential for Cumulative Impact	Confidence of Prediction	Justification
			assessment will be carried out for the operational impacts of other projects.
Potential EMF impacts	No	High	It has been identified that there is no potential for EMF impacts to marine mammal species.

748. A number of cumulative impacts have been identified to have the potential to impact on marine mammal species as identified within **Table 12-102**, and are assessed further in the following sections.

12.6.6.2. Projects Considered for Cumulative Impacts

749. The classes of projects that were considered for the cumulative assessment of marine mammals include offshore wind farms, other marine renewable energy projects, marine aggregate extraction, any oil and gas exploration and extraction, port and harbour projects, subsea cables and pipelines. Only those projects that have had their application submitted or approved, are currently being constructed or are in their operational phases have been considered. Some additional projects have been included if there is enough information available prior to their submission. For projects that are operational, only those potential impacts from operational, maintenance and decommissioning activities are considered.

750. The identification of projects included in the cumulative assessment has been based on approved plans, constructed projects, approved but as yet unconstructed projects, projects for which an application has been made, are currently under consideration and may be consented. In addition, other '"foreseeable" projects are included: those for which an application has not been made but have been the subject of consultation by the developer, or those are listed in plans that have clear delivery mechanisms. For such projects, the absence of robust or relevant data could preclude a quantitative cumulative assessment being carried out.

751. Any projects which have been ongoing since the collection of baseline data (e.g. Holyhead Harbour Maintenance Dredging) are considered part of the baseline.

752. The projects identified have only been assessed for those species that are within the identified Management Unit that is included in the assessments. An indication has been made as to which marine mammal species each Project with the potential for cumulative impact has been included for.

753. A summary of projects considered for CIA and their potential for cumulative impacts is presented in **Table 12-103**.

Table 12-103 Summary of projects considered in CIA and potential for cumulative impacts

Project	Status	Species MU area	Distance from Nearest Part of Project (km)	Potential for Cumulative Impacts							
				Underwater noise and disturbance	Collision risk from vessels	Collision risk from tidal devices	Changes in water quality	Changes to prey availability	Potential for entanglement with moored devices	Potential for EMF impacts	Potential for barrier effects
Holyhead Deep Phase I	In April 2017, a Marine Licence was granted for the first 0.5 MW installation.	All	2	Yes	Yes	Yes	No	No	No	No	No
Holyhead Deep Tidal Array	In 2017, scoping report submitted for an 80MW extension to the Holyhead Deep tidal array.	All	2	Yes	Yes	Yes	No	Yes	No	No	No
Holyhead Port Expansion	ES currently being prepared	All	2	Yes	Yes	N/A	No	Yes	No	No	No
Holyhead Waterfront Regeneration	Awarded Outline Planning Permission in 2014, with Reserved Matters.	All	2	Yes	Yes	N/A	No	No	No	No	No
Wylfa Nuclear Power Plant	Project Suspended	All	17	Yes	Yes	N/A	No	Yes	No	No	No
Wylfa Decommissioning	Ongoing (most work on land)	All	17	Yes	Yes	N/A	No	Yes	No	No	No
Amlwch LNG	The existing consent was renewed in 2013, but future plans are unclear and timescales undefined.	All	20.5	Yes	Yes	N/A	No	No	No	No	No

Project	Status	Species MU area	Distance from Nearest Part of Project (km)	Potential for Cumulative Impacts							
				Underwater noise and disturbance	Collision risk from vessels	Collision risk from tidal devices	Changes in water quality	Changes to prey availability	Potential for entanglement with moored devices	Potential for EMF impacts	Potential for barrier effects
North Hoyle Offshore Wind Farm	Operation and Maintenance Activities only.	All	81	Yes	No	N/A	No	No	N/A	No	No
Rhyl Flats Offshore Windfarm	Operation and Maintenance Activities only.	All	59	Yes	Yes	N/A	No	No	N/A	No	No

12.6.6.3. Cumulative Impact Assessment

754. The quantitative cumulative impact assessment for marine mammals has been conducted for underwater noise and disturbance (**Table 12-104**), collision risk with tidal devices and vessels (**Table 12-105**) and changes in prey availability as a result of habitat loss (**Table 12-106**).

755. Changes in prey availability as a result of any potential disturbance from underwater noise would be less that areas of potential impact assessed for marine mammals and would therefore have no further potential cumulative impacts.

756. As no instances of entanglement with the mooring systems of renewable energy have been recorded, and the constant tension of the mooring line for the Holyhead Deep Phase I, the impact was concluded to be negligible for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin and grey seal, and low for minke whale. Taking into account the assessment of potential entanglement at MDZ (**Section 12.6.4.8**), there is no predicted cumulative effects.

757. To take into account the movement of grey and harbour seal and locations of the projects in the cumulative impact assessment (i.e. not all located in the South and West England and the Wales MU) the assessments of disturbance from underwater noise and collision risk with tidal devices and vessels have been put into the context of the 40,233 grey seal and 31,549 harbour seal in the wider OSPAR region (based on Russell *et a*l., 2017).

Table 12-104 Cumulative impact assessment for potential disturbance of harbour porpoise (HP), bottlenose dolphin (BND), Risso's dolphin (RD), common dolphin (CD), minke whale (MW), grey seal (GS) and harbour seal (HS) from underwater noise (N/A = not available)

Project	Potential Cumulative Impact	Notes	Assessment of Cumulative Impact (maximum number of individuals potentially displaced)						
			HP	BND	RD	CD	MW	GS	HS
		For the installation of one DGU piling activities are likely to be limited to approximately 5 days, the ES concluded that there is likely to be very limited interaction between the piling noise and mammals; any changes would likely be undetectable against natural variation and would have no residual impact at the population level. However, as a worst-case scenario the number of marine mammals in the 10 km range (314 km^2 area) has been estimated, based on the density estimates in the ES for HP, BND, CD & MW and the MDZ density estimates for RD, GS and HS, this area would include construction vessels.							
Holyhead Deep Tidal Array – 80MW	Underwater noise and potential disturbance from construction vessels	Assumed to be the same as assessment in ES for single device that disturbance ranges for marine mammals from vessel noise could be 14 km for installation / construction vessel (using DP) and up to 4 km for support vessels. No numbers of individuals provided in the ES. However, the ES concluded that whilst a small number of individual animals may exhibit some form of change	0	0	0	0	0	0	0

	operation and maintenance activities	mammals over and above normal shipping activities.							
Walney Extension Offshore Wind Farm[10]	Underwater noise and disturbance during operation and maintenance activities	As noise associated with the WTGs through operation are temporary, of a low level and area localised in nature, the impact was assessed to be negligible. Due to the low level of noise associated with maintenance vessels, and the low level of activity required compared to existing baseline levels, it is considered that there would no additional impacts to marine mammals.	0	0	0	0	0	0	0
Burbo Bank Extension Offshore Wind Farm[11]	Underwater noise and disturbance during operation and maintenance activities	Impacts associated with turbine operating noise are considered to be direct and continuous. It is predicted that marine mammals will quickly habituate to the presence of turbines in the water, and that there will be sufficient distance between turbines to allow movement between foundations. The impact is therefore considered to be of neutral significance.	0	0	0	0	0	0	0

Project	Potential Cumulative Impact	Notes	Assessment of Cumulative Impact (maximum number of individuals potentially displaced)						
			HP	BND	RD	CD	MW	GS	HS
		cause behavioural effects in seals, harbour porpoise and dolphin species. It is expected that these noise levels would attenuate quickly from source. Given that only three piles are to be installed, the rapid attenuation of the noise, and therefore the impact is considered to be temporary, local and of minor significance. The only additional vessel movements through the operational phase would be the occasional maintenance dredging vessel. No additional vessel movements are expected at the new ferry terminal above current levels. Based on these considerations, the impact is expected to be temporary, local and of negligible significance.

Project	Potential Cumulative Impact	Notes	Assessment of Cumulative Impact (maximum number of individuals potentially displaced)						
			HP	BND	RD	CD	MW	GS	HS
		Operational tidal devices can emit low levels of noise. However, considering that marine mammals have the capacity to avoid, adapt to, accommodate and recover from the impact of noise, and the indications of low levels of effect from the monitoring at Strangford Lough tidal turbine, the impact was assessed as negligible.							
Sound of Islay Demonstration Site[16]	Underwater noise and disturbance	Due to the number of vessels already using the area, and the limited duration over which increased levels of construction vessel activity will occur, as well as the existing levels of background noise, the impact is expected to be relatively low. A negligible magnitude is predicted for construction noise, with no measurable response or change anticipated. During operation, the Islands of Islay and Jura will have a shielding effect on noise levels and is not likely to travel out of the Sound.	0	0	0	0	0	0	0

[16] http://marine.gov.scot/datafiles/lot/So_Islay_Tidal/2014_Application/Environmental%20Report/Volume%201_%202010%20Sound%20of%20Islay%20Environmental%20Statement.pdf

Project	Potential Cumulative Impact	Notes	Assessment of Cumulative Impact (maximum number of individuals potentially displaced)						
			HP	BND	RD	CD	MW	GS	HS
		Data from other tidal projects has not shown any significant effect on the activity of marine mammals in the area. With regard to maintenance activities, it is expected that marine mammals in the area will be accustomed to vessel noise. Noise effects from maintenance vessels (if any) are expected to be both short term, limited in scale and transitory. Based on levels of existing noise and the limited scale of potential noise impacts, operational noise is predicted to be limited.							
West of Islay Tidal Energy Park[17]	Underwater noise and disturbance	Not in HP MU, but in GS and HS OSPAR region (CD, RD & MW not assessed). Disturbance from underwater noise was assessed as negligible to minor.	-	-	-	-	-	0	0

		short duration (i.e. only when vessel is present). Therefore, it is not considered that there would be any additional impacts to marine mammals over and above normal shipping activities and extremely unlikely that any vessel collision will occur.							
Codling Wind Park	Collision risk with vessels	No information available to inform assessment.	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Codling Bank Extension	Collision risk with vessels	No information available to inform assessment.	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Isle of Man Ferry Terminal	Collision risk with vessels	The vessels involved in the construction phase would be small and once on site are expected to remain relatively stationary. The risk of a collision with marine mammals is considered to be extremely small. As the only increase in vessels at the site is expected to be from occasional maintenance dredging, the potential for increased collision risk through the operation of the Ferry terminal is not expected to be any greater than current shipping activities and it is extremely unlikely that any vessel collision will occur.	0	0	0	0	0	0	0
Milford Haven, Maintenance Dredge Pembrokeshire	Collision risk with vessels	No information available to inform assessment.	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Afon Dysynni outfall gravel removal and relocation	Collision risk with vessels	No information available to inform assessment.	N/A	N/A	N/A	N/A	N/A	N/A	N/A
Belfast Harbour D3 terminal cruise ship facility	Collision risk with vessels	The probability of a collision occurring is considered to be low as, while collision incidents have been recorded in the UK and Ireland, they are generally considered to be a rare occurrence. In addition, construction activities are only short term and temporary. The conclusion is that there would be a negligible impact on marine mammal species.	0	0	0	0	0	0	0
Marine Energy Wales marine testing area	Collision risk with tidal devices	Scoping. No information available to inform assessment.	N/A	N/A	N/A	N/A	N/A	N/A	N/A

Project	Potential Cumulative Impact	Notes	Assessment of Cumulative Impact (maximum number of individuals at increased risk)						
			HP	BND	RD	CD	MW	GS	HS
	Collision risk with vessels		N/A	N/A	N/A	N/A	N/A	N/A	N/A
Argyll Tidal Demonstration	Collision risk with tidal devices	Based on a modelling of other tidal arrays which assessed the impact of collision risk to be negligible for cetaceans, the impact of collision on marine mammal populations can also be assessed as negligible for this project. No values for the collision risk of individuals for each species was provided.	-	-	N/A	N/A	N/A	N/A	N/A
	Collision risk with vessels	Construction vessels are likely to be moving slowly, indicating a lower collision risk than from other vessels already in the area. The risk of collision is considered to be low as numbers of individuals in the area are low, and construction activities would be expected to require only a short period of activity. No values for the collision risk of individuals for each species was provided.	-	-	N/A	N/A	N/A	N/A	N/A
Sound of Islay Demonstration Site	Collision risk with tidal devices	The noise generated by the devices during operation could be detected up to a distance of between 20 and 400m and is expected to alert mammals to the presence of the devices when they are operating at full power and enable avoidance measures to be taken. This, along with the environmental awareness and manoeuvrability of marine mammals, the relatively slow movement of the rotors on each device, are all a factor in the impact assessment. No values for the collision risk of individuals for each species was provided.	-	-	N/A	N/A	N/A	N/A	N/A
	Collision risk with vessels	Based on existing levels of vessel activity in the area, the limited scale and timeframe for installation, as well as the lack of any evidence of collision risk from other tidal turbine installation works, impact is therefore predicted to be minor.	-	-	N/A	N/A	N/A	N/A	N/A

12.6.6.3.1. Impact Significance for Cumulative Impacts

758. Taking into account the low sensitivity to any disturbance (i.e. has some tolerance to avoid, adapt to, accommodate or recover from the anticipated impact) and the potential magnitude of the effect, the impact significance for disturbance from cumulative underwater noise has been assessed as **negligible** for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour (**Table 12-107**).

759. The impact significance for any cumulative collision risk with tidal devices and vessels has been assessed as **minor (not significant)** for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal, without any mitigation, taking into account the receptor sensitivity and magnitude of effect (**Table 12-107**).

760. As outlined in **Section 12.6.4.5.5**, the potential population level effects of collision risk with operational tidal turbines on marine mammals have been assessed in **Appendix 12.2** (**Volume III**). The result of the PVA indicate that population trajectories of the baseline and collision risk scenarios of 1, 2 and 3 animals are very similar, with only a potential for a decline when more than three adults per year are removed from the population of 397 bottlenose dolphins in the Irish Sea MU.

761. The impact significance for any cumulative displacement due to changes in prey availability as a result of habitat loss has been assessed as **negligible to minor (not significant)** for harbour porpoise, **negligible** for common dolphin and harbour seal and **minor (not significant)** for bottlenose dolphin and grey seal, taking into account the receptor sensitivity and magnitude of effect (**Table 12-107**).

Table 12-107 Assessment of impact significance for potential cumulative impacts

Potential Cumulative Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Underwater noise and disturbance	Harbour porpoise	Low	Negligible	Negligible	No further mitigation proposed	Negligible
	Bottlenose dolphin		Negligible	Negligible		Negligible
	Risso's dolphin		Negligible	Negligible		Negligible
	Common dolphin		Negligible	Negligible		Negligible
	Minke whale		Negligible	Negligible		Negligible
	Grey seal		Negligible	Negligible		Negligible
	Harbour seal		Negligible	Negligible		Negligible
Collision risk with tidal devices and vessels	Harbour porpoise	Low	Medium	Minor	Phased deployment, monitoring and mitigation	Minor (not significant)
	Bottlenose dolphin		Medium	Minor		Minor (not significant)
	Risso's dolphin		Medium	Minor		Minor (not significant)
	Common dolphin		Medium	Minor		Minor (not significant)
	Minke whale		Medium	Minor		Minor (not significant)
	Grey seal		Medium	Minor		Minor (not significant)
	Harbour seal		Medium	Minor		Minor (not significant)

Potential Cumulative Impact	Receptor	Sensitivity	Magnitude	Significance	Mitigation	Residual Impact
Displacement due to changes in prey availability as a result of habitat loss	Harbour porpoise	Low to medium	Negligible	Negligible to Minor	No mitigation required or proposed	Negligible to Minor (not significant)
	Bottlenose dolphin	Low	Low	Minor		Minor (not significant)
	Risso's dolphin	Medium	Negligible	Minor		Minor (not significant)
	Common dolphin	Low	Negligible	Negligible		Negligible
	Minke whale	Medium	Negligible	Minor		Minor (not significant)
	Grey seal	Low	Low	Minor		Minor (not significant)
	Harbour seal	Low	Negligible	Negligible		Negligible

12.6.6.3.2. Mitigation

762. No further mitigation measures are proposed, other than those already outlined for the Morlais project, including MMMPs and the phased deployment, monitoring and mitigation.

12.6.6.3.3. Residual Impact

763. The residual impact for disturbance from cumulative underwater noise would remain **negligible** for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal.

764. The residual impact for any cumulative displacement due to changes in prey availability as a result of habitat loss would remain **negligible to minor (not significant)** for harbour porpoise, **negligible** for common dolphin and harbour seal and **minor (not significant)** for bottlenose dolphin and grey seal.

765. With the propose phased deployment, monitoring and mitigation at Morlais, the residual impact would be **minor (not significant)** for harbour porpoise, bottlenose dolphin, Risso's dolphin, common dolphin, minke whale, grey seal and harbour seal.

12.7. SUMMARY

766. **Table 12-108** summarises the impact assessments undertaken for marine mammals. Throughout the construction, operation and maintenance, repowering, and decommissioning phases, taking into account the proposed mitigation, the impact on marine mammals is considered to be of negligible or minor adverse significance. The only exception is the potential collision risk of bottlenose dolphin with operational turbines, which has been precautionarily assessed as potentially minor to moderate adverse. This reflects the small number of individuals in the area, however, the potential risk is likely to be lower as bottlenose dolphins have not been recorded in the MDZ and are more likely to move along the coast than through the MDZ array area.

Table 12-108: Summary of potential impacts on marine mammals
